VOLUME XXIV.

TAI-WAN——TITLARKS.

LONDON:

CHARLES KNIGHT AND Co., 22, LUDGATE STREET.

MDCCCXLII.

Price Seven Shillings and Sixpence, bound in cloth.

COMMITTEE.

Chairman—The Right Hon. LORD BROUGHAM, F.R.S., Member of the National Institute of France.

Vice-Chairman—The Right Hon. EARL SPENCER.

Treasurer—JOHN WOOD, Esq.

William Allen, Esq., F.R. and R.A.S.
Captain Beaufort, R.N., F.R. and R.A.S.
George Burrows, M.D.
Professor Carey, A.M.
John Cassilly, M.D.
William Couisson, Esq.
The Right Rev. the Bishop of St. David's, D.D.
J. F. Davis, Esq., F.R.S.
Sir Henry De la Beche, F.R.S.
The Right Hon. Lord Denman.
Samuel Duckworth, Esq.
The Right Rev. the Bishop of Durham, D.D.
T. F. Ellis, Esq. A.M., F.R.A.S.
John Elliotson, M.D., F.R.S.
Thomas Falconer, Esq.
John Forbes, M.D., F.R.S.
Sir J. L. Goldsmid, Bart., F.R. and R.A.S.
Francis Henry Goldsmid, Esq.

B. Gompertz, Esq., F.R. and R.A.S.
Professor Graves, A.M., F.R.S.
G. B. Greenough, Esq., F.R. and L.S.
Sir Edmund Head, Bart., A.M.
M. D. Hill, Esq., Q.C.
Rowland Hill, Esq., F.R.A.S.
Right Hon. Sir J. C. Hobhouse, Bart., M.P.
Thos. Hodgkin, M.D.
David Jardine, Esq., A.M.
Henry B. Ker, Esq.
Professor Key, A.M.
Sir Denis Le Marchant, Bart.
Sir Charles Lemon, Bart., M.P.
George C. Lewis, Esq., A.M.
James Loch, Esq., M.P., F.G.S.
George Long, Esq., A.M.
Professor Malden, A.M.
A. T. Malkin, Esq., A.M.

Mr. Sergeant Manning.
R. I. Murchison, Esq., F.R.S., F.G.S.
The Right Hon. Lord Nugent.
W. S. O'Brien, Esq., M.P.
Professor Quain.
P. M. Roget, M.D. Sec. R.S., F.R.A.S.

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

TAI-WAN (*Taiwan*) is the Chinese name of an island which in Europe is known by the name of Formosa, and Hermosa, and, according to the Dutchman Valentyn, is called by the aborigines Pekan or Pæk-and. It lies between 21° 58′ and 25° 15′ N. lat., and between 120° and 122° E long., and extends from south by west to north by east about 240 miles. In width it varies much. From its most southern point, where it is only about four miles wide, it increases gradually, so that at 23° N. lat. it is 60 miles wide, and at 24° N. lat. nearly 100 miles. Its northern portion decreases in width, but very slowly, for near its northern end it is still 60 miles wide. A rough calculation gives the surface an extent of about 14,000 square miles, which is about half the area of Ireland, and 3000 square miles more than that of Sicily.

The north-western point of Taï-wan is only about 80 miles from the coast of the Chinese province of Fukian, or Fokian; but farther south the channel of Fokian, as the sea between Taï-wan and China is called, grows wider. In the parallel of Amoy, 24° 40′ N. lat., it is 150 miles across, and still wider south of that parallel. This part of the China Sea contains several banks, and the soundings are also extremely irregular, especially in the vicinity of the Ponghu or Phenghu Islands, called also Pescadores, or Fisher Islands. The southern extremity of Taï-wan is divided from the Bashee Islands, which are south-east of it, by the channel of Formosa, which is nearly 80 miles wide, and has also very irregular soundings.

The broad promontory which terminates the island on the south, and forms the south-east and south-west cape, is a low flat, but at the distance of about two miles the country suddenly rises into mountains, which continue to run in an unbroken chain northward nearly through the middle of the island to its northern extremity, terminating with high cliffs at the north-east cape. As it is certain that this range of mountains, which is called Ta Shan, or Great Mountain, is nearly the whole year round covered with snow, its elevation has been estimated by Humboldt at about 12,000 feet above the sea. The declivities of these mountains, with the exception of the crests of the most elevated portion, are covered with fine trees and pasture-grounds, and thus the island, when seen from the sea, presents a very pleasing appearance, whence it was called Hermosa by the Europeans who advanced thus far into the Indian Sea. These mountains have never been visited by Europeans, but from the accounts of the Chinese geographers, which have been collected by Klaproth, it appears that there is more than one volcano on this island. The Tshykang (Red Mountain), south of the town of Fung-shan-hian, was once an active volcano, and there is still a lake of hot water on Shin Mountains. The Phy-nan-my-shan, south-east of Fung-shan-hian, emits in the night-time a brilliant lustre. The Ho-shan (Fire-Mountain), south-east of Tshu-lo-hian, is said to contain many wells from which flames issue. There are some other mountains which exhibit traces of volcanic action, and sulphur constitutes an important article of export.

The mountains have a steep declivity on both sides, but on the west side they terminate at a considerable distance from the sea, so as to leave a wide tract between them and the shore. This tract has an undulating surface, and terminates on the sea in a low sandy beach. The adjoining sea is full of sand-banks and shoals, and can only be approached in a few places by vessels drawing more than eight feet of water. On the east of the Ta-shan range the mountains seem to occupy nearly the whole space between the crest of the range and the sea, and high rocks line the shore. There are no soundings along this coast. This circumstance, united to the strong current which sets along this side from south to north, is probably the reason why this part of Taï-wan has never been visited by European vessels; nor does it appear that Japanese or Chinese vessels have any intercourse with this part of the island. It is an unknown portion of the globe.

Rivers are numerous on the west side, but as they originate in a very elevated region, from which they descend in continuous rapids and cataracts, they bring down a considerable quantity of earthy matter, which they deposit at their mouths, forming bars, which have so little water as to admit only small vessels: this however seems to be no great disadvantage, as there are numerous islands along the shore, between which junks of ordinary size (about 200 tons burden) find good anchorage. Some of the rivers however are said to be navigable for a considerable distance inland, especially the Tan-shuy-khy, which falls into the Tan-shuy-kiang Bay, which lies in the narrow part of the channel of Fukian. The rivers also offer the great advantage of an abundant irrigation, though they are sometimes destructive to the crops by their inundations.

No portion of the ocean is subject to such violent gales as the sea surrounding Taï-wan on the west and east. Both monsoons, the north-eastern and the south-western, blow in the direction of the channel of Fukian, and as they are confined between two high mountain-ranges, the mountains of Fukian and of Taï-wan, their violence is much increased. At the change of the monsoons the most violent gales come on suddenly, and are accompanied by typhons, whirlwinds, and waterspouts. Many Chinese vessels are annually lost at these seasons. The Japan Sea, which lies north of Taï-wan, is noted for its terrible tempests. In the vicinity of the island the north-eastern monsoon generally lasts nine months, as it continues to blow to the beginning of June. In other respects the climate of the island is very temperate, neither the heat nor the cold being excessive on the plains along the western coast. The island is subject to earthquakes, and they are sometimes very violent. In 1782 the whole lower portion was laid waste, and the sea inundated the country to the base of the mountains for

twelve hours. A great part of the capital was destroyed, and some hundreds of junks were lost.

The soil of the lower tracts and the more gentle slopes of the mountains is very fertile, and produces abundance of corn, which is exported to the harbours of Fukian, of which the island is said to be the granary. It produces rice of excellent quality; also wheat, millet, maize, and several kinds of vegetables, among which are truffles. The sugar-cane is extensively cultivated, and the sugar made in the island goes to China, as far as Peking. Orchards are carefully attended to. They produce oranges, pine-apples, guavas, cocoa-nuts, areca-nuts, jack-fruit, and other fruits found in the East Indies; also peaches, apricots, figs, grapes, pomegranates, and chestnuts. Melons are also much grown. Only green tea is cultivated, and it is stated that it forms an article of export to China, where it is used as a medicine. The blossoms of the wild jasmine are dried and exported to China, where they are used to give a scent to the tea. Other articles of export are camphor, pepper, aloes, and timber. Timber abounds in the large forests in the northern districts of the island. It is also stated that coffee, cotton, and silk are produced to a small amount.

The domestic animals are cattle, buffaloes, horses, asses, and goats, but sheep and hogs are rare. The horses are small, and the Chinese find them unfit for their cavalry. It is said that on the eastern unknown portion of the island there are many beasts of prey, as tigers, leopards, and wolves, but they are not found on the western side, where wild hogs, deer, monkeys, pheasants, and game are very abundant. Salt is made to a great extent, and, together with sulphur, forms a large article of export.

The population consists of Chinese settlers and of aborigines. The Chinese are only found on the west side of the island, where they first settled a hundred and eighty years ago (1662). Their number many years ago was stated to be about 500,000 individuals. They are mostly from Fukian, and have preserved the customs of their original country, and the spirit of industry and enterprise by which their countrymen are distinguished. A considerable number of aborigines are settled among the Chinese, to whom they are subject, and are obliged to pay a tribute in corn and money. The collectors of the tribute are Chinese, who are required to know the language of the aborigines for the purpose of explaining to them the orders of the court. It is said that the oppression to which the aborigines are subject from these interpreters frequently causes them to rise in rebellion. These aborigines are of a slender make, and in complexion resemble the Malays, but they do not differ from the Chinese in features. Their language shows that they belong to the widely spread race of the Malay nations; and it is said that they greatly resemble the Horaforas of the Moluccas. Their religion resembles what is called Shamanism. The Dutch took some steps to convert them to Christianity, but their sway on the island was too limited and of too short a duration to produce any lasting effect. Nothing is known of the aborigines who inhabit the east side of the island. They are not subject to the Chinese, and are said to be continually at war with them. Inhabiting a country covered with lofty mountains, they are said to subsist mostly on the produce of the chase and by fishing.

The Chinese portion of Taï-wan is divided into four districts, which, from south to north, are Fung-shan-hian, Taï-wan-hian, Tshul-lo-hian, and Thang-hua-hian. The capital, Taï-wan-fu, is a considerable place, and has a garrison of 10,000 troops. The wall was built in 1725. The streets are straight, and intersect one another at right angles: they are full of shops, which are abundantly provided with all articles of Chinese industry. The largest building is that which was erected by the Dutch during their short sway in Taï-wan. There is still a small church built by the Dutch. It is stated that 1000 junks can anchor in the harbour; but as the single entrance, at spring-tides, has but from nine to ten feet of water, only vessels of moderate size can enter it. There was formerly another entrance, which had a greater depth of water, and for the protection of which the Dutch had built the fortress of Zelandia; but it is said that this entrance has been filled up with sand. The commerce of this place with China is considerable. Wu-teaou-kiang, which was visited by Lindsay in 1832, has a harbour, which was then crowded with junks and numerous coasting vessels which brought the produce of the country, especially rice and sugar, to this place. Tan-shuy-kiang, at the embouchure of the river Tan-shuy-khy, is at the innermost recess of a fine bay, which is large enough for a numerous fleet, but has not been visited by Europeans. The best harbour is near the northern extremity of the island, and is called Ky-long-shai: the Dutch call it Quelong. It is capacious enough to contain 30 large vessels, and is the station of the Chinese navy at the island. An active commerce is carried on at this place.

The commerce of the island is limited to that with the eastern provinces of China, especially Fukian, to which it sends its agricultural produce, with sulphur and salt, and from which it imports tea, raw silk, woollen and cotton stuffs, and other manufactures. It is stated that the number of junks that annually enter the ports amounts to more than 1000. The navigation of the channel of Fukian, though difficult on account of the gales and the rough sea, is rendered much less so by the situation of the Ponghu Islands, which offer a safe refuge in time of danger. These rocky islands are thirty-six in number, most of them very small, and a few somewhat larger. The largest has an excellent harbour, in which vessels of between nine and ten feet draught may anchor in security. The Chinese have erected some fortifications on them, as they have occasionally been taken possession of by pirates, who frequently infest the adjacent coast of China.

Opposite the southern extremity of the eastern coast of Taï-wan is the island of Botol Tabago-xima. It is elevated, and about ten miles in circumference. It is surrounded by a sea without soundings, and no navigator has ever landed on it. It is said to be very populous.

It appears that the island of Taï-wan was known to the Chinese and Japanese at an early period, but they did not settle on it nor subject it to their sway. When the Dutch appeared in these seas, following the track of the Portuguese, they found no Chinese settlement either on the Ponghu Islands or on Taï-wan. They erected some fortification on the Ponghu Islands, and in 1634 they built the fortress of Zelandia at the entrance of the harbour of Taïwan-fu, where there was then a small town. They built also a small fortress at the harbour of Ky-long-shaï. The protection which was thus offered to emigrants induced a large number of families from Fukian to settle in the island, and the colony rose rapidly in importance. Meanwhile China was laid waste by the wars which terminated in the overthrow of the Ming dynasty and the establishment of the present family on the throne. The adherents of the former dynasty maintained their footing longest in the eastern and southern provinces, Chekiang, Fukian, and Quangtun, but being pressed by their enemies, they abandoned the mainland, and continued the war on the sea. One of their chiefs, Tshing-tshing-kung, called by the Europeans Koxinga, sailed, after the loss of a battle, to the Ponghu Islands, and occupied them. Hence he proceeded to Taï-wan, and finding only a very weak garrison in the Dutch fortress, he took it, after a siege of four months, in 1662. Thus the Dutch lost the island, after having been in possession of it for twenty-eight years. Tshing-tshing-kung, the new king of Taï-wan, favoured the settling of his countrymen, the inhabitants of Fukian, and thus the island in a short time was converted into a Chinese colony. He was also favourable to the English, who had, during his reign, a commercial establishment on the island, from which they carried on an active commerce with Amoy. The province of Fukian, which continued its opposition to the victorious Mantchoos longer than any other part of China, had been compelled to submit to their sway; and as Tshing-tshing-kung had died, and the throne of Taï-wan was occupied by a minor, a Chinese fleet in 1682 took possession of the Ponghu Islands. The Chinese were also preparing a descent on Taï-wan, when, in 1683, the council which governed in the name of the young prince thought it most prudent to surrender the island to the court of Peking without a war.

(Père du Mailla, *Lettres édifiantes et curieuses*, vol. xviii.; Klaproth's *Description de l'Isle de Formose, extraite de livres Chinois*, in *Mémoires relatifs à l'Asie;* La Pérouse, *Voyage autour du Monde;* and Lindsay's *Voyage of the vessel Amherst along the coast of China*, in *Parliamentary Reports*, 1831.)

TALAPOINS is the name given by the Portuguese, and after them by other European nations, to the Buddhist

priests, or rather monks, of Siam, and is supposed to be derived from the fan which they always carry, usually made of a leaf of the palmyra-tree, and hence, says Crawfurd (*Journal of Embassy to Siam*, p. 358), denominated by the Sanscrit word *Tulpat*. Tal is the common Indian name for the palmyra; and the older travellers give Talapa as the Siamese word for a fan. In the Pali (or learned tongue) the Talapoins of Siam are said to be called Thaynka; but in the common language of the country they are spoken of, as well as to, simply by the term Chau-cou, or Chau-ca, which signifies My lord (or literally Lord of me), the first of the two forms being that commonly used, the other that employed to express extraordinary inferiority on the part of the speaker. (La Loubere, *Du Royaume de Siam*, i. 407.) Mr. Crawfurd states that they are called Phra, which he says is a Pali word signifying Lord, applied also to Gautama or Buddha, to the king, to the white elephant, to the idols of Buddha, &c. By the Burmese the Talapoins are said to be called Rahans, whence seems to come the name Raulins, given to them by the Mohammedans; as by the Chinese they are called Ho-changi; in Tibet, Lama-seng or Lamas; and in Japan, Bonzes. (Prevost, *Histoire Générale des Voyages*, vi. 328; and Dr. Fr. Buchanan, 'On the Religion and Literature of the Burmas,' in *Asiatic Researches*, vol. vi.) In Ceylon the name for the ordinary priests is stated to be Tirounnanse; but, as the novices are said to be styled Saman Eroo Ounnanse, and certain inspectors, exercising a general superintendence over the temples, Naïke Ounnanse and Mahanaïke Ounnanse, it would seem that the name for priests of all kinds is Ounnanse. (Joinville, 'On the Religion and Manners of the People of Ceylon,' in *Asiatic Researches*, vol. vii.) Samana, or Somona, according to Dr. Buchanan, is a title given in Burma both to the priests and to the images of Buddha; whence the Buddhists are often called Samanians. It is derived, he says, from the Sanscrit word Saman, signifying gentleness or affability.

Ample information on the subject of the Talapoins is given by La Loubere, who visited Siam in 1687-8, in quality of envoy from the French king, in his work entitled 'Du Royaume de Siam,' 2 vols. 12mo., Amsterdam, 1691, vol. i., chaps. 17, 18, 19, 21, pp. 341-368 and 381-426; and by Mr. Crawfurd, in his 'Journal of an Embassy from the Governor-General of India to the Courts of Siam and Cochin China' (in 1821-22), 4to., London, 1828, pp. 350, &c. They are, as has been stated, a species of monks living in communities of from ten to some hundreds, and employing their time in devotion, religious study, and meditation, and in begging, or rather receiving alms, for they are not permitted actually to solicit charity. Their monasteries, in which each monk has his separate cell, are always adjoining to some temple; but it does not appear that the Talapoins officiate as priests or ministers of religion in our sense of the term. Neither are they considered as forming or belonging to the literary or learned class: the pursuit of any secular study is looked upon as unseemly and profane in a Talapoin; and in fact they are mostly very ignorant. Yet the instruction of youth in the elements of learning appears to be chiefly or exclusively in their hands. Every Siamese, we are told, becomes a Talapoin for some time. 'Every male in the kingdom,' says Mr. Crawfurd, 'must at one period or another of his life enter the priesthood, for however short a time. Even the king will be a priest for two or three days, going about for alms like the rest, and the highest officers of the government continue in the priesthood for some months.' Usually, it may be supposed, a man goes through the ceremony of getting himself made a talapoin without any intention of permanently forsaking the world; but if he enters one of the sacred communities a second time, he cannot again withdraw from it. The Talapoins are said to be very numerous; but they seem to consist for the greater part of mere temporary members of the order, and of persons who have thus entered it for the second time in advanced life. Its advantages, or temptations, are, a life of idleness, exemption from taxation and from the conscription, security of subsistence and comfortable raiment, together with the ceremonious marks of respect with which a talapoin is everywhere treated. All the monasteries are endowed by the government, or by wealthy individuals, under whose protection they are considered to be. La Loubere has given a drawing of one; and another is described in Finlayson's account of 'The Mission to Siam and Hué in 1821-22,' p. 110. In their dresses of yellow cotton or silk, which are of the same fashion with those of the Buddhist priests in Ava and Ceylon, the Talapoins of Siam present a highly favourable contrast to the rags and squalidity of the general population. On the other hand, a talapoin is not only separated from society by being condemned to celibacy, and is prohibited from possessing property, but is expected to observe very strictly several of the precepts of the national religion which are very little attended to by anybody else, especially the prohibitions against the slaying of animals (although they will eat them when slain), stealing, adultery, lying, and drinking wine. There are different orders of Talapoins, and La Loubere says there are also female Talapoins, whom he calls Talapouines; but these, according to Crawfurd, are only a few old women who are allowed to live in the unoccupied cells of some of the monasteries. The national head of the Talapoins, styled the Son-krat, is appointed to that dignity by the king, and always resides in the royal palace.

TALAVE'RA DE LA REYNA, or LA REAL, a large town of Spain, formerly in the province of Toledo, but now, since the late division of the Spanish territory, the capital of the province of its name. It is situated on the right bank of the Tagus, at the end of an extensive and well cultivated plain, 38° 52′ N. lat., 6° 39′ W. long. It was called by the Romans Ebora Talabriga, as the inscriptions and remains found in its territory show. It has a fine Gothic church, the foundation of the celebrated Rodrigo Ximenez, archbishop of Toledo, the author of a history of the Arabs and a Latin chronicle of Spain, about the beginning of the thirteenth century. The town is badly built, and the streets are narrow and crooked. The population does not exceed 12,000, who are chiefly occupied in the manufacture of pottery and hardware, for which Talavera is famous all over Spain. A large silk manufactory, which belongs to the government, employs also many of the population. In July, 1809, Talavera was the scene of a battle between the British under Wellington (then General Wellesley) and the French commanded by Jourdan. The battle was long and obstinately contested, but it ended in the complete defeat of the French. The exhausted condition of the English troops, who were without provisions, prevented them from following up their advantage and pursuing the enemy. There is another town, in La Mancha, called Talavera la Vieja, or 'the old.'

TALC, a mineral which occurs crystallized and massive, and it is probable that some distinct species of minerals have been so called. Primary form of the crystal a rhomboid, but usually occurs in the secondary form of hexagonal laminæ, and sometimes in long prisms. Cleavage distinct, perpendicular to the axis. It is easily separable into thin plates, which are flexible, but not elastic. It is easily scraped with a knife, and the powder is unctuous to the touch. Colour white, green, greyish, and blackish-green and red. Becomes negatively electrical by friction; lustre pearly. Transparent; translucent; opaque. Specific gravity 2·713.

Crystallized talc is mostly white, or of a light green colour; is met with in serpentine rocks in small quantity, with carbonate of lime, actinolite, steatite, and massive talc, &c. It is found in the mountains of Salzburg and the Tyrol: it occurs in many other parts of the world, as in Cornwall, in Kynan's Cove, where a bed of it underlies serpentine. It also occurs in Scotland, in Glen Tilt, Perthshire; and in Saxony, Silesia, and Piedmont, &c.

The *massive varieties* of talc are less flexible than the crystallized: they are principally of an apple-green colour, and sometimes of a radiated structure. It is met with in considerable quantity in beds in micaceous schistus, gneiss, and serpentine.

Some of the varieties of talc are infusible; others become white, and yield a small button of enamel with borax.

Indurated talc is massive, of a greenish grey colour; the structure is schistose and curved: it is of a shining and sometimes of a pearly lustre, and somewhat translucent. It is soft and rather unctuous to the touch. Its specific gravity is 2·9.

It occurs in primitive mountains in clay slate and serpentine, in several countries on the continent of Europe; in Britain, in Perthshire and Banffshire in Scotland, and in the Shetland Islands.

According to Vauquelin, lamellar talc consists of

Silica	62
Magnesia	27
Alumina	1·8
Oxide of iron	3·2
Water	6
	100·

Steatite, chlorite, and other magnesian minerals are nearly allied to mica, and they are by some mineralogists considered as varieties of the same substance.

TALEGALLA. Mr. G. R. Gray makes the *Megapodiinæ* the third and last subfamily of his *Palamedeidæ* (Palamedea, Linn.).

The *Megapodiinæ* comprise the following genera:—*Talegalla*, Less. (*Alectura*, Lath.; *Talegallus*, Less.; *Numida*, James; *Catheturus*, Sw.); *Megapodius*, Quoy et Gaim. [Megapodiidæ; Cracidæ, vol. viii., p. 132]; *Mesites?* J. Geoffr.; *Menura*, Shaw (*Parkinsonius*, Bechst.; *Megapodius*, Wagl.) [Menuræ]; *Alecthelia*, Less. (nec Swains.) [Cracidæ, vol. viii., p. 133].

We proceed in this article to notice the genera *Talegalla*, *Leipoa*, and *Megapodius*, the natural history of which, especially with regard to their habits and nidification, has lately been satisfactorily made out.

And first of

Talegalla.

Generic Character.—Bill very robust, very thick, one-third of the length of the head compressed above, with the upper mandible convex; nostrils basal, lateral, oval-oblong, piereed in a large membrane; lower mandible less high but wider than the upper, nearly straight below, with smooth edges, the branches widened at the base, and that width filled up by a feathered membrane; cheeks entirely naked; head and neck furnished with feathers with simple barbules. Wings rounded, moderate, the first quill very short, the second rather longer, the third longest of all, the fourth and fifth diminishing in length after the third. Tail rather long, rounded; tarsi rather robust, moderately long, furnished with large scutella in front; toes rather long, the middle longest, the external shortest; the three front toes furnished at their origin with a membranous border, which is widest between the external and middle toes; claws convex, flattened below, slightly curved and moderately robust; the hind-toe long, resting entirely on the ground, and furnished with an equally robust claw. (Lesson.)

Head and foot of Talegalla. (Gould.)

Example, *Talegalla Lathami*.

Latham, in his *General History of Birds* (vol. i.), described and figured this bird under the name of the *New Holland Vulture*; but, correcting his error, he, in the tenth volume, placed it among the Gallinaceous Birds, with the generic name of *Alectura*, which had been previously employed to designate a group of Flycatchers.

M. Lesson places the genus at the end of the *Phasianidæ*.

Mr. Swainson, in his *Classification of Birds* (vol. i., 1836), treating of the *Vulturidæ*, notices this species, under the name of the New Holland Vulture, as being so like a rasorial bird, that some authors have hesitated (not having seen a specimen) as to what order it really belonged. 'So completely indeed,' says he, 'has nature disguised this rare and extraordinary vulture in the semblance of that type which it is to represent in its own family, that it has even been classed by one writer with the *Menura* of the same Continent; and it must be confessed that if clear conceptions of the difference between analogy and affinity are not entertained, such a classification has some plausible reasons to recommend it. In fact, the feet of the two birds are formed nearly on the same principle; but, then, so are those of *Orthonyx*, a little scansorial bird not much bigger than a robin. All three genera, in short, are remarkable for their large disproportionable feet, long and slightly curved claws, and the equality of length, or nearly so, of the outer and the middle toe. It is by instances such as these that we perceive the full extent of those unnatural combinations which result from founding our notions of classification from one set of characters, and forgetting to look at the full consequences of carrying those notions into extended operation. Nor is this the only peculiarity of the New Holland Vulture; for, unlike all others of its family, it possesses eighteen feathers in its tail. 'An examination of the bill,' Mr. Swainson gives a cut of it, 'which is decidedly raptorial, joined with many other considerations, shows that all these are but analogical relations to the *Rasores*, while the real affinities of the bird are in the circle of the *Vulturidæ*, of which it forms the rasorial type. A perfect specimen of this very rare vulture, now before us (procured by Mr. Allan Cunningham in the forests adjoining Van Diemen's Land), enables us to speak of its structure from personal examination.' In the synopsis to Mr. Swainson's second volume (1837), we find it in the family *Vulturidæ*, under the name of *Catheturus* (which cannot be retained), between *Neophron* and *Gypaetus*, recorded as the rasorial type of the *Vulturidæ*. And yet it is no bird of prey at all. Latham, in his tenth volume, and Lesson, were right in considering it a rasorial species.

Mr. Gould, to whom we are indebted for a full and satisfactory account of the habits of this extraordinary bird, to which we shall presently advert, modestly says:—'After all the facts that have been stated, I trust it will be evident that its natural situation is among the *Rasores*, and that it forms one of a great family of birds peculiar to Australia and the Indian Islands, of which *Megapodius* forms a part; and in confirmation of this view I may add, that the sternum has the two deep emarginations so truly characteristic of the *Gallinaceæ*; at all events it is in no way allied to the *Vulturidæ*, and is nearly as far removed from *Menura*.' It seems to us that *Talegalla Lathami* may be considered, in a degree, as the representative of the turkey in Australia.

Description.—Adult *male*: whole of the upper surface, wings, and tail, blackish-brown; the feathers of the under surface blackish-brown at the base, becoming silvery-grey at the tip; skin of the head and neck deep pink-red, thinly sprinkled with short hair-like blackish-brown feathers; wattle bright yellow, tinged with red where it unites with the red of the neck; bill black; irides and feet brown.

Female about a fourth less than the male in size, but so closely the same in colour as to render a separate description unnecessary. She also possesses the wattle, but not to so great an extent. (Gould.)

Size about that of a turkey.

Mr. Gould gives the following synonyms:—*New Holland Vulture*, Lath.; genus *Alectura*, ibid.; *Alectura Lathami*, J. E. Gray; *New Holland Vulture*, *Catheturus Australis*, Sw.; *Meleagris Lindesaygii*, Jameson; *Brush Turkey* of the colonists; *Weelah* of the aborigines of the Namoi.

Habits, Nidification, &c.—Mr. Gould describes *Talegalla Lathami*, or the *Wattled Talegalla*, as a gregarious bird, generally moving about in small companies, much after the manner of the *Gallinaceæ*, and, like some species of that tribe, as very shy and distrustful. When it is disturbed, he states that it readily eludes pursuit by the facility with which it runs through the tangled brush. If hard pressed, or where rushed upon by their great enemy, the native dog, the whole company spring upon the lowermost bough of some neighbouring tree, and, by a succession of leaps from branch to branch, ascend to the top, and either perch there or fly off to another part of the brush. They resort also to the branches of trees as a shelter from the sun in the middle of the day, a habit which Mr. Gould notices as greatly tending to their destruction; for the sportsman is enabled to take a sure aim, and the birds, like the ruffed grouse of America, will allow a succession of shots to be fired till they are all brought down.

But the most remarkable circumstance connected with the economy of this bird is its nidification, for it does not

hatch its eggs by incubation. It collects together a great heap of decaying vegetables as the place of deposit of its eggs, thus making a hot-bed, arising from the decomposition of the collected matter, by the heat of which the young are hatched. Mr. Gould describes this heap as the result of several weeks' collection by the birds previous to the period of laying, as varying in quantity from two to four cart-loads, and as of a perfectly pyramidical form. This mound, he states, is not the work of a single pair of birds, but is the result of the united labour of many: the same site appeared to Mr. Gould to be resorted to for several years in succession, from the great size and entire decomposition of the lower part, the birds adding a fresh supply of materials on each occasion previous to laying.

'The mode,' says Mr. Gould in continuation, 'in which the materials composing these mounds are accumulated is equally singular, the bird never using its bill, but always grasping a quantity in its foot, throwing it backwards to one common centre, and thus clearing the surface of the ground for a considerable distance so completely, that scarcely a leaf or a blade of grass is left. The heap being accumulated, and time allowed for a sufficient heat to be engendered, the eggs are deposited, not side by side, as is ordinarily the case, but planted at the distance of nine or twelve inches from each other, and buried at nearly an arm's depth, perfectly upright, with the large end upwards: they are covered up as they are laid, and allowed to remain until hatched. I have been credibly informed, both by natives and settlers living near their haunts, that it is not an unusual event to obtain nearly a bushel of eggs at one time from a single heap; and as they are delicious eating, they are eagerly sought after. Some of the natives state that the females are constantly in the neighbourhood of the heap about the time the young are likely to be hatched, and frequently uncover and cover them up again, apparently for the purpose of assisting those that may have appeared; while others have informed me that the eggs are merely deposited, and the young allowed to force their way unassisted. In all probability, as nature has adopted this mode of reproduction, she has also furnished the tender birds with the power of sustaining themselves from the earliest period; and the great size of the egg would equally lead to this conclusion, since in so large a space it is reasonable to suppose that the bird would be much more developed than is usually found in eggs of smaller dimensions. In further confirmation of this point, I may add, that in searching for eggs in one of the mounds, I discovered the remains of a young bird, apparently just excluded from the shell, and which was clothed with feathers, not with down, as is usually the case: it is to be hoped that those who are resident in Australia, in situations favourable for investigating the subject, will direct their attention to the further elucidation of these interesting points. The upright position of the eggs tends to strengthen the opinion that they are never disturbed after being deposited, as it is well known that the eggs of birds which are placed horizontally are frequently turned during incubation. Although, unfortunately, I was almost too late for the breeding-season, I nevertheless saw several of the heaps, both in the interior and at Illawarra: in every instance they were placed in the most retired and shady glens, and on the slope of a hill, the part above the nest being scratched clean, while all below remained untouched, as if the birds had found it more easy to convey the materials down than to throw them up. In one instance only was I fortunate enough to find a perfect egg, although the shells of many from which the young had been excluded were placed in the manner I have described. At Illawarra they were rather deposited in the light vegetable mould than among the leaves, which formed a considerable heap above them. The eggs are perfectly white, of a long, oval form, three inches and three-quarters long by two inches and a half in diameter.' (*Birds of Australia.*)

The same author relates that these birds, while stalking about the wood, frequently utter a loud clucking noise; and, in various parts of the bush, he observed depressions in the earth, which the natives informed him were made by the birds in dusting themselves. The stomach is stated by Mr. Gould to be extremely muscular; and he found the crop of one which he dissected filled with seeds, berries, and a few insects.

The composure with which these birds sit to be shot at, as above noticed, must, as Mr. Gould observes, lead to an early extinction of the race; an event, he remarks, much to be regretted, since, independently of its being an interesting bird for the aviary, its flesh is extremely delicate, tender, and juicy. There is no doubt that this species may be domesticated, and it would make a noble addition to those foreign denizens of the poultry-yard which enrich our homesteads and tables. Mr. Gould saw a living specimen, which was in the possession of Mr. Alexander M'Leay for many years. 'On my arrival at Sydney,' says Mr. Gould, 'this venerable gentleman took me into his garden and showed me the bird, which, as if in its native woods, had for two successive years collected an immense mass of materials similar to those above described. The borders, lawn, and shrubbery over which it was allowed to range presented an appearance as if regularly swept, from the bird having scratched to one common centre everything that lay upon the surface: the mound in this case was about three feet and a half high, and ten feet over. On placing my arm in it, I found the heat to be about 90° or 95° Fahr. The bird itself was strutting about with a proud and majestic air, sometimes parading round the heap, at others perching on the top, and displaying its brilliantly coloured neck and wattle to the greatest advantage: this wattle it has the power of expanding and contracting at will; at one moment it is scarcely visible, while at another it is extremely prominent.'

Before Mr. Gould left New South Wales, this bird, which, during the greater part of the period when it was in Mr. M'Leay's possession, was at large, and usually associated with the fowls in the poultry-yard, was unfortunately drowned in a tank or water-butt. On dissection it was found to be a male, thereby proving, as Mr. Gould remarks, that the sexes are equally employed in forming the mound for the reception of the eggs.

Locality.—Mr. Gould states that the extent of the range of this species over Australia is not yet satisfactorily ascertained. It is known, he says, to inhabit various parts of New South Wales from Cape Howe on the south to Moreton Bay on the north; but the cedar-cutters and others, who so frequently hunt through the brushes of Illawarra and Maitland, have nearly extirpated it from those localities, and it is now most plentiful in the dense and little-trodden brushes of the Manning and Clarence. Mr. Gould was at first led to believe that the country between the mountain-ranges and the coast constituted its sole habitat; but he was agreeably surprised to find it inhabiting the scrubby gullies and sides of the lower hills that branch off from the great range into the interior. He procured specimens on the Brezi range to the north of Liverpool Plains, and ascertained that it was abundant in all the hills on either side of the Namoi. (*Ibid.*)

Talegalla Lathami. (Gould.)

M. Lesson describes the species from New Guinea, which serves as the type of his genus *Talegalla Cuvieri*, figured in the *Zoologie de la Coquille*, as entirely black, of the size of a common small hen, and recalling to the observer some of the forms of the *Porphyriones*. [RALLIDÆ, vol. xix., p. 281.]

The history of *Talegalla* affords a striking instance of the futility of classification based upon reasoning which has no sufficient data for its foundation: most of the errors

of our zoological systems may be traced to the same source.

Leipoa. (Gould.)

Generic Character.—*Bill* nearly as long as the head, slender, tumescent at the base, the edges undulated and incurved at the base, the nostrils ample, oblong, covered with an operculum, and placed in a central hollow. Head

Head and Foot of Leipoa.

suberested. *Wings* ample, rounded, concave; fifth primary quill the longest; the tertiaries nearly as long as the primaries. *Tail* rounded, tail-feathers fourteen. *Tarsi* moderate, robust, covered with scuta anteriorly, and posteriorly with scales which are rounded and unequal. *Toes* rather short; lateral toes nearly equal. (Gould.)

Example, *Leipoa ocellata, Ocellated Leipoa*. (Gould.)

Description.—Head and crest blackish-brown; neck and shoulders dark ash-grey; the fore part of the neck from the chin to the breast marked by a series of lanceolate feathers, which are black with a white stripe down the centre; back and wings conspicuously marked with three distinct bands of greyish white, brown and black near the tip of each feather, the marks assuming an ocellated form, particularly on the tips of the secondaries; primaries brown, their outer webs marked with two or three zigzag lines near their tip; all the under surface light buff, the tips of the flank feathers barred with black; tail blackish-brown, broadly tipped with buff; bill black; feet blackish-brown. (Gould.)

In size this beautiful bird is inferior to *Talegalla Lathami*, and it is more slender and more elegantly formed. According to Mr. Gould, it is the *Ngow* of the aborigines of the lowland; *Ngow-oo* of the mountain districts of Western Australia; and *Native Pheasant* of the colonists of Western Australia.

Habits, Food, Nidification, &c.—Mr. Gould, in his *Birds of Australia*, gives an account, collected by Mr. John Gilbert, from G. Moore, Esq., advocate-general, Mr. Armstrong, the aboriginal interpreter, and some of the more intelligent natives of Western Australia. The *Ocellated Leipoa* is there described as a ground-bird, never taking to a tree except when closely hunted: when hard pursued, it will frequently run its head into a bush, and is then easily taken. Food generally consisting of seeds and berries. The note mournful, very like that of a pigeon, but with a more inward tone. Eggs deposited in a mound of sand, the formation of which is the work of both sexes. According to the natives, the birds scratch up the sand for many yards around, forming a mound about three feet in height, the inside of which is constructed of alternate layers of dried leaves, grasses, &c., among which twelve eggs and upwards are deposited, and are covered up by the birds as they are laid; or, as the natives express it, 'the countenances of the eggs are never visible.' Upon these eggs the bird never sits, but when she has laid out her lay, as the henwives say, the whole are covered up, when the mound of sand resembles an ant's nest. The eggs, which are white, very slightly tinged with red, and about the size of a common fowl's egg, are hatched by the heat of the sun's rays, the vegetable lining retaining sufficient warmth during the night; they are deposited in layers, no two eggs being suffered to lie without a division. The natives, who are very fond of the eggs, rob these hillocks two or three times in a season; and they judge of the number of eggs in a mound by the quantity of feathers lying about. If the feathers be abundant, the hillock is full; and then they immediately open and take the whole. The bird will then begin to lay again, again to be robbed, and will frequently lay a third time. Upon questioning one of the men attached to Mr. Moore's expedition, he gave to Mr. Gilbert a similar account of its habits and mode of incubating; adding, that in all the mounds they opened, they found ants almost as numerous as in an ant-hill; and that in many instances that part of the mound surrounding the lower portion of the eggs had become so hard, that they were obliged to chip round them with a chisel to get the eggs out; the insides of the mounds were always hot.

Captain Grey, of the 83rd regiment, who had just returned from his expedition to the north-west coast, informed Mr. Gould that he had never fallen in with the nests but in one description of country, viz. where the soil was dry and sandy and so thickly wooded with a species of dwarf *Leptospermum*, that if the traveller strays from the native paths, it is almost impossible for him to force his way through. In these close scrubby woods small open glades occasionally occur, and there the Ngow-oo constructs its nest,—a large heap of sand, dead grass and boughs, at least nine feet in diameter and three feet in height; Captain Grey had seen them even larger than this. Upon one occasion only he saw eggs in these nests: they were placed some distance from each other, and buried in the earth. Captain Grey states that he is not sure of the number, but the account given by the natives led him to believe that at times large numbers were found.

Locality.—Western Australia. Mr. Moore saw a great many of them about sixty miles north of Perth; but its most favourite country appears to be the barren sandy plains of the interior, 100 miles north and east of York. The farthest point north at which Captain Grey saw the breeding-places was Gantheaume Bay. Captain Grey states that the natives of King George's Sound say that the same or a nearly allied species exists in that neighbourhood. (*Birds of Australia.*)

Leipoa Ocellata. (Gould.)

Megapodius.

In the article Cracidæ (vol. viii., p. 132) the generic character of *Megapodius* and an account of *Megapodius Duperreyi* is given. It is there stated that it would seem that the Megapodius of the Philippines leaves its eggs to the fostering heat of the sun. Mr. Gould, in the great work from which we have already drawn such interesting accounts of this extraordinary group of birds, has, from the notes of Mr. Gilbert, laid before the public a most satisfactory statement relative to the habits of *Megapodius Tumulus*.

Head and foot of Megapodius. (Gould.)

Description.—Head and crest very deep cinnamon-brown; back of the neck and all the under surface very dark grey; back and wings cinnamon-brown; upper and under tail-coverts dark chestnut-brown; tail blackish-brown; irides generally dark brown, but in some specimens light reddish-brown; bill reddish-brown, with yellow

edges; tarsi and feet bright orange, the scales on the front of the tarsi from the fourth downwards, and the scales of the toes, dark reddish-brown. (Gould.)

Size about that of a common fowl.

This is the *Ooregoorgā* of the aborigines of the Cobourg Peninsula; the *Jungle-fowl* of the colonists of Port Essington.

Habits, Food, Nidification, &c.—On Mr. Gilbert's arrival at Port Essington his attention was attracted to numerous great mounds of earth which were pointed out to him by some of the residents as being the tumuli of the aborigines. The natives, on the other hand, assured him that they were formed by the Jungle-fowl for the purpose of hatching its eggs. But this last statement appeared so extraordinary, and so much at variance with the general habits of birds, that no one in the settlement believed them, and the great size of the eggs brought in by them as the produce of this bird strengthened the doubt of the veracity of their information. Mr. Gilbert however, knowing the habits of *Leipoa*, took with him an intelligent native, and proceeded about the middle of November to Knocker's Bay, a part of Port Essington harbour comparatively but little known, and where he had been informed a number of these birds were to be seen. He landed beside a thicket, and had not advanced far from the shore when he came to a mound of sand and shells, with a slight mixture of black soil, the base resting on a sandy beach, only a few feet above high-water mark: it was enveloped in the large yellow-blossomed *Hibiscus*, was of a conical form, twenty feet in circumference at the base, and about five feet high. On asking the native what it was, he replied, 'Oregoorgā Rambal' (Jungle-fowl's house or nest). Mr. Gilbert scrambled up the sides of it, and found a young bird in a hole about two feet deep; the nestling, apparently only a few days old, was lying on a few dry withered leaves. The native assured Mr. Gilbert that it would be of no use to look for eggs, as there were no traces of the old birds having lately been there. Mr. Gilbert took the utmost care of the young bird, placed it in a moderate-sized box, into which he introduced a large portion of sand, and fed it on bruised Indian corn, which it took rather freely. Its disposition was wild and intractable, and it effected its escape on the third day. While it remained in captivity, it was incessantly employed in scratching up the sand into heaps, and Mr. Gilbert remarks that the rapidity with which it threw the sand from one end of the box to the other was quite surprising for so young and small a bird, its size not being larger than that of a small quail. At night it was so restless that Mr. Gilbert was constantly kept awake by the noise it made in endeavouring to escape. In scratching up the sand the bird only employed one foot, and having grasped a handful as it were, threw the sand behind it with but little apparent exertion, and without shifting its standing position on the other leg: this habit, Mr. Gilbert observes, seemed to be the result of an innate restless disposition and a desire to use its powerful feet, and to have but little connection with its feeding; for, although Indian corn was mixed with the sand, Mr. Gilbert never detected the bird in picking any of it up while thus employed.

Mr. Gilbert continued to receive the eggs without any opportunity of seeing them taken from the ground until the beginning of February, when, on again visiting Knocker's Bay, he saw two taken from a depth of six feet, in one of the largest mounds he had met with. In this instance the holes ran down in an oblique direction from the centre towards the outer slope of the hillock, so that although the eggs were six feet deep from the summit, they were only two or three feet from the side. 'The birds,' says Mr. Gilbert in continuation, 'are said to lay but a single egg in each hole, and after the egg is deposited the earth is immediately thrown down lightly until the hole is filled up; the upper part of the mound is then smoothed and rounded over. It is easily known when a Jungle-fowl has been recently excavating, from the distinct impressions of its feet on the top and sides of the mound, and the earth being so lightly thrown over, that with a slender stick the direction of the hole is readily detected, the ease or difficulty of thrusting the stick down indicating the length of time that may have elapsed since the bird's operations. Thus far it is easy enough; but to reach the eggs requires no little exertion and perseverance. The natives dig them up with their hands alone, and only make sufficient room to admit their bodies, and to throw out the earth between their legs; by grubbing with their fingers alone they are enabled to follow the direction of the hole with greater certainty, which will sometimes, at a depth of several feet, turn off abruptly at right angles, its direct course being obstructed by a clump of wood or some other impediment. Their patience is however often put to severe trials. In the present instance the native dug down six times in succession to a depth of at least six or seven feet without finding an egg, and at the last attempt came up in such a state of exhaustion that he refused to try again; but my interest was now too much excited to relinquish the opportunity of verifying the native's statements, and by the offer of an additional reward I induced him to try again: this seventh trial proved successful, and my gratification was complete when the native with equal pride and satisfaction held up an egg, and, after two or three more attempts, produced a second: thus proving how cautious Europeans should be of disregarding the narrations of these poor children of nature, because they happen to sound extraordinary or different from anything with which they were previously acquainted.'

Upon another occasion Mr. Gilbert and his native, after an hour's excessive labour, obtained an egg from the depth of about five feet. It was in a perpendicular position. The holes in this mound (which was fifteen feet high and sixty in circumference at the base, and, like the majority of those that he had seen, so enveloped in thickly foliaged trees as to preclude the possibility of the sun's rays reaching any part of it) commenced at the outer edge of the summit and ran down obliquely towards the centre: their direction therefore, Mr. Gilbert observes, is not uniform. The mound was quite warm to the hands.

How the young effect their escape does not appear; some natives told Mr. Gilbert that the nestlings effected their escape unaided; but others said that the old birds at the proper time scratched down and released them. The natives say that only a single pair of birds are ever found at a mound at a time. Our space will not permit a more detailed account of these highly curious mounds; but the reader should consult Mr. Gould's highly valuable work for other particulars: we can only spare room for Mr. Gilbert's description of the general habits of this interesting species.

'The Jungle-fowl is almost exclusively confined to the dense thickets immediately adjacent to the sea-beach: it appears never to go far inland, except along the banks of creeks. It is always met with in pairs or quite solitary, and feeds on the ground, its food consisting of roots which its powerful claws enable it to scratch up with the utmost facility, and also of seeds, berries, and insects, particularly the larger species of Coleoptera. It is at all times a very difficult bird to procure; for although the rustling noise produced by its stiff pinions when flying away be frequently heard, the bird itself is seldom to be seen. Its flight is heavy and unsustained in the extreme; when first disturbed it invariably flies to a tree, and on alighting stretches out its head and neck in a straight line with its body, remaining in this position as stationary and motionless as the branch upon which it is perched: if however it becomes fairly alarmed, it takes a horizontal but laborious flight for about a hundred yards with its legs hanging down as if broken. I did not myself detect any note or cry, but from the native's description and imitation of it, it much resembles the clucking of the domestic fowl, ending with a scream like that of the peacock. I observed that the birds continued to lay from the latter part of August to March, when I left that part of the country; and, according to the testimony of the natives, there is only an interval of about four or five months, the driest and hottest part of the year, between their seasons of incubation. The composition of the mound appears to influence the colouring of a thin epidermis with which the eggs are covered, and which readily chips off, showing the true shell to be white: those deposited in the black soil are always of a dark reddish-brown; while those from the sandy hillocks near the beach are of a dirty yellowish white: they differ a good deal in size, but in form they all assimilate, both ends being equal: they are three inches and five lines long by two inches and three lines broad.' (*Birds of Australia.*)

Mr. Gould has thus given the history of these three

nearly allied genera, forming, as he observes, part of a great family of birds whose range will be found to extend from the Philippines through the islands of the Indian Archipelago to Australia. *Megapodius Tumulus* is, according to him, rather numerously spread over the whole of the Cobourg Peninsula on the north coast of the Australian continent, where the British settlement of Port Essington is now established; and he thinks that future research will require us to assign to it a much wider range, probably over the whole extent of the north coast.

Megapodius Tumulus, Mound-raising Megapode, with nest in the distance. (From Gould.)

TALENT (τάλαντον) was the highest denomination of Greek weights and money, and was also commonly used by Greek writers as the translation of words signifying a certain weight in other languages. It is necessary to observe that the talent is properly only a denomination of *weight*. There was no coin of that name; and when used in reference to money, it meant originally a talent-weight of gold or silver, and afterwards a certain quantity of current money, the weight of which (supposing the real and nominal value of the coin to be the same) amounted to a talent.

I. The Hebrew Talent, or Kikkar (כִּכָּר), contained 3000 shekels, and, according to Mr. Hussey's computation, its weight was 93 lbs. 12 ozs. avoirdupois, and its value as *silver*-money 396*l.* 5*s.* 10*d.* [Shekel.] The Hebrews had no gold money of their own.

II. The Greek Talent.

The following were the principal denominations of weight and money among the Greeks:—ὀβολός, δραχμή, μνᾶ, τάλαντον, of which the ὀβολός was the smallest. Their relative proportions are shown in the annexed table:—

Obol	Drachma	Mina	
6			
600	100		
36,000	6000	60	Talent.

This system prevailed throughout Greece, but the actual values of the talent varied in different states. Most of these variations may be included under two chief standards, namely, the Attic and the Aeginetan.

1. *The Attic Talent.*—The value of the Attic talent before the time of Solon is a matter on which we possess hardly any historical information, though we may perhaps arrive at a very probable result. Looking then at the system after Solon had remodelled the coinage [Solon], we find that the Attic silver money was celebrated for its purity; and therefore from the coins of that period which still exist we may determine the value of the standard with tolerable certainty. Now the chief coin was the drachma of silver, the average weight of which, from the time of Solon to that of Alexander the Great, is found to be 66·5 grains. From this we get the following values in avoirdupois weight:—

	lb.	oz.	gr.
Obol	..	..	11·08
Drachma	..	..	66·5
Mina	..	15	83·75
Talent	56	15¼	100·32

This was the standard always used for silver money, and was therefore called 'the silver standard.'

Besides this there was another standard, the chief weight of which was called *the commercial mina* (ἡ μνᾶ ἡ ἐμπορική), and contained 138 drachmae, 'according to the standard weights in the silver mint' (see a decree in Böckh, *Corp. Inscrip.*, i. 123, § 4); that is, not that a commercial mina contained 138 *commercial* drachmae, but that this was quite a different standard from that used for silver money, its unit being to that of the latter in the ratio of 138 : 100; while the *relative* proportions of the weights were the same in both systems. The following table shows the value of the Attic commercial standard:—

	lb.	oz.	gr.
Obol	..	..	15·29
Drachma	..	..	91·77
Mina	1	4¼	93·69
Talent	75	5¼	14·69

These weights were used for all commodities, except such as were expressly required by law to be sold by the silver standard.

This commercial standard is most probably, as Böckh has shown, the real antient Attic standard, as it existed before the time of Solon. The purpose of Solon's change was to lower the value of money, in order to relieve debtors. The only direct information we have of the nature of the change is the statement of Plutarch, that 'Solon made the mina of 100 drachmae, which had formerly contained 73,' which is probably a mistake made by Plutarch, through not understanding the words of Androtion, whose authority he follows. The true meaning seems undoubtedly to be, that *out of the same quantity of silver* which in the antient standard made 73 drachmae, Solon coined 100, or a mina; that is, that he lowered the standard in the ratio of 100 : 73. Now the ratio of the commercial to the silver standard is 138 : 100 = 100 : 72$\frac{46}{69}$. Hence the commercial standard and the old Attic only differed by a small fraction.

Still this ratio of 100 : 73 is a very singular one for Solon to have adopted. The most probable explanation is that Solon meant to lower the standard by a quarter, that is, in the ratio of 100 : 75, and that the new coinage (by an accident of not uncommon occurrence in minting) was found, when actually made, to be a little too light, namely, in the ratio of 72$\frac{46}{69}$: 100, or, in round numbers, 73 : 100 to the old money, instead of 75 : 100; and that then, to preserve the purity of the Attic mint, this, its actual value, was adopted as its nominal value.

This view is strongly confirmed by a reference to another standard mentioned by Greek writers, namely, *the Euboïc talent*. This talent was often reckoned as equal to the Attic (compare Herod., iii. 89, with Pollux, ix. 6); but it is also described with greater precision by Aelian (*Var. Hist.*, i. 22), as having to the Attic the ratio of 72 : 70, which is the same as 75 : 72$\frac{11}{12}$. Now if we suppose that the *intended* value of Solon's talent had to its *real* value the ratio of 75 : 72$\frac{46}{69}$, we have this intended value equal (neglecting a very small fraction) to the Euboïc talent. Hence it is inferred that Solon, proposing to lower the Attic standard, and perceiving the advantage of assimilating it to that of the neighbouring island of Euboea, intended to adopt the latter for his new standard, but that in fact a slight difference was caused by accident.

The Romans reckoned both the Attic and Euboïc talents as equal to 80 Roman pounds (compare Polyb. xxi. 14, with xxii. 26, and Liv. xxxvii. 45, with xxxviii. 38).

The Attic commercial standard underwent an alteration by the edict above referred to, which made

its mina = 150 drachmae (silver)
its 5 minae = 6 minae (commercial)
its talent = 65 minae (commercial)

In this new standard the five-minae weight was equal to 7 lb. 13$\frac{1}{2}$ oz. 14·96 grs., and the talent to 85 lbs. 2$\frac{1}{4}$ oz. 70·7 grs.

The Athenians took the greatest care of their standards of weight. The principal set were lodged in the Acropolis, and there were other sets in the Prytaneum, at Piraeus, and at Eleusis.

The highest coin used by the Athenians was the tetradrachm, or piece of four drachmae; the mina and talent were never coined, but were paid in drachmae, oboli, &c. The following table shows the value of all the denominations of Attic silver money, according to the computation of Mr. Hussey:—

	£	s.	d.	farthings.
Chalcus (of copper)				·8125
½ Obol				1·625
¼ Obol				3·25
Obol			1	2·5
Diobolon			3	1
Triobolon			4	3·5
Tetrobolon			6	2
Drachma			9	3
Didrachm		1	7	2
Tetradrachm		3	3	
Mina	4	1	3	
Talent	243	15		

2. *The Aeginetan talent.* It is a disputed question what was the ratio of the Aeginetan to the Attic talent. Pollux (ix. 76, 86) says that the Aeginetan talent contained 10,000 Attic drachmae, and the Aeginetan drachma 10 Attic obols, which would give the ratio of 5 : 3 for that of the Aeginetan to the Attic talent. According to this statement, the Aeginetan drachma weighed 110 grains English. Now the existing coins give an average of only 96 grains; and the question therefore is whether we are to follow Pollux or the coins. Mr. Hussey takes the latter course, explaining the statement of Pollux as referring to the debased drachma of later times, which was about equal to the Roman denarius. Böckh adheres to the statement of Pollux, explaining the lightness of the existing coins by the well-known tendency of the antient mints to depart from the full value. He has supported his view by some very strong and ingenious arguments, and on the whole he appears to be right.

There were other talents used by the Greeks and Romans, most of which seem to have been derived from one of these two standards, but the accounts of antient writers respecting them are very contradictory. Their values are discussed at length by Böckh and Hussey.

The most important variations of the Aeginetan standard were those used in Macedonia, Corinth, and Sicily.

The above talents were all reckoned in silver money. There was also a talent of gold, which was much smaller. It was used chiefly by the Greeks of Italy and Sicily, whence it was called the *Sicilian talent* as well as the *gold talent*. It was equal to 6 Attic drachmae, that is, about ¾ oz. and 71 grs. It was divided by the Italian Greeks into 24 *nummi*, and afterwards into 12, each nummus containing 2½ *litrae*. When Homer uses the word *talent*, we must always understand by it this small one of gold. In other classical writers the word generally means the Attic talent.

(Böckh, *Metrolog. Untersuch.*; Hussey, *Antient Weights and Money; Dictionary of Greek and Roman Antiquities*, 1842.)

TALE'S. At common law, when the number of jurymen in attendance was so small, or so much diminished by challenges that a full jury could not be had, a writ (then in Latin) issued to the sheriff, commanding him to summon *such* (tales) other fit persons, &c. for the purpose of making up the jury. The jurors so procured were called talesmen, from the Latin word used in the writ. By the statute 35 Hen. VIII., c. 6, the defect of jurors might, at the request of the plaintiff or defendant in an action, be supplied from *such* other able persons of the said county then present, and these were ordinarily called, from the words in the Latin writ, 'tales de circumstantibus.' Subsequent statutes extended and regulated the application of this statute. But the act now in force is 6 Geo. IV., c. 50; the 37th section, which contains the existing law on the subject, and is in the following words:—'Where a full jury shall not appear before any court of assize or Nisi prius, or before any of the superior civil courts of the three counties palatine, or before any court of great sessions, or where, after appearance of a full jury, by challenge of any of the parties, the jury is likely to remain untaken for default of jurors, every such court, upon request made for the king by any one thereto authorised or assigned by the court, or on request made by the parties, plaintiff or defendant, demandant or tenant, or their respective attorneys, in any action or suit, whether popular or private, shall command the sheriff or other minister, to whom the making of the return shall belong, to name and appoint, as often as need shall require, so many of *such* other able men of the county then present as shall make up a full jury; and the sheriff or other minister aforesaid shall, at such command of the court, return *such* men duly qualified as shall be present, or can be found to serve on such jury, and shall add and annex their names to the former panel, provided that where a special jury shall have been struck for the trial of any issue, the talesman shall be such as shall be empannelled upon the common jury panel to serve at the same court, if a sufficient number of such men can be found; and the king, by any one so authorised or assigned as aforesaid, and all and every the parties aforesaid, shall and may, in each of the cases aforesaid, have their respective challenges to the jurors so added and annexed, and the court shall proceed to the trial of every such issue with those jurors who were before empannelled, together with the talesmen so newly added and annexed, as if all the said jurors had been returned upon the writ of precept awarded to try the issue.' (2 Williams's Saunders, 349 n. (1).) [JURY.]

TALIACO'TIUS, GASPAR, TAGLIACOZIO, or TAGLIACOZZI, was professor of anatomy and surgery at Bologna, where he died in 1553, at the age of 64 years. His name is now known chiefly through his reputation for restoring lost noses; but during his life he was equally celebrated for his knowledge of anatomy and his excellence as a lecturer. These last are indeed the only qualities for which he is praised in a tablet put up after his death in one of the halls of the school at Bologna. A statue erected in the amphitheatre formerly recorded his skill in operating by representing him with a nose in his hand.

Some writers have spoken of the original Taliacotian operation as a mere fable, pretending that it never could have been followed by success. But several credible witnesses have recorded that they either saw Taliacotius operating, or saw patients to whom he had restored noses, which very closely resembled those of natural formation. The truth is that the operation which Taliacotius really performed is not commonly known; the generally-entertained notion of it being derived from the accounts of those who had some reason to misrepresent it. It will therefore be worth while to give a somewhat detailed account of it.

The work in which it is described was first published forty-four years after Taliacotius' death, with the title 'De curtorum chirurgia per insitionem libri duo, Venetiis, 1597, folio.' It is divided into two parts, of which the first is chiefly devoted to a disquisition upon the dignity of the nose, lips, and ears, and upon their offices and general construction, and the theory of the operation, which he considers to be exactly analogous to that of grafting upon trees. In the second book he describes the mode of operating, dwelling first at great length upon the necessary number and character of the assistants, the kind of bed to be used, its position with regard to light, &c., and several other minor matters, on all which he speaks like one thoroughly experienced in surgery. In the operation itself he used the following plan:—A part of the skin of the upper arm of the proper size, and bounded by two longitudinal parallel lines, being marked out over the middle of its fore part, was seized between the blades of a very broad pair of nippers. Each blade was about three inches broad, so that it might include the whole length of the portion of skin to be removed, and had a long slit near its edge through which a narrow knife could be passed. The portion of skin of which the new nose was to be formed being raised up by the assistant who held it in the nippers, Taliacotius with a long spear-shaped knife transfixed it through the slits in the blades of the nippers, and cut it through the whole length of the latter from above downwards. Through the aperture thus made, which might be compared to a very broad incision for a seton, a band covered with appropriate medicines was passed, and by being drawn a little every day, the wound was kept open like a seton wound. When all the inflammation had passed away, which was usually in about fourteen days, the flap of skin was cut through at its upper end, and thus a piece bounded by three sides of a parallelogram was raised from the arm, and remained attached to it by nothing but its fourth side or lower end. In this state it was allowed to cicatrize all over, till it acquired the character of a loose process of skin. This being, after some days, completed, and the piece of skin having become firm and hard, it was deemed ready for engrafting. The head therefore being cleanly shaved, a dress and bandage of singular construction, intended for the maintenance of the arm in its due position, were carefully fitted on. Then

these being laid aside, the seat of the old nose was scarified in a triangular space till it had a smooth bleeding surface. A pattern of this surface, being taken on paper, was transferred to the inner surface of the piece of skin on the arm, and a portion of the latter, of the same form and size, was in the same manner made raw. Sutures were placed in corresponding parts of the edges of both these wounds, and they were brought together, the arm being held up with its fore part towards the face, and the palm of the hand upon the head, by the dress and bandage already mentioned. The parts were thus retained in apposition for about twenty days, at the end of which, the surfaces having united, the bandages were taken off, and the portion of skin which was now affixed to both the face and the arm was cut away from the latter. It almost directly became white and cold, but it did not slough, and gradually increased in vascularity and heat. In about fourteen days it was usually firm and secure in its place; and as soon as this was evident, the skin was shaped into the resemblance of a nose by cutting it according to carefully-measured lines and by forming the nostrils in it. A tedious succession of operations were performed upon it before the repair was deemed complete; but at length it is said that in general the restoration was truly admirable. Taliacotius himself however admits that it had, even in the best cases, several defects.

After this account, no one can reasonably doubt that Taliacotius's operation was very often successful. That it should be superseded by the Indian method, as it is called, in which the skin for the new nose is taken from the forehead, is due to the latter being a less tedious and less painful operation, rather than to its being more certain of success. The number of instances in which later attempts to imitate the Taliacotian operation have failed, are due to its having been performed not according to the original method, but according to some of the plans which Taliacotius is erroneously supposed to have followed.

The indecent joke which Butler has made popular in his 'Hudibras' has little foundation. Taliacotius does indeed discuss the propriety of taking the skin for a new nose from the arm of another person; and he concludes that for several reasons it would, if it were possible, be better to do so: but he says he cannot imagine how it would be possible to keep two persons fastened together for the necessary time and with the necessary tranquillity, and that he never heard of the plan being attempted. The tale of the nose falling of when the original proprietor of the skin died, is founded on an absurd story which Van Helmont relates to prove at how great a distance sympathy can act. A gentleman at Brussels, he says, had a new nose made for him by Taliacotius from the arm of a Bolognese porter; and about thirteen months afterwards, as he was walking in Brussels, it suddenly became cold and dropped off, at the very instant at which the porter died at Bologna. Similar stories are told by Campanella, Sir Kenelm Digby, and others; but, as already shown, they are not even fair satires, for Taliacotius never attempted to transfer the skin of one man to the body of another.

(Brambilla, *Storia delle Scoperte fatte dagli Uomini Illustri Italiani*, vol. ii.; Sprengel, *Geschichte der Chirurgie*, Zweiter Theil, p. 195.)

TALIESSIN. [Welsh Language.]

TALIO'NIS, LEX, the law of retaliation; the notion of which is that of a punishment which shall be the same in kind and degree as the injury. This punishment was a part of the Mosaic Law: 'breach for breach, eye for eye, tooth for tooth: as he hath caused a blemish in a man, so shall it be done to him again' (*Levit.*, xxiv. 20). The name 'talio' occurs in the provisions of the Twelve Tables: it is not there defined what it means, but the signification of the term may be collected from other places. The word contains the same element as the word *talis*, 'such,' or 'like.'

TALIPAT or TALIPOT PALM. [Corypha.]

TALISH. [Georgia.]

TALISMA'N an Arabic word, supposed to be derived from the Greek *telesma* (τέλεσμα), is a figure cast in metal or cut in stone, and made with certain superstitious ceremonies, when two planets are in conjunction, or when a certain star is at its culminating point. A talisman thus prepared is supposed to exercise an influence over the bearer, preserving him from disease, rendering him invulnerable in battle, and so forth. They were probably used originally to avert disease, for we find them mentioned in the history of medicine among all ancient nations. The Egyptians made use of figures of sacred animals, such as the ibis and the scarabæus, which they wore generally suspended from their necks. The Arabs and the Turks did the same, when they were idolaters; but after their conversion to Islam, they used sentences from the Koran, taken chiefly from the surah, or chapter, entitled 'The Incantation.' These they wore inscribed on rolls of vellum or paper, enclosed in a silver box, and suspended from their neck; or else engraven upon a signet ring. Military men used similar sentences from the Koran on the hilt or blade of their swords; on their shields, helmets, and other pieces of armour; or woven into their garments. Christian nations even were not exempt from this superstition. In the middle ages, relics of saints, consecrated candles, and rods, rosaries, &c. were employed, and still are, in Spain and in some parts of Italy. The African negroes have their *fetich*, and the American Indians their *medicine*.

(Reinaud, *Monuments Mussulmans du Cabinet du Duc de Blacas*, Paris, 1826.)

TALLAGE is derived, according to Lord Coke, from the law Latin word *tallagium* or *tailagium*, which, as he says, 'cometh of the French word *tailer*, to share or cut out a part, and metaphorically is taken when the king or any other hath a share or part of the value of a man's goods or chattels, or a share or part of the annual revenue of his lands, or puts any charge or burthen upon another: so as *tallagium* is a general word, and doth include all subsidies, taxes, tenths, fifteenths, or other burthens or charge put or set upon any man.' It was generally however confined in its sense to taxes received by the king. The most important statute on the subject is entitled 'De Tallagio non concedendo,' which was passed in the 34th year of Edward III. to quiet the discontent then universal throughout the kingdom. It had arisen among the commons in consequence of the king having taken a tallage of all cities, boroughs, and towns without the assent of parliament. He was embroiled also with the nobles and landowners, from having attempted, unsuccessfully however, to compel all freeholders of land above the value of twenty pounds to contribute either men or money towards his wars in Flanders. The first chapter of the statute is the most important: 'Nullum tallagium vel auxilium per nos, vel hæredes nostros in regno nostro ponatur, seu levetur sine voluntate, et assensu archiepiscoporum, episcoporum, comitum, baronum, militum, burgensium, et aliorum liberorum communium de regno nostro' ('No tallage or aid may be set or levied by us or our heirs in our kingdom without the good will and assent of the archbishops, bishops, counts, barons, knights, burgesses, and other free men of the commons of our kingdom').

These words, as Lord Coke says, are 'plain without any scruple, absolute without any saving;' and, if there could have been perfect reliance on their operation, must have been entirely satisfactory. But the same king had just violated almost the same engagements entered into by himself only six years before. (25 Edward I., c. 5, 6, 7, 'Confirmationes Chartarum;' 2 *Inst.*, 530.) [Subsidy.]

TALLEYRAND-PERIGORD, CHARLES MAURICE DE. This extraordinary man is, and must long, perhaps for ever, continue a mystery. In the éloge of M. de Reinhard, pronounced by M. de Talleyrand, in the Académie des Sciences Morales et Politiques, only three months before his own death, he said: 'A minister for foreign affairs must possess the faculty of appearing open, at the same time that he remains impenetrable; of being in reality reserved, although perfectly frank in his manners.' The precept was his own portrait. His power of concealing his opinions, and his steady adherence to the principle of allowing attacks upon his character to dissipate by time for want of opposition, have had the effect of keeping his contemporaries ignorant of his real character. This taciturnity has frequently occasioned his being subject to imputations which he did not deserve; at times it has beyond a doubt acquired for him a reputation for ability greater than he deserved. It is believed that M. de Talleyrand has left memoirs of his life, or at least of the most important transactions in which he was engaged, but with strict injunctions that they shall not be published until thirty years shall have elapsed from the time of his death. If this be

true, even when the public shall have been put in possession of the contents of these papers, it will only have acquired another statement in addition to those previously in its possession, by the comparison of which it must have to guess at the truth. At present however, while these memoirs continue a sealed book, and scarcely any of M. de Talleyrand's intimate friends have yet contributed their fragments of information, no resource is left to the biographer but by collating his writings, his ostensible share in the politics of his age, and the incidental communications of himself or his acquaintances to estimate as near as he can what probable foundation in reality there is for the accounts of M. de Talleyrand, which have been compiled from what may be called public gossip.

Charles Maurice de Talleyrand-Périgord was born on the 13th of February, 1754, the eldest of three brothers. His family was antient and distinguished; but he was neglected by his parents, and placed at nurse in one of the faubourgs of Paris. The effects of a fall when about a year old rendered him lame for life, and being on this account unfit for the military career, he was obliged to renounce his birthright in favour of his second brother, and enter the church. The contempt and aversion for him, which his parents did not attempt to conceal, impressed a gloomy and taciturn character on the boy. From the charge of his nurse he was transferred to the Collège d'Harcourt, and thence successively to the seminary of St. Sulpice and to the Sorbonne. In all of these institutions he maintained the character of a shy, proud, bookish lad. He showed in after-life a taste for literature, and such an extensive acquaintance with and appreciation of science as sits gracefully on the statesman; and the taste and knowledge must have been acquired at an early age, for his turbulent career after he was fairly launched into busy life left little leisure for that purpose.

By the time he had attained his twentieth year his reputation for talent and his confirmed health appear to have reconciled the vanity of his parents to the necessity of acknowledging him. They introduced him to the society of his equals in rank for the first time at the festivities with which the coronation of Louis XVI. was celebrated (1774), under the title of the Abbé de Périgord. His opinions and tastes, and his temperament, combined to render the clerical profession an object of detestation to him, but he could not escape from it. He availed himself to the full extent of the indulgence with which his age and country regarded the irregularities of the young and noble among the priestly order; but the pride and reserve with which twenty years of undeserved neglect had inspired his confident and strong character served him in part as a moral check. He was a strict observer of the appearances exacted by the conventional morality of society; and this good taste exerted a powerful influence over his whole future career. Thrown back upon himself from the beginning, he had necessarily become an egöist; vigorous both in mind and body, he had a healthy relish of pleasure, and he engaged with eagerness in the pursuits of pleasure; but the enjoyments of the mere voluptuary were insufficient for one of his intellectual character and fastidious tastes.

In 1776 Voltaire visited Paris. M. de Talleyrand was introduced to him, and the two interviews he had with him left such a deep impression that he was accustomed to talk of them with a lively pleasure till the close of his life. Voltaire and Fontenelle were M. de Talleyrand's favourite authors; upon whom he formed his written and still more his conversational style. Conversational talent was in great demand at Paris when he entered the world, and both his love of pleasure and his love of power prompted him to cultivate that which he possessed. That he did so with eminent success the concurrent views of the best judges of his age declare. Excellence of this kind is like excellence in acting: it is impossible to convey an adequate impression of it to posterity. The reporters of flashes of wit and felicitous turns of conversation uniformly communicate to them something of their own inferiority, and vulgarise them in the telling. Again, superior excellence in conversation is an art; the artist is and ought to be judged not by his materials, but by the success with which he uses them. Written *bon mots* are necessarily estimated by their originality, the quantity and quality of thought expressed in them: they are judged as we judge the writings of a poet; whereas the person who introduces them with effect in conversation ought to be judged as we judge the actor, of whom we do not think less because he merely says what the poet has put into his mouth.

The robust and healthy Epicurean who requires the stimulus of intellectual in addition to physical pleasures, is almost inevitably driven to seek the former in the pursuits of ambition. M. de Talleyrand was no exception to the general rule. And the Abbé de Périgord must have displayed, even when he was apparently, when perhaps he believed himself to be, living only for pleasure, qualities which inspired a belief in his business capacity; for in 1780, while yet only in his twenty-sixth year, he was appointed general agent of the clergy of France. He discharged the functions of this important office for eight years. The Gallic church was all along the most independent in its relations to the Papal chair of any church that remained in communion with Rome. It was also a powerful church viewed in its relations to the state, of which it formed an element. Its revenue derived from landed property was large, that derived from other sources perhaps still larger: it had regular assemblies in which it legislated for itself, determined what contributions it ought to pay to the state, and in what proportions its members were to be assessed. Here was a wide field for cultivating experimentally a talent for administration. Nor was this all: the dignified clergy of France took an active part in secular politics. There is a passage in the éloge of M. de Reinhard already alluded to, which seems an echo of the impressions received by M. de Talleyrand in this period of his life:—'I will hazard the assertion that his (M. de Reinhard's) first studies had been an excellent preparation for the diplomatic career. The study of theology in particular had endowed him with a power, and at the same time with a dexterity of ratiocination, which characterise all the documents which have proceeded from his pen. To guard myself against the charge of indulging in paradox, I must here enumerate the names of some of our most distinguished statesmen, all theologians, and all distinguished in history for the success with which they conducted the most important political transactions of their times.' And he follows up the remark with a very respectable list. The general agent of the clergy was their minister of state: and M. de Talleyrand, while he continued to fill the office, was a powerful subject, and occupied a conspicuous place in the eye of the public. In 1788 he was appointed bishop of Autun.

The commencement of his political career, in the strict acceptation of the term, is synchronous with this promotion. An article upon M. de Talleyrand in an early number of the 'Edinburgh Review'—the materials for which were furnished by Dumont,—asserts that he owed his advancement to the see of Autun to a 'Discours sur les Loteries,' which he pronounced in his capacity of agent for the clergy of France, in the Assembly of Notables which met at Versailles, in February, 1787. As bishop of Autun he was a member of the Etats Généraux convoked in May, 1789, which continued to sit as an Assemblée Constituante till it dissolved itself on the 30th of September, 1791. The interval from the meeting of the Notables till the dissolution of the Assembly is an important one in any attempt to solve the problem of M. de Talleyrand's real character.

Previously to the meeting of the States-General, M. de Talleyrand indicated the course he intended to pursue, in a discourse which he addressed to the assembled clergy of his diocese; and in which he advocated the equality of all citizens in the eye of the law, and free discussion. When the three orders, by assenting to meet as one body, had enabled the Assembly to proceed to business, the precise directions given by many of the bailliages to their deputies were found an impediment in the way of practical legislation: M. de Talleyrand moved that they should be entirely disregarded, and carried his motion. A constituent committee was appointed immediately after the capture of the Bastille, and he was the second person nominated a member of it. In this capacity he was called upon to take part in maturing measures which have had a lasting influence upon the progress of affairs in France: the first of these was the re-distribution of the national territory into districts better adapted than the old provinces for the purposes of government; the second was, the organization of a system of finance. In the financial discussions which took place in the committee and Assembly, M. de Talleyrand retained

his dislike of lotteries. He supported all or most of the various loans proposed by Necker; and seconded Mirabeau's exhortations to keep faith with the national creditor. He suggested practical measures with a view to this end, and among others the sale of church lands (he had previously supported the abolition of tithes), reserving however a competent provision for the priesthood, and even improving the condition of the poorer clergy. He also proposed to establish a 'caisse d'amortissement,' as an additional guarantee to the state's creditors. The task of making arrangements for levying the part of the revenue derived from taxes upon persons exercising professions, and upon transfers of property, devolved upon M. de Talleyrand. Connected with his labours in preparing a new territorial division of France, and a new method of collecting the national revenue, was the motion which he made and carried in the Assembly, in August, 1790, to the effect that the king should be intreated to write to his Britannic majesty, to engage the parliament of England to concur with the National Assembly in fixing a natural unit of weights and measures; that, under the auspices of the two nations, an equal number of commissioners from the Academy of Sciences and the Royal Society of London might unite to determine the length of the pendulum in the latitude of 45°, or in any other latitude that might be thought preferable, and to deduce from thence an invariable standard of weights and measures. At the same time that he was taking part with his colleagues of the Constituent Committee in these labours he was charged by them with the important task of preparing the report upon national education, which was read to the Assembly on the 10th, 11th, and 19th of September, 1791. The basis of the system advocated in this report was the secularization of instruction: education was to be the gift of the state, not of the church; the state was to provide instruction for those who proposed to enter the church, exactly as it was to provide instruction for those who proposed to enter any of the other learned professions. Equal stress was laid upon the establishment of elementary schools in every canton; and of a higher class of schools, for the benefit of those who were not destined to embrace a learned profession, in the chief town of every district. Two acts of M. de Talleyrand, which have been much commented upon, appear to be as it were necessary corollaries of the principles avowed in the legislative career we have been passing in review:—his appearance as principal actor in the theatrical celebration of the anniversary of the capture of the Bastille; and his taking upon him the office of consecrating the national clergy.

It is absolutely necessary that some estimate be formed of the conduct and character of M. de Talleyrand while a member of the first National Assembly, as a guide to an appreciation of his far more enigmatical subsequent career. M. de Talleyrand entered the Assembly with the reputation of a dexterous negociator, which he had acquired in his discharge of the office of agent to the clergy. He had then, and he retained in after-life, the character of a self-indulgent man, of a man with a large instinct of self-preservation, but also of a humane man. The disciple of Voltaire and Fontenelle could scarcely be a very zealous Christian, but M. de Talleyrand had always been a respecter of conventional morality: his was precisely that kind of disposition and intellect that supports a church not from belief, but as a useful engine for preserving order in society. M. de Talleyrand, like all the literati of his day, had a theoretical belief in the equality of men; at the same time that with regard to the privileges of the nobility, he was inclined to support them in the same way that he did the authority of the church—as a useful political engine. But involuntarily and perhaps unconsciously M. de Talleyrand was a warmer partisan of the aristocracy than the clergy: he was noble by birth and attached by taste to the habits of a select society, whereas the ecclesiastical character forced upon him against his will had something repulsive to him. In short, M. de Talleyrand saw clearly the rottenness and the absurdity of many of the old institutions of his country: he was willing, desirous, that government should be organized and act in a manner to promote the general happiness; but he had no faith in the capacity of men for self-government; and he had been educated in a church, many of whose members were at that time obliged to reconcile their consciences to remaining in it by adopting the maxim that they were deceiving men for their own good. M. de Talleyrand's idea, and he entertained it in common with a considerable number, was, that the Revolution might be guided, checked, and rendered useful by approximating the constitution of the French to that of the English government. He cared little for the creed of the church, but he wished to preserve the church, and to render it in France what the established church was in England. Hence his care, even while laying hands on the property of the church for the exigencies of the state, to retain an adequate provision for the clergy. hence his anxiety to identify the clergy with the nation. His anxiety to establish a constitution modelled upon that of England was always avowed. His views (the views he adopted, it is not meant to attribute originality to them) regarding territorial divisions and the organization of local government, finance, and education, though overborne for a time in the storm of the Revolution, have revived and been adopted by the Empire, the Restoration, and the present dynasty. The recklessness as to the means by which he attained his ends which he displayed even at this period of his career is no evidence of insincerity, but merely of the want of faith in men, which the treatment he had experienced in early life, and his observation of the society he habitually mixed in, had instilled into him. It was his weakness through life to pride himself in the display of his power of refined mockery, regardless of the enemies it created: he gave vent to his spirit of raillery in actions as well as in words; and thus lent a grotesque colouring to his *coups d'état*, which rendered them more startling than if they had been as prosaic as those of other men. The world is perhaps less startled with the atrocity of passion in a statesman, than with a laughing air which shows his contempt for it. The most startling of his devices is his solemn inauguration of the constitutional monarchy by the religious celebration of the 14th of July. But the love of theatrical presentation and the delusive belief that good may be effected by it is strong in every man at some period of his life. Talleyrand in all likelihood looked forward at that moment to being the founder and future primate of a church which should be to France what the Anglo-Episcopal has been to England. The means to which he was driven to have recourse in order to carry through the installation of the national bishops, undeceived him, and brought back his early disgust for the profession with redoubled force. He not long after resigned his bishopric of Autun, and at the same time renounced his ecclesiastical character.

The history of M. de Talleyrand from the dissolution of the Constituent Assembly, in September, 1791, till the overthrow of the monarchy, on the 10th of August, 1792, would be instructive were it merely as a demonstration of the folly of the self-denying ordinance with which that body terminated its career. Its members were declared ineligible to the next assembly, and also incapable of receiving any appointment from the crown until two years had elapsed from the date of its dissolution. The consequence was, that M. de Talleyrand among others was rendered incapable of any legislative or ministerial office. It was at that time an object with all who desired that the Revolution should have fair play, to preserve peace with England, which, although still ostensibly neutral, was every day presenting additional symptoms of alienation. The court party hated M. de Talleyrand for having taken part frankly with the Revolution; the republicans hated him for his advocacy of a limited monarchy; all parties distrusted him on account of his eternal sneer; but all parties agreed that he was the only man whose talents fitted him for the delicate mission to England. And it was impossible to appoint him to it. He was dispatched however, in January, 1792, without any ostensible diplomatic character, to sound the English ministry, and attempt to commence negociations. His want of an official character allowed the queen to indulge her feelings of personal dislike to the ex-bishop of Autun by turning her back upon him when he was presented at St. James's; and this reception at once ensured his exclusion from general society, and rendered him powerless. After the accession of the Gironde to office, the attempt to ensure at least neutrality on the part of England was renewed: Chauvelin was sent to England as nominal, and along with him Talleyrand as real ambassador. By this time however the French government had become as obnoxious to the general public of England as to the court circles: the torrent was probably

too strong to have been stemmed by Talleyrand, even though he had been in a condition to act directly and in person. He could do nothing, forced as he was to act by the instrumentality of a man too jealous and opiniative to conform honestly to the directions of one whose authority necessarily made him feel himself a mere puppet. Talleyrand's good faith at this period in labouring to preserve peace between England and France, as the only means of rendering a constitutional monarchy possible in the other country, and the steadiness with which he pursued his object, undaunted by the most gross personal insults, are satisfactorily established by the narrative of Dumont.

Talleyrand was at Paris when the events of the 10th of August put an end to the monarchy; and it required all his dexterity to enable him to obtain passports from Danton, to enable him to quit Paris. He fled to England, and having saved little of his property, he was obliged to sell his library there to procure himself the means of support. The English government, jealous of his presence, after some time ordered him to leave the country in twenty-four hours; and proscribed in France, he was obliged, with a dilapidated fortune, to seek refuge in America, when he had almost attained his fortieth year.

Madame de Staël has claimed, and apparently with a good title, the credit of instigating Chenier to demand the recall of M. de Talleyrand after the fall of Robespierre and the termination of the reign of terror. The National Institute was founded about this time, and M. de Talleyrand had in his absence been appointed a member of the class of moral and political science. At the first sitting of this society which he attended he was elected secretary, an office which he held for six months. During this period he read two papers, afterwards published in the 'Mémoires de la Classe des Sciences Morales et Politiques de l'Institut National,' which are justly considered not only as the most able and original of his published writings, but as those which are most indisputably his own. The first of these is entitled 'Essai sur les Avantages à retirer de Colonies Nouvelles dans les Circonstances présentes;' the second, 'Mémoires sur les relations Commerciales des Etats-Unis avec l'Angleterre.' The latter is, properly speaking, a supplement—perhaps rather a 'pièce justificative' appended to the other. The great object of both is to point out the importance of colonies to a country like France, in which the revolutionary fervour, though beginning to burn dim, was still sufficiently powerful to prolong the reign of anarchy and suffering, unless measures were adopted to neutralize it. There can be no mistake as to the views being those of M. de Talleyrand himself. They are such as could only occur to a person entertaining the political opinions he had advocated in the Constituent Assembly, who having been exiled by the 'reign of terror' which decimated his countrymen, was living in a country where a successful revolution had quietly and speedily subsided into a settled form of government; in a country where he felt that 'an Englishman becomes at once a native, and a Frenchman remains for ever a foreigner.' Not satisfied with pointing out in what manner colonies might be rendered powerful assistants in tranquillising France, the essayist entered deeply into the principles of colonization, explaining the advantages to be derived from colonies, and the law by which their economical advantages might be perpetuated even after their political relations with the mother-country had ceased. In his treatment of his subject he evinces a clear and deep insight into the structure of society both in France and America, and just and extensive views in political economy.

It was not however so much the political talent displayed in these essays, as M. de Talleyrand's skill in employing the reviving influence of the *salons* of Paris, that obtained him the appointment of foreign minister under the Directory. Here again he was indebted to Madame de Staël, who assisted him through her influence with Barras. M. de Talleyrand accepted office under this unprincipled government with a perfect knowledge of its character and its weakness. His conviction that a Frenchman could never feel at home in America prompted him to grasp at the first opportunity of returning to his native country: his shattered fortune and taste for expensive luxuries rendered employment necessary for him, and political business was the only lucrative employment for which he was qualified. There is nothing in his life to contradict the belief that he again engaged in politics with a desire to promote what was right and useful as far as he could; but he engaged in them aware that he might be ordered to do what he disapproved of, and prepared to do it, under the plea that his functions were merely ministerial, and that the responsibility rested upon his employers. His position under the Directory was consequently an equivocal one. He was engaged, so long as he occupied it, in intrigues which had for their aim the maintenance of himself in office, even if his employers should be turned out; and he was obliged to do their dirty work. The part which he took in the attempt to extort money, as a private gratification, from the American envoys who arrived in Paris in October, 1797, was probably forced upon him by the directors: had it been his own project, it would have been conceived with more judgment, and the Americans would not have been driven to extremes, for he understood their national character. But allowing himself to be used in such a shabby business betrays a want of self-respect, or a vulgarity of sentiment, or both. He had his reward; for when public indignation was excited by the statements of the American envoys, the minister of foreign affairs was sacrificed to the popular resentment.

Having adopted a profession in which success could only be expected under a settled government, believing a monarchical government to be the only one which could give tranquillity to his country, and anxious with many others to run up a make-shift government out of the best materials that offered, he naturally attached himself to the growing power of Bonaparte. When the future emperor returned from Egypt, M. de Talleyrand had been six months in a private station; though, had he still retained office, he might with equal readiness have conspired to overturn the Directory. Bourrienne is not the best of authorities, but the earlier volumes of the memoirs which pass under his name are less falsified than the later; and an anecdote which he relates of Talleyrand's interview with the first consul, after being reappointed minister of foreign affairs, is so characteristic, that its truth is highly probable:—'M. de Talleyrand, appointed successor to M. de Reinhart at the same time that Cambacérès and Lebrun succeeded Sièyes and Roger Ducas as consuls, was admitted to a private audience by the first consul. The speech which he addressed to Bonaparte was so gratifying to the person to whom it was addressed, and appeared so striking to myself, that the words have remained in my memory:—"Citizen Consul, you have confided to me the department of foreign affairs, and I will justify your confidence; but I must work under no one but yourself. This is not mere arrogance on my part: in order that France be well governed, unity of action is required: you must be first consul, and the first consul must hold in his hand all the main-springs of the political machine—the ministries of the interior, of internal police, of foreign affairs, of war, and the marine. The ministers of these departments must transact business with you alone. The ministries of justice and finance have, without doubt, a powerful influence upon politics; but it is more indirect. The second consul is an able jurist, and the third a master of finance: leave these departments to them; it will amuse them; and you, general, having the entire management of the essential parts of government, may pursue without interruption your noble object, the regeneration of France." These words accorded too closely with the sentiments of Bonaparte to be heard by him otherwise than with pleasure. He said to me, after M. de Talleyrand had taken his leave, "Do you know, Bourrienne, Talleyrand's advice is sound. He is a man of sense." He then added smilingly:—"Talleyrand is a dexterous fellow: he has seen through me. You know I wish to do what he advises; and he is in the right. Lebrun is an honest man, but a mere book-maker; Cambacérès is too much identified with the Revolution: my government must be something entirely new."'

Napoleon and Talleyrand may be said to have understood each other, and that in a sense not discreditable to either. The good sense of both was revolted by the bloodshed and theatrical sentiment, the blended ferocity and coxcombry of the Revolution; both were practical statesmen, men with a taste and talent for administration, not mere constitution-makers. Like most men of action, neither of them could discern to the full extent the advantage an executive government can derive from having the line of

action to a considerable extent prescribed by a constitution; but Talleyrand saw better than Napoleon that the laws which protect subjects by limiting the arbitrary will of the ruler, in turn protect him by teaching them legitimate methods of defending their rights. In another respect they resembled each other—neither was remarkably scrupulous as to the means by which he attained his ends; though this laxity of moral sentiment was kept in check by the natural humanity of both. Their very points of difference were calculated to cement their union. The observant self-centred mind of Talleyrand was lamed by its want of power to set others in motion: it is only through sympathy that the contagious love of action can be conveyed. The impassioned and imaginative soul of Napoleon was made to attach others to him and whirl them along with him; and this power was often too strong for itself: Napoleon, though capable of reflection, was too often hurried away by his instinctive impulses. Each of these men felt that the other was a supplement to himself. Talleyrand really admired and appreciated Napoleon. If he flattered him, it was by the delicate method of confirming him in the opinions and intentions which met his approbation. He dared to tell the First Consul truths which others were afraid to utter; and he ventured to arrest at times the impetuosity of Napoleon, by postponing the fulfilment of his orders until he had time to cool. He opposed, as long as there was any prospect of success, the divorce from Josephine; but his virtue gave way in the business of the Duke d'Enghien, for even though we exculpate him from participation in the execution of that prince, to gratify his master he sanctioned the violation of a neutral territory. This was however the only instance, in so far as Bonaparte is concerned, of his sacrificing the duty of a friend to flattery that can be brought home to him. Napoleon's frequent recurrence, in his conversations at St. Helena, to the subject of Talleyrand's defection, his attempts to solve the question at what time that minister 'began to betray him,' show his appreciation of the services he had received from him.

For a time their alliance continued harmonious, and that was the time of Napoleon's success. The arrangement of the Concordat with the pope was the basis of the future empire, and that negociation was accomplished by Talleyrand. The treaty of Luneville, secularising the ecclesiastical principalities of Germany; the treaty of Amiens, recognising on the part of England the conquests of France, and the new form given to the Continental states by the Revolution; the convention of Lyon, which gave form to the Cisalpine republic; all bear the impress of the peculiar views of M. de Talleyrand. And the minister of foreign affairs was fully aware of his own consequence. In 1801, when obliged by the state of his health to use the waters of Bourbon l'Archambaud, he wrote to Napoleon:—'I regret being at a distance from you, for my devotion to your great plans contributes to their accomplishment.' After the battle of Ulm, Talleyrand addressed to the emperor a plan for diminishing the power of Austria to interfere with the preponderance of France, by uniting Tyrol to the Helvetian republic, and erecting the Venetian territory into an independent republic interposed between the kingdom of Italy and the Austrian territories. He proposed to reconcile Austria to this arrangement by ceding to it the whole of Wallachia, Moldavia, Bessarabia, and the northern part of Bulgaria. The advantages he anticipated from this arrangement were that of removing Austria from interfering in the sphere of French influence without exasperating it, and that of raising in the East a power better able than Turkey to hold a balance with Russia. Napoleon paid no attention to the proposal. After the victory of Austerlitz, Talleyrand again pressed it upon his notice, but equally without effect. No change in the feelings of the emperor and his minister can positively be traced to this event; but we see on the one hand a pertinacious repetition of a favourite proposal, and on the other a silent and rather contemptuous rejection of it. We find at a much later period Napoleon complaining of the pertinacity with which Talleyrand was accustomed to repeat any advice which he considered important; and we find Talleyrand speaking of Napoleon as one who could not be served because he would not listen to advice. And we cannot but see in the difference of opinion just mentioned the commencement of that coolness which induced Talleyrand, on the 9th of August, 1807, to resign the portfolio of foreign affairs and accept the nominal dignity of vice-grand-elector of the empire in addition to the titles of grand-chamberlain and prince of Benevento, which had previously been conferred upon him. An unprecedented career of victory had rendered Napoleon impatient of success; the consciousness of important services had rendered Talleyrand impatient of neglect; and the alienation thus originated was increased and confirmed by the dashing but vulgar soldiers, who formed such an influential part of the emperor's court, and their silly and vulgar wives, who could not pardon M. de Talleyrand his superior refinement, and who had all in turn smarted under his insupportable sarcasm. Napoleon in exile is said to have represented the resignation of M. de Talleyrand as involuntary, and rendered necessary by his stock-jobbing propensities. It is not impossible that the minister may have speculated more deeply in the funds than was altogether proper; but had there been no other reason for his dismissal, Napoleon could, and often did, wink at more flagrant pecuniary delinquencies. M. de Talleyrand, in his character of grand-chamberlain, did the honours of the imperial court at Erfurt; and was on more than one occasion privately consulted by the emperor, who one day said, 'We ought not to have parted.' In 1809 however the ex-minister was so loud and unreserved in his condemnation of the Spanish expedition, that Napoleon, on his return from the Peninsula, deprived him of the office of chamberlain. The last five years of the empire elicited many caustic criticisms from M. de Talleyrand, which were duly carried to the ears of the emperor, who retorted by sallies of abuse which irritated the prince without rendering him less powerful. In 1812 M. de Talleyrand is said to have predicted the overthrow of the empire. In 1813 overtures were made to him with a view to his resuming the portfolio of foreign affairs, but without success. In 1814 he re-appeared on the stage of active life on his own account.

In 1814, as vice-grand-elector of the empire, he was a member of the regency, but was prevented joining it at Blois by the national guard refusing to allow him to quit Paris—not much against his will. When Paris capitulated, the emperor Alexander took up his residence in the house of the prince of Benevento. The words attributed by the Memoirs of Bourrienne to Talleyrand, in his conversations with those in whose hands the fortune of war had for the time placed the fortunes of France, are characteristic, true, and in keeping with his opinions and subsequent conduct:—'There is no other alternative but Napoleon or Louis XVIII. After Napoleon there is no one whose personal qualities would ensure him the support of ten men. A principle is needed to give consistency to the new government, whatever it may be: Louis XVIII. represents a principle. Anything but Napoleon or Louis XVIII. is an intrigue, and no intrigue can be strong enough to support him upon whom it might confer power.' This view lends consistency to the conduct of M. de Talleyrand at the close of Napoleon's career. Their alliance had long been dissolved; they stood confronting each other as separate and independent powers. M. de Talleyrand had advocated a limited monarchy, until the old throne was violently broken up and overturned; he had lent his aid to construct a new monarchy and a new aristocracy out of the fragments of old institutions which the Revolution had left; he saw France again without a government, and, with his principles, he might have consistently taken office under any government, holding, as he did, the opinion that any government is better than none, and that any man may hold office under it provided he take care to do as much good and as little harm as he can. But M. de Talleyrand did more: he exerted the influence he possessed over Alexander to obtain the combination of constitutional forms with the recognition of legitimacy. Louis XVIII. saved appearances by insisting upon being allowed to grant the charter spontaneously, but it was M. de Talleyrand's use of the remains of the revolutionary party that made him feel the necessity of this concession. As minister Talleyrand insisted upon its observance with a precision that rendered him as much an object of annoyance to the courtiers of the Restoration as ever the pedantic Clarendon was to the gay fitters who surrounded Charles II. When he set out for the congress of Vienna, in September, 1814, the court of France is said to have presented the aspect of a school at the commencement of the holidays. The powers who had refused to concede to Napoleon at

the head of a victorious army anything beyond the limits of France in 1792, gave more favourable terms to M. de Talleyrand, the representative of a nation upon which they had just forced a king. He baffled the emperor Alexander, who said angrily, 'Talleyrand conducts himself as if he were minister of Louis XIV.' On the 5th of January, 1815, he signed, with Lord Castlereagh and Prince Metternich, a secret treaty, having previously obliged Prussia to remain contented with a third of Saxony, and Russia to cede a part of the grand-duchy of Warsaw. The imbecility of the Bourbons, by inviting the descent of Napoleon at Frejus, again unsettled everything. M. de Talleyrand dictated the proclamation of Cambray, in which Louis XVIII. confessed the faults committed in 1814, and promised to make reparation. He suggested the more liberal interpretation of the charter, announced from the same place. He obtained an extension of the democratic principle in the constitution of the Chamber of Deputies, recommended the rendering the peerage hereditary, and induced the king, restored for a second time, to institute a cabinet council, of which he was nominated the first president.

The constitutional monarchy, the object of his earlier wishes, was now definitively established; but the part he was destined to perform in it was that of a leader of opposition. In his note of the 21st of September, 1815, he protested, as prime minister, against the new terms which the allies intended to impose upon France. He said they were such conditions as only conquest could warrant. 'There can only be conquest where the war has been carried on against the possessor of the territory, that is, the sovereign; possession and sovereignty being identical. But when war is conducted against a usurper in behalf of the legitimate possessor, there can be no conquest; there is only the recovery of territory. But the high powers have viewed the enterprise of Bonaparte in the light of an act of usurpation, and Louis XVIII. as the real sovereign of France: they have acted in support of the king's rights, and ought to respect them. They contracted this engagement by their declaration of the 13th and their treaty of the 25th of March, to which they admitted Louis XVIII. as an ally against the common enemy. If there can be no conquest from a friend, much more can there be none from an ally.' His argument was fruitless: Louis XVIII. bowed to the dictation of his powerful allies; and M. de Talleyrand resigned office two months before the conclusion of the treaty which narrowed the frontiers of France and amerced her in a heavy contribution. By this step M. de Talleyrand enabled himself to contribute essentially to strengthening the constitutional monarchy, to which, if he had any principle, he had through life preserved his attachment. Had he been a party to the treaty, he must have shared with the elder branch of the Bourbons the odium which attached to all who had taken part in it; and hence thrown the opposition into the hands of the enemies of the constitution. By resigning office, he obtained a voice potential in the deliberations of the opposition; and no English nobleman born and bred to the profession could have discharged more adroitly the functions of an opposition leader. For fourteen years his *salon* was a place of resort for the leaders of the liberal party; in society he aided it by his conversational talents; in the chamber of peers he lent it the weight of his name and experience. He defended the liberty of the press in opposition to the censorship; he supported trial by jury in the case of offences of the press; and he protested against the interference of France in the internal affairs of Spain in 1823. By this line of conduct he was materially instrumental in creating a liberal party within the pale of the constitution; and to the existence of such a party was owing in no small degree the result of the revolution of 1830, in which, though the dynasty was changed, the constitution survived in its most important outlines. That revolution also placed Prince Talleyrand in a condition to realise what had been one of his most earnest wishes at the outset of his political career—an alliance between France and England as constitutional governments. To accomplish this he had laboured strenuously in 1792; to accomplish this was one of the first objects he aimed at when appointed minister for foreign affairs under the consulate: he accomplished it as representative of Louis Philippe.

M. de Talleyrand was appointed ambassador extraordinary and minister plenipotentiary to the court of Great Britain on the 5th of September, 1830; and he held the appointment till the 7th of January, 1835, when he was succeeded by General Sebastiani. During these four years M. de Talleyrand, besides obtaining the recognition of the new order of things in France by the European powers, procured a similar recognition of the independence of Belgium, and concluded the quadruple alliance of England, France, Spain, and Portugal, for the purpose of re-establishing the peace of the Peninsula.

After his return from the mission to England, M. de Talleyrand retired from public life. The only occasion on which he again emerged from domestic retirement was when he appeared at the Académie des Sciences Morales et Politiques, to pronounce the éloge of Count Reinhard, only three months before his own death. He died on the 20th of May, 1838, in the eighty-fourth year of his age.

The object of this sketch has been to present, as far as the very imperfect materials which are attainable would permit, a view of this very extraordinary man undistorted by any partisan feeling either with regard to his person or principles. It must be admitted in favour of M. de Talleyrand that he was warmly beloved by those who were his intimate friends, and by all who were at any time employed under him. It must also be allowed that when his life is contemplated as a whole, it bears the imprint of a unity of purpose animating his efforts throughout. Freedom of thought and expression, the abolition of antiquated and oppressive feudal forms and the most objectionable powers of the church, the promotion of education, the establishment of a national religion, and a constitutional government compounded of popular representation and an hereditary sovereign and aristocracy—these were the objects he proposed for attainment when he entered the arena of politics. He attempted to approach this ideal as far as circumstances would admit at all periods of his long career; and he ended by being instrumental in establishing it. No act of cruelty has been substantiated against him; and the only charges of base subserviency that appear to be satisfactorily proved, are his participation in the attempt to extort a bribe from the American envoys, and in the violation of an independent territory in the seizure of the Duc d'Enghien. His literary was subordinate to his political character. It is difficult to say how much of the writings published in his name were really his own. Latterly, we are informed upon good authority, he was in the habit of explaining his general views on a subject to some one whom he employed to bring this communication into shape; and when the manuscript was presented to him, he modified and retouched it until it met his views, throwing in a good deal of that wit which gave zest to his conversation. The domestic life of M. de Talleyrand has not been alluded to; for almost every statement regarding it is poisoned by the small wit of the coteries of Paris.

The report upon education of 1791; a report to the first consul upon the best means of re-establishing the diplomatic service of France; the essays upon colonization, and the commercial relations of England and America; and the *éloge* of M. de Reinhard—may all be regarded as his own composition. The first is the most commonplace; the other three are master-pieces in their different ways. They bespeak an elegant and accomplished mind, a shrewd insight into character and the structure of society, and a felicitous and graphic power of expression. The wit of M. de Talleyrand was the wit of intellect, not of temperament. It was often full of meaning; always suggestive of thought; most frequently caustic. His reserve, probably constitutional, but heightened by the circumstances of his early life, and cultivated upon principle, was impenetrable. In advanced life it seemed even to have affected his physical appearance. When at rest, but for his glittering eye, it would have been difficult to feel certain that it was not a statue that was placed before you. When his sonorous voice broke upon the ear, it was like a possessing spirit speaking from a graven image. Even in comparatively early life, his power of banishing all expression from his countenance, and the soft and heavy appearance of his features was remarked as contrasting startlingly with the manly energy indicated by his deep powerful voice. Mirabeau in the beginning, Napoleon at the close of the Revolution, threw him into the shade; but he outlasted both. The secret of his power was patience and pertinacity; and his life has the appearance of being preternaturally lengthened out when we recollect

the immense number of widely removed characters and events of which he was the contemporary. It may be said on the one hand that he accomplished nothing which time did not in a manner bring about; but on the other it may be said, with equal plausibility, that scarcely any of the leading events which have occurred in France in his day would have taken the exact shape they assumed had not his hand interfered to give them somewhat of a bias or direction. Next to Napoleon, he certainly is the most extraordinary man the revolutionary period of France has given birth to.

Montholon et Gourgaud; *Eloge de M. le Comte de Reinhard prononcé à l'Académie des Sciences Morales et Politiques*, par M. le Prince de Talleyrand, *dans la Séance du* 3 *Mars*, 1838, Paris, 1838.)

TALLIS, THOMAS, who is considered the patriarch of English cathedral music, was born at about the same period as the famous Italian ecclesiastical composer Palestrina, whose birth took place in the year 1529.

It has been stated, but most probably erroneously, that Tallis was organist to Henry VIII. and his successors. He undoubtedly was a gentleman of the chapel to Edward VI. and Mary; and under Elizabeth the place of organist was added to his other office. He seems to have devoted himself wholly to the duties of the church, for his name does not appear to anything in a secular form. His entire Service, including prayers, responses, Litany, and nearly all of a musical kind comprised in our liturgy, and in use in our cathedrals, appears in Dr. Boyce's Collection, together with an anthem which has long been in high repute with the admirers of severe counterpoint. But for the smaller parts of his Service he was indebted to Peter Marbeck, organist of Windsor, who certainly is entitled to the credit of having added those solemn notes to the suffrages and responses which, under the name of Tallis, are still retained in our choirs, and listened to with reverential pleasure. [Marbeck.]

In 1575 Tallis published, in conjunction with his pupil, Bird (or Byrde), *Cantiones Sacræ*, master-pieces of their kind; and these are rendered the more remarkable from having been protected for twenty-one years by a patent from Queen Elizabeth, the first of the kind that ever was granted. One of these, 'O sacrum convivium,' was adapted by Dean Aldrich to the words 'I call and cry,' and is the above-mentioned anthem, which still continues to be frequently performed in most of our cathedrals. Two more of his anthems are printed in Dr. Arnold's Collection.

Tallis died in 1585, and was buried in the parish church of Greenwich, in the chancel of which Strype, in his continuation of Stowe's *Survey*, tells us he saw a brass plate, on which was engraved, in old English letter, an epitaph, in four stanzas of four lines each, giving a brief history of this renowned composer. The plate was carried away, and most likely sold by weight, by some barbarian, when the church was repaired about a century ago. The verses are to be found in Hawkins, Burney, and most other publications relating to English church music.

TALLOW. [Fat.]

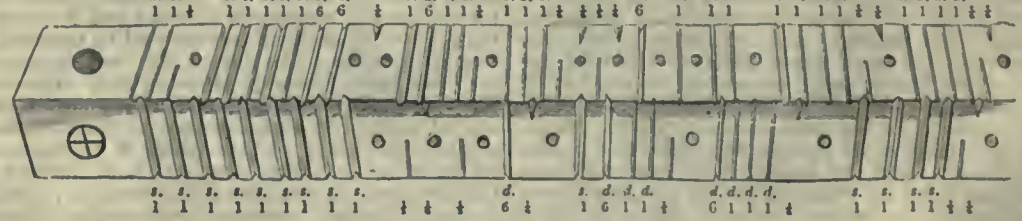
TALLOW, MINERAL or MOUNTAIN. [Hatchetine.]

TALLOW-TREE. [Stillingia.]

TALLY. This word appears to be derived from the French *taille*, or *tailler*, each of which expresses the idea of cutting or notching.

The use of notched sticks or tallies may be traced to a very remote period, and there is reason to believe that they were among the earliest means devised for keeping accounts. Some writers conceive that the Greek symbolum (*σύμβολον*) was in some cases a species of tally, which was used between contracting parties; being broken in two, and one-half given to each. In the 'Pictorial Bible' (note on *Ezek.* xxxvii. 20), much curious information is brought together on the subject of writing or marking with notches upon sticks. The writer of that note refers to the tablets of wood called *axones*, upon which the Athenians inscribed the laws of Solon, and to the practice of the antient Britons, who, he says, 'used to cut their alphabet with a knife upon a stick, which, thus inscribed, was called *Coelbren y Beirdd*, "the billet of signs of the bards," or the Bardic alphabet.' 'And not only,' he continues, 'were the alphabets such, but compositious and memorials were registered in the same manner.' These sticks, he adds, were commonly squared, but were sometimes three-sided; each side, in either case, containing one line of writing. A cut which accompanies the note from which we quote, shows the manner of mounting several such inscribed sticks in a frame, so that they might be read conveniently. Another illustration, of later date, is the clog-almanac described by Dr. Plot, in 1686, as still common in Staffordshire. Such calendars, which had the various days marked by notches of different forms and sizes, were sometimes made small enough to carry in the pocket, and sometimes larger, for hanging up in the house. Similar calendars are said to have been formerly used in Sweden. Perhaps the most curious of the illustrations collected in the note

Fig. 1.



Saxon Reive-Pole used in the Isle of Portland.

Fig. 2.

Exchequer Tally.

referred to is the Saxon Reive-Pole, which either is, or has been down to a recent period, used in the Isle of Portland for collecting the yearly rent paid to the king as lord of the manor. This rent, which amounts to 14*l.* 14*s.* 3*d.*, is collected by the reive, or steward, every Michaelmas; the sum which each person has to pay being scored upon a squared pole, a portion of which is represented in the subjoined cut, with figures to mark the amount indicated by each noteh. 'The black circle at the top,' observes the work from which we quote, 'denotes the parish of Southwell, and that side of the pole contains the account of the tax paid by the parishioners; each person's account being divided from that of his neighbour by the circular indentations between each. In the present instance the first pays 2½*d.*, the second 4*s.* 2*d.*, the next one farthing, and so on.' The other side of the pole which is represented in the cut is appropriated to the parish of Wakem, of which the cross within a circle is the distinctive mark.

The tallies used in the Exchequer (one of which is represented by *fig.* 2) answered the purpose of receipts

as well as simple records of matters of account. They consisted of squared rods of hazel or other wood, upon one side of which was marked, by notches, the sum for which the tally was an acknowledgment; one kind of notch standing for 1000*l.*, another for 100*l.*, another for 20*l.*, and others for 20*s.*, 1*s.*, &c. On two other sides of the tally, opposite to each other, the amount of the sum, the name of the payer, and the date of the transaction, were written by an officer called the writer of the tallies; and, after this was done, the stick was cleft longitudinally in such a manner that each piece retained one of the written sides, and one-half of every notch cut in the tally. One piece was then delivered to the person who had paid in the money, for which it was a receipt or acquittance, while the other was preserved in the Exchequer. Madox observes respecting these rude and primitive records, 'The use of them was very antient; coeval, for aught I know, with the Exchequer itself in England.' They were finally discontinued at the remodelling of the Exchequer in 1834; and it is worthy of recollection that the fire by which the Houses of Parliament were destroyed was supposed to have originated in the over-heating of the flues in which the discarded tallies were being burnt. Clumsy as the contrivance may appear, tallies were effectual in the prevention of forgery, since no ingenuity could produce a false tally which should perfectly correspond with the counter-tally preserved at the Exchequer; and no alteration of the sum expressed by the notches and the inscription could pass undetected when the two parts of the stick were fitted together. A correspondent of the 'Gentleman's Magazine' for November, 1834 (p. 480), states that forgeries were attempted immediately after the discontinuance of tally receipts. The officers of the Exchequer commonly called *tellers* (talliers), as well as several other functionaries, derived their name from the word tally.

Many different kinds of tally are used in gardens and arboretums, to bear either numbers referring to a catalogue, or the names of the plants near which they are placed. Loudon describes several sorts, of wood, metal, earthenware, brick, &c., in his 'Encyclopædia of Gardening.' Wooden tallies are sometimes marked by notches instead of writing or painting; particular forms or combinations of notches being used to represent either Arabic numerals or the Roman letters commonly employed in numeration. Tallies formed of brick-earth, with a recess for containing a printed card, which is sheltered by a piece of glass, have been introduced of late years, and are particularly recommended for use in arboretums. Instead of being stuck in the ground, like tallies of wood and metal, these brick tallies are formed with a broad base, which rests upon its surface.

(*Pictorial Bible*, note on Ezek. xxxvii. 20; Madox's *History of the Exchequer*, *&c.* A popular history of tallies is given in vol. xxiv. of the *Mirror* (pp. 325 and 341), partly condensed from the *Times* newspaper.)

TALMA, FRANÇOIS JOSEPH, an eminent French tragedian, was born in Paris, January 15th, 1763. His father, who was a dentist, went to England shortly after the birth of his son, and practised his profession for some years in London. At nine years of age young Talma returned to France, and was placed in a school at Chaillot, which was kept by Monsieur Lamarguière, a great admirer of the drama, who delighted to discover and encourage a similar taste in any of his pupils. A year after Talma had joined the school he was intrusted with a part in an old tragedy, called 'Simois, Fils de Tamerlane,' which Monsieur Lamarguière had selected for performance by his scholars; and so deeply did the future tragedian enter into the feeling of the character, that he burst into a flood of tears at the recital of the sorrows of the hero, whose brother he represented. At the age of twelve he wrote a little drama, in the composition of which he further developed his knowledge of the stage. He again visited London, and returned a second time to Paris at the latter end of the year 1781, when he commenced the study of logic in the Collège Mazarin. In 1783 he made a *coup d'essai* at the Théâtre de Doyen, in the character of Seide, in the tragedy of 'Mahomet.' A council of friends, appointed by himself, to judge of his performance, pronounced it a failure: 'He had not *le feu sacré*.' Talma deferred to this unfavourable opinion, and quietly resumed the study of his father's profession; but a few years afterwards the very same friends were called upon to reverse their judgment and confess their mistake. On the 21st of November, 1787, he made his début at the Théâtre Français, and in 1789 created a great sensation by his performance of Charles IX. At the commencement of the French Revolution he nearly fell a prey to a severe nervous disorder. On his recovery and the retirement of Larive, Talma became the principal tragic actor. He reformed the costume of the stage, and first played the part of Titus in a Roman toga. During the reign of Napoleon he enjoyed the emperor's friendship; and was no less honoured or esteemed by Louis XVIII. In 1825 he published some 'Reflections' on his favourite art; and on the 11th of June, 1826, appeared for the last time on the stage in the part of Charles VI. During his last illness the audiences of the Théâtre Français every evening called for an official account of the state of his health previously to the commencement of the performances. He died on the 19th of October following, and was buried in the cemetery of Père la Chaise, in presence of an immense crowd. MM. Arnault, Jouy, and Latour pronounced orations over his grave. The Théâtre Français remained closed for three evenings, and the Opéra Comique and Odéon were also closed on the day of his funeral. The actors of the Brussels theatre (of which company he was an associate) wore mourning for him for forty days, and a variety of honours were paid to his memory at the principal theatres throughout France and the Netherlands. Talma is said to have created seventy-one characters, amongst the most popular of which were those of Orestes, Œdipus, Nero, Manlius, Cæsar, Cinna, Augustus, Coriolanus, Hector, Macbeth, Hamlet, Othello, Leicester, Sylla, Regulus, Danville (in 'L'Ecole des Vieillards'), Leonidas, Charles VI., and Henry VIII. He has been accused, remarks one of his biographers, of having spoken the verse of tragedy as though it were prose; but this avoidance of the jingle of rhyme was one of the greatest improvements which he introduced upon the French stage. In person he was about the middle height, square-built, and with a most expressive and noble countenance. His voice was exceedingly fine and powerful, his attitudes dignified and graceful. In private life he was distinguished for his manly frankness, his kind disposition, and unaffected manners. He spoke English perfectly, and was a great admirer of England and her institutions. He was the friend and guest of John Kemble, and was present in Covent Garden Theatre when that great actor took his leave of the stage.

(*Almanach des Spectacles*, 1827; *Biographie Nouvelle des Contemporains; New Monthly Mag.;* Personal Recollections.)

TALMUD. [Hebrew Language.]

TALPA. [Talpidæ.]

TALPASO'REX, M. Lesson's name for a genus of Soricidæ, comprising the *Shrew-mole*. [Vol. xxii., p. 265.]

TA'LPIDÆ, the family of *Moles*.

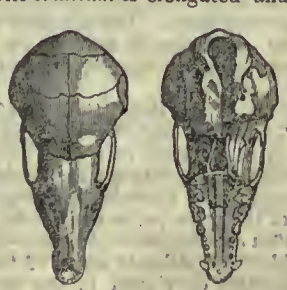
The genus *Talpa* of Linnæus, as it stands in the 12th edition of the *Systema Naturæ*, between the genera *Didelphis* and *Sorex*, comprises two species only, *Talpa Europæa*, the Common Mole, and *Talpa Asiatica*. [Chrysochloris.]

Cuvier places the *Moles*, confining them to the genus *Talpa*, between *Sorex* [Soricidæ] and Condylura.

Mr. Swainson places the genus *Talpa* between *Chrysochloris* and *Centenes*. [Tenrec.]

Organization.

Skeleton.—The *cranium* is elongated and pointed, and



Skull of Mole.

there is a peculiar bone for the support and working of the muzzle. The part which extends from the internal

side of the jaws terminates in three points, the one in the middle larger and more distant from the external edge than the other two. The very short arm attached by means of a long bladebone, and sustained by a vigorous clavicle, carries an extremely wide hand, the palm of which is always turned outwards or backwards. No known

Skeleton of Mole. (De Blainville.) The unchal bone and accessory carpal sabre-shaped bone are here shown.

living form has the compressed phalangeal bones seen in *Glyptodon* except the mole. The second phalanx of the anterior digits or fingers of the mole is the only known living analogue of the similar bone in the hind-foot of *Glyptodon*. The sternum, like that of the birds and bats, has an elevation or crest affording room for the large pectoral muscles. The pelvis and hinder extremities are comparatively feeble. The bones of the pubis are not joined.

This bony framework is set in motion by very powerful muscles. Those of the anterior extremities, the chest, and the neck are most vigorous, and in the cervical ligament a peculiar bone is even formed. The wide hand, which is the great instrument of action, and performs the offices of a pickaxe and shovel, is sharp-edged on its lower margin, and, when clothed with the integuments, the fingers are hardly distinguishable, but the terminating claws project long, strong, flat, and trenchant.

Let us compare for a moment the bats with the moles with reference to their locomotion. Both are insectivorous, but how widely different in their conformation. The bat has to winnow its way through the air: the mole, like the bat, has to react against a given medium, a very different one, certainly; and is endowed with a power of moving through that medium by means of a modification of the locomotive organs beautifully adapted to its density. Instead of the lengthened bones of the forearm that so well assist the bat to make its way with outstretched wing through the air, all in this part of the organization of the mole is short and compact, to enable it to bore through the dense medium where it is to live and move and have its being. The development is all anterior: the fore part of the mole forms an elongated cone; the posterior part is narrow and small, and the whole of its proportions are admirably fitted to assist it, so to speak, in flying through the earth. The long and almost round scapula, the expanded humerus, the enormous power, in short, of the anterior extremities, and the great strength and compactness of the fingers, are all fitted for the digging duty they have to do. Add to this a soft short-cut velvety coat, to which no particle of soil ever adheres, and you have the perfection of organization for rapid progress through the ground.

Nor is it void of interest to observe the niceties of adaptation according to circumstances. The CHRYSOCHLORIS (*Talpa aurea* of the older authors) is an inhabitant of Africa, and burrows in sand. This medium required a modification of organization different from that required to permeate the heavier soils, and we have it. Though some of the bones are strong, the general strength is less than in the common Mole. The principal burrowing instrument is the great double anterior toe (ring-finger), and there is an enormous development of the pisiform bone.

In the museum of the Royal College of Surgeons, in London, No. 282 G, of the *Physiological Series*, shows the anterior half of the body of a Mole (*Talpa Europæa*, Linn.), in which the diaphragm and principal muscles of the right extremity are dissected and exposed, as illustrative of one of the principal structures for burrowing.

Nervous System and Senses.—(*Touch.*)—The muzzle of the mole is evidently a delicate organ of touch, and that sense is considerably developed in the large and broad hands and feet. Neither is the tail without a considerable share of sensation, to give notice to the animal of the approach of any attack from behind.

Taste and Smell.—The gustatory and olfactory nerves, especially the latter, appear to be very sensitive.

Sight.—Almost rudimentary. The little eye is so hidden in the fur, that its very existence was for a long time denied. It appears to be designed for operating only as a warning to the animal on its emerging into the light; and indeed more acute vision would only have been an incumbrance. No. 1772 (*Mus. Coll. Reg. Chir., Phys. Series*) is the anterior part of a mole (*Talpa Europæa*, Linn.), showing the minute circular palpebral orifices defended by the short thick fur.

Hearing.—But if the sight be imperfect, the sense of hearing is very highly developed, and the tympanum very large, though there is no external ear, or rather, no projecting concha. No. 1608, in the department of the museum of the Royal College of Surgeons above referred to, exhibits the anterior part of a mole (*Talpa Europæa*, Linn.), from which the hair has been removed, to show the external orifices of the ears and eyes, in both of which bristles are placed. No. 1609 is also the anterior part of the same animal with the fur left on, showing the entrance to the meatus auditorius externus unprovided with a projecting concha, or external ear, which would be an impediment in the act of burrowing, and an unnecessary appendage: the meatus is defended in this animal, which lives habitually in the soil, by the smallness of the external opening. John Hunter, in his *Manuscript Catalogue*, introductory of this part of the series, observes that an external concha is not to be found in many animals whose life is principally led underground, such as the mole; and perhaps because the earth assists considerably in vibration.

There is nothing that calls for any particular notice in the *Digestive System* of the Mole. The alimentary canal is short, simple, without a cæcum. The voracity of the mole corresponds with the activity and rapidity of its digestive powers.

Generative and Urinary Systems.—No. 2505 of the Physiological Series in *Mus. Coll. Reg. Chir.* exhibits a mole with the abdomen laid open to show the testes as they appear in winter. They are lodged in large cremasteric pouches in the perinæal region, making no projection externally. The right testis is drawn into the abdomen by the side of the bladder, and its posterior extremity may be seen attached to the inverted cremaster: the left testis has its anterior extremity projecting into the abdominal cavity. The prostatic glands, which consist of an aggregate of cæcal tubes, are just visible behind the bladder. No. 2506 is a mole killed in February, and prepared to show the increased size of the testes, and the commencing sexual development of the prostatic cæca. No. 2507 is a mole killed in the beginning of March, and prepared to show a further increase of the testes and accessory prostatic glands: the latter have now advanced forwards on each side of the urinary bladder, so as to encompass its neck: the left testis has been drawn back into the abdomen, and its attachment to the inverted cremasteric pouch displayed. No. 2508 is a mole killed about the latter end of March, and dissected to show the complete development of the testes and prostatic glands. The long penis and its two crura, surrounded by the erectores muscles, are also shown. No. 2509 is a mole which was killed in autumn, prepared to show the collapsed state of the testes, and the atrophied condition of the pro-

static glands; but the testes in this case had not yet returned to the small size which they exhibit in winter. No. 2510 is a preparation showing a side view of the male organs of generation; and No. 2511 exhibits the male organs of *Chrysochloris capensis*. (*Cat.*, vol. iv.)

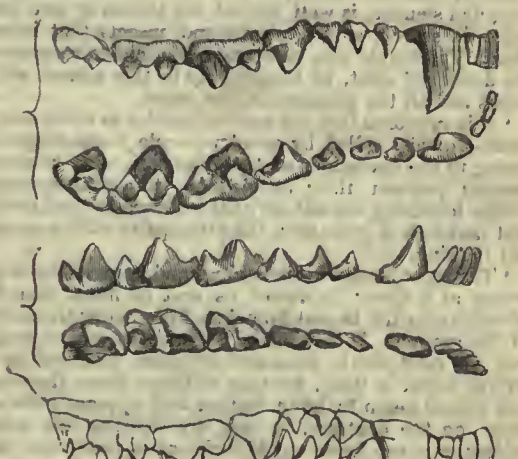
The increase and decrease of the testes in BIRDS and FROGS are well shown in preparations in the same noble museum; the first in Nos. 2457 to 2462 (both inclusive), the second in Nos. 2412 and 2411. John Hunter, in his 'Animal Œconomy,' observes that these seasonal or periodical changes are common to all animals which have their seasons of copulation. 'In the buck,' says that great physiologist, 'we find the testicles are reduced to a very small size in winter; and in the land-mouse, mole, &c. this diminution is still more remarkable. Animals, on the contrary, who are not in a state of nature, have no such change take place in their testicles; and not being much affected by seasons, are consequently always in good condition, or in a state to which other animals that are left to themselves can only attain in the warmer season. Therefore in man, who is in the state we have last described, the testicles are nearly of the same size in winter as in summer; and nearly, though not exactly, the same thing may be observed in the horse, ram, &c., these animals having their seasons in a certain degree. The variation above taken notice of is not confined to the testicles, but also extends to the parts which are connected with them: for in those animals that have their seasons for propagation the most distinctly marked, as the land-mouse, mole, &c., the vesiculæ are hardly discernible in the winter; but in the spring they are very large, varying in size in a manner similar to the testicle. It may however be alleged that the change in these bags might naturally be supposed to take place, even admitting them to be seminal reservoirs; but what happens in the prostate gland, which has never been supposed to contain semen, will take off the force of this objection; since in all animals which have such a gland, and which have their season for propagation, it undergoes a limited change. In the mole the prostate gland is hardly discernible, but in the spring becomes very large, and is filled with mucus.'

No. 2807 exhibits the posterior part of a mole (*Talpa Europæa*), with the female generative and urinary organs exposed. The uterus is turned to the right side, principally to display the course and attachments of the ovarian and uterine ligaments. The ovarian ligament commences anterior and external to the kidney, and carries forward with it a fold of the peritoneum as it advances to the ovarium. The uterine ligament, or ligamentum rotundum, is continued from the extremity of the cornu uteri, and runs along the posterior edge of the preceding fold to the part corresponding to the abdominal ring in the male, where it expands upon the fascia. The left ovary and oviduct, the cornua and corpus uteri, are also exhibited. The ovary is tuberculate, and inclosed in an almost complete peritoneal capsule. The oviduct is attached to this capsule, and pursues a wavy course to the horn of the uterus. No. 2808 displays the female organs of a mole *in situ*, the ventral parietes of the abdomen and chylopoietic viscera having been removed. The cornua uteri, cylindrical tubes, describe three abrupt curves before joining the corpus uteri, with which they form almost a right angle. The body of the uterus is continued without any constriction or interruption into the vagina: the whole canal is somewhat flattened, and is disposed in two or three vertical curves or folds before it leaves the abdomen. No. 2809 is also the posterior half of a mole, with the female organs similarly displayed, but minutely injected. The cornua uteri are divaricated, to display the extent of the broad ligaments. No. 2810 is a section of a mole, in which the left ovary, oviduct, and uterine horn, and the left side of the uterus and vagina, have been removed, but exposing the remainder of the generative apparatus *in situ*, and exhibiting its relative position to the urinary bladder, the rectum, and the pelvis. The contracted area of the uterine cavity, the absence of any os tincæ dividing it from the vagina, and the distinct muscular and internal membranous tunics of the flattened tortuous utero-vaginal canal, are clearly displayed. A bristle is inserted into the right horn of the uterus, and another is passed through the clitoris, which is perforated by the urethra. 'Thus,' continues Professor Owen, the author of the catalogue, 'the urethra, vagina, and rectum open by distinct orifices on the exterior of the body, and all three canals lie anterior to the pubic bones, and consequently outside the pelvis.'

No. 1224 of the same series exhibits the kidney of a mole injected and longitudinally divided. The uninjected tubuli may be plainly seen extending through the cortical substance, as is shown in the injections of the kidney of the horse, Nos. 1209 to 1214, both inclusive. (*Cat.*, vol. ii.)

Generic Character.—Body stout and thick, furry; head elongated, pointed; muzzle cartilaginous, strengthened by the snout-bone; eyes very small; no external ears; anterior feet short and wide, with five united toes armed with trenchant nails proper for digging; posterior feet with five toes also, but weak; tail short.

Dental Formula:—Incisors $\frac{6}{8}$; canines $\frac{1-1}{0}$; molars $\frac{7-7}{7-7}$: = 44.



Teeth of Mole, considerably enlarged. (F. Cuv.)

Example, *Talpa Europæa*, the common mole.

This well-known animal, so familiar to all that it would be a needless waste of space to describe it, is *La Taupe* of the French, *Talpa* of the antient and modern Italians, *Topo* of the Spanish, *Toupeira* of the Portuguese, *Maulwerf* of the Germans, *Mol* of the Dutch, *Mulvad* and *Surk* of the Swedes, *Muldvarp* of the Danes; *Mole*, *Mole-warp*, *Moldwarp*, and *Want* of the modern British; and *Gwadd* and *Twrch daear* of the antient British.

Habits, Food, Reproduction, &c.—'A subterraneous life,' says Pennant, speaking of the mole, 'being allotted to it, the seeming defects of several of its parts vanish; which, instead of appearing maimed or unfinished, exhibit a most striking proof of the fitness of their contrivance. The breadth, strength, and shortness of the fore-feet, which are inclined sideways, answer the use as well as the form of hands, to scoop out the earth, to form its habitation, or to pursue its prey. Had they been longer, the falling in of the earth would have prevented the quick repetition of its strokes in working, or have impeded its course; the oblique position of the fore-feet has also this advantage, that it flings all the loose soil behind the animal.

'The form of the body is not less admirably contrived for its way of life: the fore-part is thick and very muscular, giving great strength to the action of the fore-part, enabling it to dig its way with great force and rapidity, either to pursue its prey or elude the search of the most active enemy. The form of its hind parts, which are small and taper, enables it to pass with great facility through the earth that the fore-feet had flung behind; for had each part of the body been of equal thickness, its flight would have been impeded and its security precarious.

'The skin is most excessively compact, and so tough as not to be cut but by a very sharp knife; the hair is very short and close-set, and softer than the finest silk; the usual colour is black, not but that there are instances of these animals being spotted, and a cream-coloured breed is sometimes found in my lands near Downing.'

'The smallness of the eyes (which gave occasion to the antients to deny it the sense of sight*) is to this animal a peculiar happiness; a small degree of vision is sufficient for an animal ever destined to live underground; had these organs been larger, they would have been perpetually liable to injuries by the earth falling into them; but nature, to prevent that inconvenience, hath not only made them very small, but also covered them very closely with fur. Anatomists mention (besides these) a third very wonderful contrivance for their security, and inform us that each eye is furnished with a certain muscle, by which the animal has the power of withdrawing or exerting them, according to its exigencies.

'To make amends for the dimness of its sight, the mole is amply recompensed by the great perfection of two other senses, those of hearing and of smelling: the first gives it notice of the most distant approach of danger; the other, which is equally exquisite, directs it in the midst of darkness to its food: the nose also, being very long and slender, is well formed for thrusting into small holes in search of the worms and insects that inhabit them. These gifts may with reason be said to compensate the defect of sight, as they supply in this animal all its wants and all the purposes of that sense.

'It is supposed that the verdant circles so often seen in grass-grounds, called by country-people *fairy rings*, are owing to the operations of these animals, who, at certain seasons perform their burrowings by circumgyrations, which, loosening the soil, give the surface a greater fertility and rankness of grass than the other parts within or without the ring.

'The mole breeds in the spring, and brings four or five young at a time: it makes its nest of moss, and that always under the largest hillock, a little below the surface of the ground. It is observed to be most active, and to cast up most earth, immediately before rain, and in the winter before a thaw, because at those times the worms and insects begin to be in motion and approach the surface: on the contrary, in very dry weather this animal seldom or never forms any hillocks, as it penetrates deep after its prey, which at such seasons retires far into the ground. During summer it runs in search of snails and worms in the night time among the grass, which makes it the prey of owls. The mole shows great art in skinning a worm, which it always does before it eats it; stripping the skin from end to end, and squeezing out the contents of the body.'

Thus far Pennant: but the most diligent and instructive historian of the mole is Henri Le Court, who, flying from the terrors that came in the train of the French revolution, buried himself in the country, and, from the attendant on a court, became the biographer of this humble animal. The discoveries of this indefatigable observer have been laid before the public in the work of De Vaux (1803), and a summary of them by Geoffroy St. Hilaire, in the *Cours d'Histoire Naturelle des Mammifères*. The latter visited Le Court for the purpose of testing his observations, and appears to have been charmed by the facility and ingenuity with which Le Court traced and demonstrated the subterranean labours of this obscure worker in the dark.

One of the experiments which Le Court made afforded ample proof of the rapidity with which the mole will travel along its passages. He watched his opportunity, and when the mole was out on its feed at one of the most distant points from its sanctuary or fortress, to which point the mole's high road leads, Le Court placed along the course of that road between the mole and the fortress several little camp-colours, so to speak, the staff of each being a straw and the flag a bit of paper, at certain distances, the straws penetrating down into the passage. Near the end of the subterraneous road he inserted a horn, the mouth-piece of which stood out of the ground. When all was ready, Le Court blew a blast loud enough to fright all the moles within hearing from their propriety, and the little gentleman in velvet, whose presence at the spot he had well ascertained, was affected accordingly. Down went the little flags in succession with an astonishing celerity, as the horrified mole, rushing along towards his sanctuary, came in contact with the flag-straws; and such mettle had terror put into the animal's heels, that the spectators affirmed that its swiftness was equal to the speed of a horse at a good round trot.

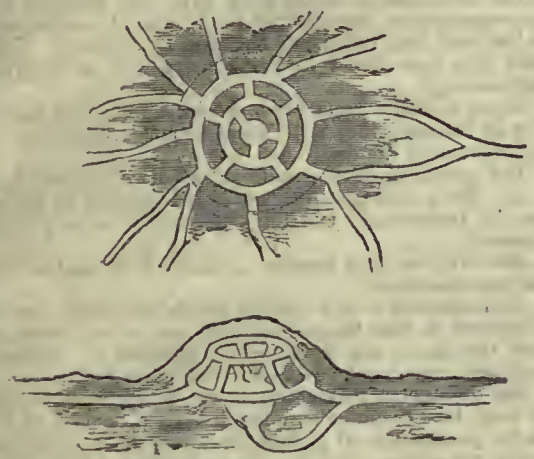
This experiment was perfectly satisfactory as to the auditory and travelling powers of the mole; but another made by Le Court equally proved that the amount of vision possessed by the animal is amply sufficient for its wants, and that, with all the imperfections of this sense, its sight warns it of danger. Le Court took a spare water-pipe or gutter open at both ends. Into this pipe he introduced several moles, successively. Geoffroy St. Hilaire stood by to watch the result, at the farther end of the tube. As long as the spectators stood motionless, the introduced mole made the best of his way through the pipe and escaped; but if they moved, or even raised a finger, the mole stopped and then retreated. Several repetitions of the experiment produced the same results.

But we must describe the mole's domain. The principal point is the habitation, or, as it has been termed, the fortress, and is constructed under a considerable hillock raised in some secure place, often at the root of a tree, under a bank, or any shelter that offers protection. The fortress is domed by a cement, so to speak, of earth which has been beaten and compressed by the architect into a compact and solid state. Within, a circular gallery is formed at the base, and communicates with a smaller upper gallery by means of five passages, which are nearly at equal distances. Within the lower and under the upper of these galleries is the chamber or dormitory, which has access to the upper gallery by three similar passages. From this habitation, we should here observe, the high road by which the proprietor reaches the opposite end of the encampment extends, and the various galleries or excavations open into this road, which the mole is continually carrying out and extending in its search for food, and which has been termed its hunting-ground. But to return to the chamber. From it another road extends, the direction of which is downward at first, and that for several inches, when it again rises to open into the high road of the territory. Some eight or nine other passages open out from the external circular gallery, but the orifices of these never come opposite to the passages which connect the external gallery with the internal and upper gallery. The extent of these passages is greater or less, according to circumstances, and they each return by an irregular and semicircular route, opening at various distances from the habitation into the high road, which differs considerably from all the other passages and excavations, both in construction and with regard to the use to which it is applied. From the habitation this road is carried out nearly in a straight line and forms the main passage of communication between the habitation, the different portions of the encampment, and the alleys leading to the hunting-ground which open into it on each side. In diameter it exceeds the body of a mole, but its size will not admit of two moles passing each other. The walls, from the reiterated pressure of the mole's sides against them, become smooth and compact, and its course is remarkable for the comparative absence of mole-hills, which are frequent in connection with the alleys and quarries, as they have been termed, in constructing which the earth is removed out of the way to the surface. Sometimes a mole will lay out a second or even a third road in order to the extension of its operations. Sometimes several individuals use one road in common, though they never trespass on each other's hunting-grounds. In the event of common usage, if two moles should happen to meet, one must retreat into the nearest alley, unless both should be pugnacious, in which case, the weakest is often slain. In forming this tunnel, the mole's instinct supplies the place of science, for he drives it at a greater or less depth, according to the quality of the soil, or concurrent circumstances. When there is nothing superincumbent threatening a disturbance of its security, it is often excavated at a depth of some four or five inches; but if it is carried under a road or a stream, a foot and a half of earth, sometimes more, is left above it. Thus does the little animal carry on the subterraneous works necessary for his support, travelling, and comfort; and *his* tunnels never fall in.

The alleys opening out from the sides of the high road have generally a somewhat downward inclination from their commencement towards their end. It has been observed that when, on opening one of these alleys, a plen-

* 'Aut *oculis capti* fodere cubilia talpæ.' Virg., *Georg.* i., 183.

tiful supply of food is found, the mole proceeds to work out branch alleys from its termination, up-heaving new mole-hills as it advances in quest of prey: should however the soil be barren of the means of existence, the animal commences another alley at a different part of the high road. The quality and humidity of the soil, which regulate the abundance of earth-worms, determine the greater or less depth of the alleys.



Habitation or fortress of Mole.

The main road being the highway of communication to its different hunting-grounds, it is necessarily passed through regularly in the course of the day, and it is in this road that the mole-catcher sets his traps or practices his devices to intercept the animal between its habitation and the alley where it is carrying on its labours. Some mole-catchers will tell you that the hours when the moles move are nine and four, and others that, near the coast, their movements are influenced by the tides; to which statements the hearer is at liberty to give as much credence as he chooses. Besides the various traps which are set for them, there is, or very lately was, a man who travelled the country with a dog and destroyed them without any trap at all, by the following process: Taking his station at the proper time and place, attended by his dog, and armed with a spear or spud, he waits till the dog indicates the presence of the mole, and then spears or spuds the animal out as it moves in its run. Pointers will stop at moles as steadily as at game, when the latter are straying on the surface.

Besides the excavations already noticed, the moles pursue another mode of hunting in light loose soils, newly sown, when gentle rains have led the earth-worms towards the surface, along which they follow the worms up, rapidly digging a shallow trench in the superficial layer of the soil. The female, when with young, is said to be principally addicted to this easier method of subsistence.

All the animal passions are strong in the mole, and it is a most voracious animal. It has been supposed that it was a vegetable as well as an animal feeder, and, as a proof of the former, the fragments of roots, &c., found in its stomach have been appealed to; but there can be no doubt that these vegetable matters had been conveyed into the stomach with the earth-worms (their favourite food) and the larvæ of insects. The structure of its teeth indicates that its food should be animal, and indeed mice, lizards, frogs, and even birds have been known to fall victims to its voracity; but it eschews toads even when pressed by hunger, deterred probably by the acrid secretion of their skin. [Frogs, vol. x., p. 493.] All doubts as to the carnivorous nature of the mole have however been removed by the experiments of M. Flourens, who found that moles restricted to carrots, turnips, various kinds of herbs, and vegetable substances which were abundantly supplied to them, died of hunger. The mole indeed appears to require much nourishment, and a short fast proves fatal to it.

We must not omit to notice the provision of this animal to secure a supply of water, for its voracity makes it a great drinker. If a pond or ditch be at hand in those cases where many moles use the same common highway, a run is always formed to the reservoir: when it is too distant, the animal sinks little wells in the shape of deep perpendicular shafts, which hold water. These wells have sometimes been seen brim-full.

During the season of love, at which time bloody battles are fought between the males, the male pursues the female with ardour through numerous divaricating superficial runs wrought out with great rapidity, termed 'coupling runs' and 'rutting angles' by our mole-catchers, and 'traces d'amour' by the French. The sexual attachment appears to be very strong in the moles. Le Court often found a female taken in his trap, and a male lying dead close to her. The period of gestation is two months at least, and the young are generally produced in April, but have been found from that month to August. From four to five is the general number, though from three to six have been recorded, and in one case seven* in one nest. The nest is distinct, usually distant from the habitation, and not always crowned with a hillock; but when a hillock exists, it is much larger than an ordinary mole-hill. It is constructed by enlarging and excavating the point where three or four passages intersect each other; and the bed of the nest is formed of a mass of young grass, root-fibres, and herbage. In one case, Geoffroy St. Hilaire and Le Court counted two hundred and four young wheat-blades.

In the Museum of the Royal College of Surgeons in London, No. 3573 of the Physiological Series is the posterior half of a pregnant mole, with the uterus and three fœtuses, each about half an inch in length, exposed *in situ:* the ovarium is contained in a thin and transparent peritoneal capsule, around which the oviduct may be observed passing in the form of an opaque, white, narrow band: the uterine dilatation next the left ovarium remains open, and the fœtus is exposed inclosed in its membranes; the other uterine dilatations are left entire; they resemble blind pouches developed from one side of the uterine tube. No. 3574 is the posterior extremity of the trunk of a pregnant mole, with the uterus and five fœtuses displayed *in situ;* one of the dilated chambers of the left uterine horn is laid open, and the fœtus is exposed with its membranes. The placenta is a spongy, vascular substance, in the form of an oblong flat band, with its long axis parallel to that of the fœtus. One of the uterine chambers, with the corresponding chorionic sac, is laid open in the right horn of the uterus, and the fœtus is displaced. No. 3575 presents the female organs of a pregnant mole with four fœtuses, each one inch and a quarter in length; one of these is exposed *in situ* in the uterine sac, two others hang suspended by their membranes and the placentæ from the parietes of the uterus: in the lower of these embryos the fœtal placenta is partly separated from the maternal portion, showing the fine areolar structure of the latter, which receives the fœtal placentary filaments: the maternal placenta is minutely injected, but no portion of injection has passed into those fœtal filaments which are here exposed; the capacity of the chorion is very little larger than the fœtus which it contains. In the embryo which has been displaced from the chorionic sac, the short umbilical cord, and the characteristic form of the short and strong fossorial anterior extremities, may be discerned: the external apertures of the eyes and ears are completely closed. The canal leading from the uterine horns to the external opening of the vagina is laid open, showing the absence of any os tincæ dividing the uterus from the vagina: a bristle is passed into the urethra, which is continued through the clitoris. The author of the catalogue (Professor Owen) observes that the peculiar position of the vagina of the mole, on the outside of the pelvis, is well displayed in No. 2810, above noticed, and that by this modification the contracted pelvis offers no impediment to parturition. (*Cat.*)

Heavy charges have been brought against the mole by agriculturists and horticulturists, and the more grave accusation of being ancillary to the destruction of dykes has been in some instances proved upon it. Mr. Bell, in his interesting *History of British Quadrupeds*, sums up the evidence against it and in its favour thus:—'In order to arrive at a true solution of the question, it is necessary to divest our minds as well of the prepossessions of the naturalist as of the prejudices of the agriculturist; for we shall probably find, as in most other cases, that the truth lies between the two extremes.' According to its accusers,

* Loudon's 'Magazine of Nat. Hist.,' vol. viii.

there is no portion of its labours, no peculiarity of its habits, no function of its organization, that is not the means or the cause of ravage and devastation to our cultivated grounds. The soil, say they, is rendered dry and sterile by its subterraneau roads; the crops are killed by the exposure or the destruction of the roots; the plants themselves are overthrown by the construction of the mole-hills, or they perish from their roots being eaten, or they are dug up and scattered by the superficial furrows which the animal ploughs up either in search of food or in pursuit of its mate; large quantities of young corn too are carried off by it to form its nest; and, finally, its abandoned fortress becomes the resort of the field-mouse and other noxious animals. Thus the field and the meadow, the garden and the plantation, are alike the scenes of its ravages; and De Vaux calculates that the loss which it occasions to the spring corn alone may be calculated at one-eighth of the whole produce. Then, on the other hand, these prejudiced judges allow nothing for the benefit which arises from the destruction of innumerable worms, and of insects both in the larva and perfect state: this advantage is in fact denied by De Vaux, who declares that the mole feeds only on the most harmless of those animals, the earth-worm, and that it refuses those which are injurious to mankind. Its more benevolent advocates, on the other hand, contend not only that the injury which it perpetrates is slight, but that it is more than counterbalanced by the benefit which it produces by turning up and lightening the soil, and especially by its immense destruction of earth-worms and many other noxious animals which inhabit the superficial layer of the ground, and occasion great injury to the roots of grass, corn, and many other plants. If we examine the real nature and degree of its injuries on the one side, and its utility on the other, we shall probably find that both parties are erroneous. The fact of its devastations cannot be denied, it is only in the degree and extent of them that the estimation is incorrect; and whilst its utility in clearing the ground of worms and similar causes of injury must also be allowed, it can scarcely be sustained that the lightening of the soil by the turning up of its hillocks is, at most, more than a very equivocal source of advantage.'

Thus we see that 'much may be said on both sides.' We have heard advocates for the mole declare that in great sheep-walks whence they have been rooted out, the whole character of the feed has been altered, and the exterminators have been obliged to introduce them again, and we have heard such stories denied. Too much stress however may be laid on its services as a destroyer of the earth-worm; for it may be well doubted whether it aids the agriculturist by the destruction of an animal that does so much for the soil. [LUMBRICUS, vol. xiv., p. 196.]

Whatever may be the merits of the case, the persecution of these animals in cultivated countries amounts almost to a war of extermination. The numbers annually slaughtered are enormous. Mr. Bell states that Mr. Jackson, a very intelligent mole-catcher, who had followed the craft for thirty-five years, had destroyed from forty to fifty thousand. But all mole-exterminators must yield to Le Court, who, in no large district, took, in five months, six thousand of them.

Moles are good swimmers, and their bite is very sharp: when their blood is up, their ferocity is great, and they keep their hold like a bull-dog.

As to the question whether the species under consideration is the *aspalax* (ἀσπάλαξ) of Aristotle, who describes his animal as blind, see the article MURIDÆ, vol. xv., p. 516.

Geographical Distribution.—The common mole is found throughout the greater part of the continent of Europe and its larger islands. In Greece it is said to be comparatively rare. We are overrun with it in most parts of England and Wales, but it does not appear to have been found in the northern extremity of Scotland, though it is frequent enough in the south. There is no record of its having been seen in the Orkney Isles, Zetland, or Ireland.

The Prince of Musignano has well figured, in his excellent work, *Iconografia della Fauna Italica*, the species under consideration and the *Talpa cæca*, which may be the *Aspalax* of Aristotle. In this last species the middle incisive teeth are longer than the rest; in the common mole they are all equal, and De Vaux states that there is some difference, though not great, in the habits and architecture of the two species. Mr. Bell suggests that as both species are inhabitants of Europe, the original trivial name *Europæa* should be dropped, and Brisson's name, *vulgaris*, be adopted for the common species.

For Dr. Richardson's account of the true moles brought from America, see the article SORECIDÆ, vol. xxii., p. 265.

Fossil Moles.

The fossil remains of the mole have been found in the bone-caverns; as, for example, in the cave at Köstritz and at Paviland (see Buckland, *Reliquiæ Diluvianæ*). They have also been found in the bone-caverns in Belgium (Schmerling).

Bones of moles have been obtained from the brown clay of Norfolk: they were, we understand, first taken for the remains of lizards.

The questions which arise upon this discovery are:—

1st. Were they true fossils of that formation or subsequently introduced? and this their condition might determine.

2nd. Are the fossil remains identical with the bones of the common mole?

An inspection of the remains themselves might convey a solution of both these questions, and we are informed that the fossils are, through the kindness of Professor Sedgwick, about to be sent up to Professor Owen.

But throughout this inquiry it will be necessary to bear in mind that though this quadruped is a denizen of the earth, performing all its functions, with little exception, below the surface, and though we might for that reason be led to expect the frequent occurrence of its remains in a fossil state, *true* fossil bones of the mole have not hitherto been described. The danger to be guarded against with regard to those specimens found in the newer and superficial strata is that a burrowing animal may have penetrated into those fossiliferous beds subsequently to their formation and the deposit of their organized contents. We therefore look forward to Professor Owen's opinion upon the *condition* of these remains and their specific distinction with much interest.

TALUS, or TALUT, probably from 'taglio,' Ital., a cut, is a term used chiefly by writers on fortification, in speaking of a rampart or parapet, to signify a surface which is inclined to the horizon. Thus the upper surface of a parapet is called the superior talus or slope; and that surface of a rampart or parapet which is towards the country, or towards the town, is called the exterior, or the interior, talus of the work (*fig.* 2, BASTION).

The superior talus of a parapet is usually formed in a plane which, if produced towards the country, would nearly meet the top of the countersearp before it, in order that the defenders of the rampart may be able to fire into the covered way in the event of the latter being occupied by the enemy, their muskets being laid upon that slope. The exterior or the interior talus of any work of earth usually forms, with the horizon, an angle of 45 degrees; such being the inclination at which the surface of earth, of medium tenacity, will stand unsupported.

TAMAN, a peninsula, or rather a delta-island, is formed by the main branch of the river Kuban, which empties itself into the Black Sea, and a small branch of the same river, which flows into the Sea of Azof north of the old fortress of Temruk. The western or large part of the island stretches between the sea of Azof on the north and the Black Sea on the south, and is bounded on the west by the Strait of Yenikále, the antient Bosporus Cimmerius, and the Bay of Taman. The island resembles the open claws of a lobster, embracing the Bay of Taman. Its length is 57 miles, and its greatest breadth 22 miles, but the real surface is far from corresponding to these dimensions, the middle of the island being occupied by the large Temrukskoi Liman, or Lake of Temruk, and the whole of the remaining part being notched by creeks and bays in such a manner as to present rather the skeleton of an island than a real island. The south-western part of Taman, the antient peninsula of Corocondama (Pomp. Mela, i. 19; Strabo, p. 494. Casaub.) presents a solid mass traversed by several ranges of hills from 150 to 180 feet high: they run from west to east, and near the village of Sennaya-Balka form a bifurcation. One branch runs between the Kubanskoi Liman, or the lake formed by the Kuban before it reaches the sea, and the lake of Temruk, and terminates in a slip of land which divides this lake into two unequal parts. The other branch, the direc-

tion of which is north-east, forms the isthmus between the lake of Temruk on the east, and the bay of Taman on the west, and terminates before it reaches the isthmus between the lake of Temruk and the Sea of Azof. The north-western part of Taman, or the peninsula between the Sea of Azof and the bay of Taman, is no less elevated above the sea, but although it is a continuation of the mainland, it is separated from the eastern hills by a flat sandy isthmus, which seems to have been covered by the sea at a period not very remote from our own times. All these hills are mere masses of sand and pebbles cemented with clay. The higher part of them is barren, but the slopes, and the low grounds between them and the sea or the lakes, are covered with soil and fit for agriculture. They also make rich pasture-grounds. The isthmus between the Temrukskoi Liman and the bay of Taman, and principally that between the lake of Temruk and the Kubanskoi Liman, have a very pleasant aspect, being covered with the neat farmhouses of the Cossacks; and on the meadows there are numerous flocks of cattle, some of which are sent thither across the strait from the neighbouring coast of the Crimea. The eastern part of Taman is formed by two flat and narrow isthmuses, and a somewhat broader tract of lowland between the two branches of the Kuban. The whole of this country is marshy, partly covered with pastures and partly with a luxuriant vegetation of rushes and reeds, which, in the neighbourhood of Kaláus, as Dr. Clarke states, attain a height of from sixteen to twenty feet. Everywhere there is a struggle between land and water; gulfs become creeks and lakes, creeks are changed into marshes, and as soon as these get a continental aspect, the waters again swallow them up. In the rainy season, says Pallas, all this country is overflowed by the waters of the Kuban, and the higher part of Taman is separated from the continent by an immense lake which extends from one sea to the other; but notwithstanding the apparently overwhelming power of the waters, the solid element makes constant progress. Thus M. Dureau de la Malle is correct when, in his 'Géographie Physique de la Mer Noire,' he says that all the lakes on the shore of the Sea of Azof, which are separated from the sea only by flat and narrow isthmuses, have once been bays and gulfs, and that the barriers between them and the open sea are a deposit formed by the astonishing masses of mud and sand carried into this sea by the Don and its tributary rivers. As to the whole eastern part of the island of Taman, it is also a mere recent production of the immense quantities of clay and mud which the Sea of Azof and the Kuban have deposited before the mouth of this river. The western and elevated part however in its whole geognostical structure belongs to the opposite continent of the Crimea, from which it has apparently been separated by the current of the Cimmerian Bosporus. Two characteristic peculiarities of this latter part are the Sewernaya Kossa, a long but very flat and narrow slip of land which stretches from the north-west extremity of the northern peninsula in a south-west direction to the middle of the mouth of the bay of Taman; and the cluster of small islands, the principal one of which was known to the Byzantines by the name of Ateeh, which extend from Point Yunaya north-west till they reach the centre of the strait. These islands will probably become a continuous land, and by joining the opposite Sewernaya Kossa, will separate the whole bay of Taman from the Bosporus. Numerous small craters are situated on the ridge of the hills around the Bay of Taman, as well as along the lake of Temruk. They present all the external appearances of volcanoes; though the matter which they throw out is not lava, but a thick mud of a deep black colour, which they discharge at irregular periods. The largest of these craters is situated on the southern extremity of the north-west peninsula, and a description of the most remarkable eruption of it is given by Pallas in the work cited below. This traveller attributes these phenomena to the burning of an extensive layer of coals, upon which indeed the whole island of Taman seems to repose. The apparition of an island, which, on the 5th of September, 1799, suddenly rose from the Sea of Azof, near the coast of Temruk, a phenomenon which was preceded and accompanied by a kind of earthquake, and all the other symptoms of a volcanic eruption, was undoubtedly the effect of the same subterraneous cause. The new island however soon disappeared in the sea.

The Greeks knew this remarkable island under the name of Eion (Ἠιών), and founded several colonies in it. The most considerable of them were—Phanagoria, a famous commercial town, which contained a beautiful temple of Aphrodite of Apaturon (Strabo, p. 495. Casaub.); Kepos, or Kepi, a colony of the Milesians; Hermonassa, founded by the Ionians; and Achilleion: some ruins and marbles are the only traces that remain of their antient splendour. The island belonged for a long period to the kingdom of Bosporus, and was afterwards conquered by Pharnaces, the son of Mithridates. At the beginning of the middle ages it belonged to the dominions of the Goths, and afterwards of the Khazars, a Turkish people, renowned for their industry and commerce. It was then known under the name of Tamatarkha. In the tenth century a Russian prince founded there the petty kingdom of Tmutarakan; the greater part of the inhabitants however were Tsherkessians and Turks, and, from the time of the invasion of the Mongols, the Tartars remained the only masters of it. Numerous old tombs still attest their long residence on the island. They were at last driven out by the Russians, who repeopled the country with Cossacks in order to defend it against the invasions of the Tsherkessians beyond the Kuban. There are now only two towns: Tmútarakán, the Tamatarkha of the middle ages and the Phanagoria of the Greeks; and the present town of Phanagoria, which was built by the Russians on the shore of the bay of Taman, three miles east from Tmútarakán, on account of its harbour being deeper than that of the latter town.

(Pallas, *Bemerkungen auf einer Reise in den Südlichen Provinzen des Russischen Reiches;* Dr. Clarke, *Travels in Russia.* The best map of the island of Taman is contained in the great Atlas of Russia published at St. Petersburg; the map in Pallas's *Bemerkungen* is also good; that of Dr. Clarke has some interest for lovers of antiquities, but is far from being geographically exact.)

TAMA'NDUA. [Ant-Eater, vol. ii., p. 65.]

TAMARICA'CEÆ, a small natural order, belonging to the syncarpous group of polypetalous Exogens. The species are either shrubs or herbs, having straight rod-like branches, with alternate entire leaves, resembling scales; the flowers are in dense spikes or racemes. The calyx is 4-5-parted, persistent; the petals inserted into the calyx, both with imbricate æstivation; stamens hypogynous, distinct or united, equal in number with the petals or twice as many; ovary superior, with a short style and 3 stigmas; fruit a capsule, 3-valved, 1-celled, with numerous seeds, which are comose; embryo straight with an inferior radicle.

Tamarix germanica. *a*, cutting, showing the straight branches and scale-like leaves; *b*, single flower; *c*, flower with calyx and corolla removed showing monadelphous stamens; *d*, capsule with comose seeds escaping.

This order is placed by De Candolle with those which have perigynous stamens, but there is no doubt now that

it has hypogynous stamens, although closely related to the perigynous order Illecebraceæ. It has also affinities with Portulaceæ, Lythraceæ, Onagraceæ, and Reaumuriaceæ.

The species are found only in the Old World; the greatest number being met with in the basin of the Mediterranean. According to Ehrenberg, the order is bounded on the south by the 8th or 9th parallel of N. lat., and on the north by that of 50° and 55°, in Siberia, Germany, and England.

The plants of this order are innocuous, and all are more or less astringent; and their ashes after burning are remarkable for possessing a large quantity of sulphate of soda. Myricaria Germanica is recommended as a diuretic. [Tamarix.]

TAMARINDS, *Medical Properties of.* Of the two varieties of the only species of this genus, the fruit is much larger in the East Indian than the West Indian. The shell being removed, there remains the flat square hard seeds, imbedded in a pulp, with membranous fibres running through it. In the East Indies the pulp is dried, either in the sun, and this is used for home consumption, or with salt added, and dried in copper ovens, which kind is sent to Europe. (Crawfurd's *Indian Archipelago.*) This sort, called natural tamarinds, is much darker and drier than the West Indian, which are called prepared tamarinds.

The West Indian tamarinds reach maturity in June, July, and August, when they are collected, and the shell being removed, they are put into jars, either with layers of sugar put between them, or boiling syrup poured over them, which penetrates to the bottom. Prepared tamarinds therefore contain much more saccharine matter than the others. According to Vauquelin, prepared tamarinds contain per cent. citric acid 9·40, tartaric acid 1·55, malic acid 0·45, bitartrate of potash 3·25, sugar 2·5, gum 4·7, vegetable jelly (peeten) 6·25, parenchyma 34·35, water 27·55. This prepared pulp has a pleasant acid astringent taste, with a somewhat vinous odour.

It presents an example of one of those natural combinations of gummy, saccharine, and acid principles which are of such great utility in hot climates. It is used not only in India, but in Africa, as a cooling article of food, and the travellers across the deserts carry it with them to quench their thirst. In Nubia it is allowed to stand in the sun till a kind of fermentation takes place: it is then formed into cakes, one of which dissolved in water forms a refreshing drink. In India a kind of sherbet is made with it, and by the addition of sugar it becomes a source whence vinegar is readily obtained. In the fevers and bilious complaints, and even dysenteries of these climates, it proves highly serviceable; in small quantity it acts as an astringent, but in larger it proves laxative. Boiling water poured over tamarinds yields a drink which is very grateful in the inflammatory complaints of our own country, particularly in the bilious fevers of autumn. An agreeable whey may be made with it, by boiling two ounces of tamarind-pulp with two pints of milk. Tamarinds are frequently given along with senna, but they are said to lessen its purgative property. They form an ingredient in the confectio sennae and confectio cassiae.

In times of scarcity in India the seeds are eaten, being first toasted and then soaked for a few hours in water, when the dark skin comes easily off; they are then boiled or dried, and taste like common field-beans.

TAMARIND'S, the name of a genus of plants belonging to the Rectembryous division of the natural order Leguminosæ. It possesses the following characters:—calyx cleft, tubular at the base, the three upper lobes are reflexed, the two lower ones joined together, but usually indentate at the apex; petals 3, alternate with the three upper lobes of the calyx, the middle one cucullate and the lateral ones ovate; the stamens are 9 or 10 in number, two or three of which are longer than the others, united at the base, and bearing anthers, whilst the remainder are sterile; the fruit is a legume seated on a pedicel, 1-celled, compressed, with from 3 to 6 seeds, and the valves filled with pulp between the endocarp and epicarp, their inner and outer lining; the seeds are ovato-quadrate in form, possessing cotyledons unequal at the base.

There are only two species belonging to this genus, both of which are trees with abruptly pinnate leaves, bearing many pairs of small leaflets and racemes of flowers.

The *Tamarindus Indica*, the East Indian Tamarind, was the earliest known species, for a knowledge of which, in Europe, we are indebted to the Arabians. Dr. F. Hamilton, in his commentary on the Hortus Malabaricus, remarks on the specific designation of this plant, that it is 'a vile pleonasm,' the fact of its being Indian being referred to in the generic name *Tamar-Indus*, whence our word Tamarind. The Indian Tamarind is distinguished by its elongated legumes, which are six times or more longer than they are broad. It is a native of various districts in the East Indies and also of the tropical parts of Africa. It forms a handsome tree with spreading branches bearing leaves of a light colour and flowers with a straw-coloured calyx and yellow petals, streaked with red: the filaments of the stamens are purple and the anthers brown. The timber of this tree is very firm, hard, and heavy, and is applied to many useful purposes in building.

The second species is the *Tamarindus Occidentalis*, the West Indian Tamarind, which is distinguished from the other by possessing short legumes not more than three times longer than they are broad. It is a native of South America and the West India Islands, forming also a large spreading tree, with yellowish flowers streaked with red and purplish stamens.

These plants may be grown in this country, by sowing the seeds, which can be easily obtained, in a hot-bed, and when the young plants obtain a height of two or three inches, planting them out in separate pots. For the medical and dietetic properties of the tamarind see Tamarinds.

TAMARIX, the name of a genus of plants, the type of the natural order Tamaricaceæ. It has a 4- or 5-parted calyx; 4 or 5 petals; 4 or 5 stamens alternating with the petals, united at the base; a tapering ovary with 3 stigmas: erect tufted seeds, the tuft being composed of a number of hairs proceeding from the apex of the seed. The species have generally paniculated spikes of small flowers of a red colour.

T. gallica, the French tamarisk, is a glabrous glaucous shrub, with minute acute leaves clasping the stem, with slender lateral spikes of flowers, five times longer than broad. This species is a native of France, and also along the Mediterranean: it is also a native of the coasts of Cornwall, Hampshire, and Sussex, in England. Ehrenberg has described a great number of varieties of this species, one of which, the *T. g. mannifera*, known by its glaucous powdery appearance, he says, produces the manna of Mount Sinai. This manna however does not contain any crystallizable mannite, but, according to Mitscherlich, consists of nothing more than a mucilaginous sugar. This is one of the species of this genus remarkable for the large quantity of sulphate of soda which its ashes contain.

T. Indica, the Indian Tamarisk, is a glabrous greenish plant, with stiff twiggy branches; short ovate acute leaves with white edges; elongated spikes of flowers, with bracts shorter than the flowers and longer than the pedicels, and stamens longer than the corolla. This plant is a native of the East Indies. It is subject to the attacks of a cynips, which produce galls that possess astringent properties, and, according to Dr. Royle, they are on this account used in medicine by the native doctors of India. The same property also renders them valuable in dyeing. Other Indian species of the Tamarisk produce galls, which are used for the same purposes as those of *T. Indica*.

T. Africana, the African Tamarisk, is a glabrous glaucous shrub, with lanceolate imbricated leaves, with dense, scaly, simple, sessile racemes, with ovate chaffy bracts, and a 3-valved capsule. This is a native of the sands along the shores of the Mediterranean. It is found in Mauritiana, around the Bay of Naples, in Egypt, and in the Levant. It has very much the appearance of *T. Gallica*, but its flowers are larger, and bark darker. Like *T. Gallica*, its ashes yield a large quantity of sulphate of soda. The bark, as in most of the species, is slightly bitter and astringent, and has been used in medicine as a tonic.

T. Orientalis, the Eastern Tamarisk, is a tree attaining a height of from 10 to 20 feet: it is glabrous all over, with minute, distant, sheathing, mucronate leaves, with slender lateral spikes of flowers, and a 4-valved capsule. This is a native of Arabia, Persia, and the East Indies, and is one of the largest and most elegant of the species of the Tamarisk. One of the finest specimens of this tree existing is at Babylon. The *T. Chinensis* appears to be a variety of this plant.

Nearly all the species are elegant and delicate shrubs,

deserving a prominent position in the shrubbery. The hardy species do not require much care in their cultivation. They will grow in almost any soil or situation, and may be propagated by cuttings planted out in the open ground either in the spring or autumn, where they will readily strike root. Those requiring heat and protection thrive best in a soil composed of loam and peat, and may also be propagated by cuttings placed in sand under a hand-glass.

TAMA'TIA, Cuvier's name for the *Puff-Birds*.

Mr. Swainson, in addition to his description in the *Zoological Illustrations*, speaking of these birds in his *Classification*, says, that they sit for hours together on a dead or withered branch, from which they dart upon such insects as come sufficiently near, and that the Hermit birds (*Monassa*, Vieill.) have similar habits. [BARBETS, vol. iii., p. 434; KINGFISHERS, vol. xiii., p. 227.]

TAMAULIPAS. [MEXICAN STATES.]

TAMBOW, a province of Great Russia, is situated between 51° 30′ and 53° 20′ N. lat., and between 39° 40′ and 43° 40′ E. long. The area is 24,200 square miles, and the population 1,600,000. It is bounded on the north by Nischnei-Novgorod, and for a very small distance on the north-west by Wladimir; on the south by Woronesh; on the west by Riasan, Tula, and Orel (by the two last for a very small distance); and on the east by Penza.

This government is a uniformly level country, without mountains, large rivers, or considerable lakes: on the north there are great forests and on the south extensive steppes. The soil in the northern half is sandy, marshy, and poor: in the southern part it mostly consists of loam or black mould, and is fertile and productive. The steppes produce excellent pasturage, and when they have been brought under cultivation, make good arable land: they are designated as steppes only because they are destitute of wood. The river Oka enters the government from Riasan, but passes only through one circle, where it is joined by the Mokscha, a considerable stream of which the Zna is a tributary. The Oka runs northwards to join the Volga. Another great Russian river, the Don, passes through a small part of the government. In the forests on the north there are marshes which might easily be drained. The mineral-waters at Lepetzk are celebrated and much frequented. The climate is temperate and healthy, but colder in winter than in Tula and Riasan, which seems to be owing to the slope of the open plains being towards the north.

The northern part of Tambow has a poor soil, but the south is very fertile, and this province ought to be a corn country if a better system of cultivation were introduced. In the south the land does not require to lie fallow, and needs no manure, but acquires from the feeding of cattle sufficient strength to produce fresh crops, which generally yield from five to ten fold. In the north the land is indeed not manured, but after yielding five or six crops must be fallow for some years; and then it produces from three to five fold. All kinds of corn usually grown in Russia are raised, wheat, rye, oats, millet, and buckwheat, peas and other pulse; poppies, great quantities of hemp, but barley, flax, and hemp are cultivated only in some circles. Horticulture is in a very backward state, for though there are many gardens, only the most ordinary vegetables are cultivated; some hops are grown in the gardens, but there is little fruit, and that of the most ordinary kinds. Though the forests are so extensive, it is only in the northern circles that there is sufficient wood for fuel and building. The crown forests supply timber for the navy: in their vicinity the inhabitants are for the most part carpenters, coopers, and cartwrights, or employed in making pitch, tar, lamp-black, and charcoal. The breeding of cattle is carried on to a very great extent in the fine pastures and meadows of the steppes. The steppe from Tambow to Nova Khopertskaja-Krepost is covered with immense herds of oxen and horses. Oxen are used for draught, and great numbers are fattened for exportation. Sheep and swine are bred in great numbers, but the wool of the sheep is coarse: of late years the breed has been improved by the importation of merinos. Domestic poultry suffices for the consumption of the inhabitants: there is little game, and fish is by no means plentiful. Among the wild animals are the marmot and the hamster. Great quantities of bees are kept. The mineral products are lime, freestone, iron, and some saltpetre.

The manufactures of this government are unimportant: the peasantry barely make their own clothing: in some parts they manufacture wooden utensils, and agricultural implements, which they take to the fairs. A great advance has however been made within the last twenty-five years. The brandy-distilleries are numerous. The export trade in the products of the country is very considerable. The principal articles are wheat (1,200,000 chetwerts, or 864,000 English quarters), cattle, honey, tallow (400,000 poods, or about 500 English cwt.), butter, cheese, wool, hemp, iron, brandy, hides, coarse cloth, and wooden wares. Properly speaking there is no great commercial town. Tambow, Selatma, and Morschansk alone have some commerce with foreign countries.

The great majority of the inhabitants are Russians. There are some thousands of converted Tartars and Mordwins, and a few gypsies. These Tartars and Mordwins live in the same manner as the Russians, but retain their own dialect, and live apart from the Russians, and generally intermarry with their own people. The religion of the Mohammedan Tartars requires a different mode of life. Among these various nations the Tartars are the most civilised, have the most knowledge, and the purest morals, and enjoy the most prosperity.

Education is at a low ebb. According to Schnitzler, only 1 out of 325 of the population receives any school instruction. The only printing-office belongs to the government.

The Greek church is under, the bishop of Tambow and Schazk, who has in his diocese 739 parishes and 6 monasteries. The Mohammedan Tartars have their mosques, imams, and teachers.

TAMBOW, the capital of the government, is situated nearly in the centre of the province, on the river Zna, in 52° 44′ N. lat. and 41° 45′ E. long. It is a large town, with 20,000 inhabitants, and was founded in 1636, as a bulwark against the Nogay Tartars. Scarcely any traces of the antient fortifications now remain. There is nothing remarkable in the town, which has however been much improved in its appearance since the beginning of this century. Almost all the houses are built of wood: the principal buildings are the monastery of Our Lady of Casan, in which there are two churches; seven stone and six wooden churches, the gymnasium, and the civil hospital. There is a military school, founded and endowed by the nobility in 1802, a seminary for priests, and a district school. The bishop resides in this city. The inhabitants manufacture shawls, kersey, sailcloth, cordage, and woollen cloth; and there is an Imperial alum and vitriol manufactory. The inhabitants carry on some trade, but their chief occupation is agriculture.

The following are the other chief towns. Jelatma, the most northerly town in the government, situated on the left bank of the Oka, carries on by means of that river a very great trade with Moscow: it has ten churches, eight of which are of stone: the inhabitants, 6000 in number, have some manufactures of woollen cloth, vitriol, and sulphur. Koslow, situated on the Lesnoi Woronesh, has above 8000 inhabitants, who follow various trades and professions: near the town is the convent Troitzkoi, where a great annual fair is held. There are eight churches, of which five are of stone: the principal trade of the town is in oxen, salt meat, and hides. Lipetsk, on the Woronesh, near the north extremity of the government of that name, a town with 6500 inhabitants, is celebrated for its mineral-waters, which were first used in the reign of Peter the Great. Morschansk, a town of 6000 inhabitants, situated on the Zna, has manufactures of linen, sail-cloth, cordage, and tallow, and a brisk trade in corn, cattle, and honey. (Hassel, *Geography;* Stein; Hörschelman; Schubert; Schnitzler.)

TAMBURI'NI, PIETRO, born at Brescia, in 1737, studied in his native town, took holy orders, and was made professor of philosophy, and afterwards of theology, in the episcopal seminary of Brescia. After filling those chairs for twelve years, he was invited to Rome, where Clement XIV. (Ganganelli) made him director of the studies of the Irish College, in which situation he remained for six years. In 1778 he was recalled to Lombardy by the empress Maria Theresa, and appointed professor of theology in the university of Pavia, and at the same time director of the studies of the German Hungarian college in that city, and also censor of the press. In 1795 he was

made Professor Emeritus, with a pension. In 1797, when the French invaded Lombardy, Tamburini was obliged by the new government to resume active duties at Pavia, as professor of moral philosophy and of 'jus naturæ,' an arduous tax in those times of confusion of ideas and of barefaced licentiousness. Tamburini boldly fulfilled his duties, and effected some good by proclaiming wholesome principles from his chair. Shortly afterwards his chair was suppressed, but he was appointed rector of the lyceum of his native town, Brescia. When Bonaparte assumed the government in France and North Italy, Tamburini was sent again to Pavia as professor of moral philosophy and of 'jus naturæ et gentium,' in which chair he continued for eighteen years, till some years after the Restoration, when the emperor Francis made him again Professor Emeritus and præsul of the faculty of law and politics in the university of Pavia. Tamburini was also a knight of the order of the Iron Crown. He died at Pavia, in March, 1827, at ninety years of age, a few days after the death of his brother professor, Volta. His remains were buried with the greatest honours, being followed to the grave by the whole of the professors and above six hundred students, with marks of sincere respect and deep regret.

The work for which Tamburini is mostly known is 'Idea della Santa Sede,' published anonymously at Pavia, in 1784. An extract from the author's preface will convey some idea of the nature of this work: 'It very often happens that to the most common and hacknied expressions a vague and indeterminate meaning is attributed. A word was originally fixed upon to signify a certain thing. The idea of it was perhaps clear and precise in its origin, but as in the course of time the ideas of men change, the word is still retained, though people attach to it different meanings. Hence obscurity and confusion and interminable disputes arise, and still the sound of the disputed word is kept up, without conveying any distinct idea of what it means. Numberless examples might be quoted of such an occurrence. For instance, in our own times everybody speaks of the Holy See, the Apostolic See, the chair of St. Peter, the Roman church, which are so many expressions signifying the same thing, and which in antient times expressed a simple and clear idea, but which now convey to the minds of people the most vague and indeterminate notions. Things the most disparate are identified; people confound one subject with another, the see with the incumbent, the chair with the court of Rome, the court with the church; and from this medley arises a confusion of ideas through which every decree that proceeds from Rome becomes invested with the most respectable authority of the chair of St. Peter, of the Apostolic See, of the church of Rome—a confusion followed by the most pernicious consequences not only to local churches, but also to the universal church, and to the Apostolic See itself. In order to support certain decretals which emanated from Rome, some short-sighted theologians have attributed to the Roman See new prerogatives unknown to the earlier ages of the church, and they have had recourse to a supposed infallibility. . . . Other men have contested these prerogatives, and in the warmth of the controversy the real claims of the Holy See have been overlooked and forgotten. . . . One party has maintained that, on the plea of infallibility, every decision emanating from Rome ought to be received with blind obedience, whilst the other party has imagined that by overthrowing the privilege of infallibility every authority ascribed to it can be boldly denied. . . . Both these extremes proceed from the want of just and exact notions on the nature, the character, and the properties of the Holy See. The present work is intended to establish these notions. A little French book fell into my hands, entitled 'Dissertation Canonique et Historique sur l'Autorité du Saint Siége, et les Décrets qu'on lui attribue.' In the first part the author has well explained the idea of the Holy See and of the Congregations sitting at Rome; and in the second part he has maintained the primacy of that see. I have adopted the most important principles of this little work, compressing or enlarging its various parts, and fitting the whole to the wants of our times and country. I have explained also the essential rights annexed to the primacy of the Roman see, and have given some general rules in order to calculate the value and merit of the Roman decretals, and to make our own conduct practically harmonize with the obedience which we owe to the authority of the see of Rome.'

At the appearance of Tamburini's work it was stigmatized as Jansenistical, although the author has not gone perhaps so far as some of the French Jansenists, or as Bishop Ricci and his synod of Pistoia. [JANSENISTS; PIUS VI.] The reasoning is closely argumentative, and supported by numerous references. Several refutations of it were published at Rome and other towns of Italy. The other works of Tamburini are—1, 'Introduzione allo Studio della Filosofia Morale,' Milan, 1797; 2, 'Lezioni di Filosofia Morale e di Naturale e Sociale Diritto,' 4 vols., Pavia, 1806-12; 3, 'Elementa Juris Naturæ,' Milan, 1815; 4, 'Cenni sulla Perfettibilità dell' Umana Famiglia,' Milan, 1823; in which the author refutes the exaggerated notions of indefinite perfectibility and universal happiness in human societies. The philosophy of Tamburini is of the Eclectic kind.

TAMPI'CO. [MEXICAN STATES.]

TAMUL. [HINDUSTAN, p. 228.]

TAMUS, the name of a genus of plants belonging to the natural order Dioscoreaceæ. This genus is dicecious, the stamens growing on one plant, and the pistils on another. The flowers are alike in having a perianth, which is 6-parted, the calyx and corolla being undistinguishable. In the male flowers there are 6 stamens. In the female flowers the remains are seen of 6 abortive stamens; the ovary is trilocular; the style trifid, with 3 stigmas; the fruit a berry. This genus is supposed to be the *Uva Taminia* of Pliny: hence its present name.

Tamus communis, the common Black Briony, has undivided cordate, acuminate leaves, and is a very common plant in hedges and thickets throughout Europe. It is a frequent plant in England. It has a long twining stem, spreading in all directions, and reaching from branch to branch of hedges and thickets: its flowers are greenish-white; the fruit is of a red colour, and hangs in bunches from its trailing branches. The berries are likely to be plucked and eaten by children: they are not however poisonous, although the whole plant contains a bitter acrid principle, which renders it unwholesome. This acrid principle is destroyed by heat; and as the roots of this plant contain a great deal of starch or fecula, a wholesome and nutritious food may be obtained from them by washing and boiling. On the surface of the roots are found blackish tubercles, which contain a larger quantity of acrid principle than the rest of the plant, and these should be removed previous to preparing the roots for eating. The young shoots of this plant taste, when boiled, like asparagus, and are eaten by the Moors with oil and salt.

TAMWORTH, a municipal and parliamentary borough on the border of Staffordshire and Warwickshire: the municipal borough, which includes the greater part of the town, and the parish, which is far more extensive, having an area of 12,920 acres, are divided between the two counties: the parish is partly in the northern and partly in the southern division of Offlow hundred in the county of Stafford, and partly in Hemlingford hundred in Warwickshire. The church is in Staffordshire, on which account the town is commonly described as being in that county. Tamworth is 102 miles in a direct line north-west of the General Post-office, London, or 129 miles by the London and Birmingham Railway to Hampton in Arden, and from thence by the Birmingham and Derby Junction Railway.

The town first comes into notice in the time of the Heptarchy: several of the Mercian kings appear, from the date of charters granted by them, to have had their residence at Tamworth. In the Danish wars a fort was built here in the reign of Edward the Elder (A.D. 913) by his sister Ethelfleda, lady of Mercia, who died at Tamworth, A.D. 920, and Mercia passed under the direct dominion of Edward, who received the submission of the Tamworth men, A.D. 922. Shaw (*Hist. of Staffordshire*) ascribes to

Ethelfleda the mound on which the present ruins of the castle stand, but the ruins themselves are of later date. An old ditch, yet visible, called 'the king's dyke,' which surrounds the town on three sides, is supposed by Shaw to be of yet greater antiquity than the time of Edward. In the Saxon 'Chronicle' the town is called Tamaweorthige, Tamewcorthige, Tamanweorthe, or Tamweorthe: in other antient writings the orthography is still further varied. The place is not described in 'Domesday;' but the 'burgenses' (burgesses) of Tamworth, are mentioned in that record, in the notice of other places.

After the Conquest, the castle and adjacent territory were granted to Robert Marmion, hereditary champion to the dukes of Normandy; and afterwards, on the extinction of the male line of his family in the time of Edward I., passed to the family of Frevile. The castle now belongs to Marquis Townshend. Sir Walter Scott has enumerated 'Tamworth tower and town' among the possessions of his fictitious Marmion: but the family had become extinct long before, as observed by Sir Walter in the Appendix to his poem.

The town stands on the north bank of the rivers Tame and Anker, just at their junction, and consists of several streets not very regularly laid out. The streets are paved, but had not been lighted when the Municipal Boundary Commissioners' Report was drawn up (*Parl. Papers for* 1837); the inhabitants were however about to assess themselves for the purpose. 'The church is a large and handsome edifice, with a fine tower, and a crypt under part of the church. Some portions are of decorated date, and some perpendicular, and both good: some of the windows have had very fine tracery. In the tower is a curious double staircase, one from the inside and one from without, each communicating with a different set of floors in the tower.' (Rickman's *Gothic Architecture.*) The remains of the castle are on a mound close to the Tame: they are of various periods, and some modern buildings have been added to adapt the whole to the purposes of a modern residence: the castle commands a fine prospect. There are some Dissenting places of worship; an almshouse, founded by Guy, the founder of Guy's Hospital in Southwark; a town-hall, with a small and inconvenient gaol beneath; and two bridges, one over the Tame, the other over the Anker.

The population of the municipal borough in 1831 was 3537, that of the whole parish (containing several hamlets and townships) 7182. Some manufactures are carried on; but the whole number of men employed in them in the parish was, in 1831, only 38. Some coals and brick-earth are dug in the neighbourhood, and bricks and tiles are made. The market is on Saturday: there are three chartered fairs for cattle and merchandise, and several new fairs for cattle only; some of them held at Fazeley in the parish. The Coventry Canal passes near the town.

Tamworth was a borough by prescription; but the town having declined and ceased to be regarded as a corporation, was incorporated anew by letters patent of Queen Elizabeth: the governing charter is one of Charles II. By the Municipal Reform Act the borough has four aldermen and twelve councillors, but is not to have a commission of the peace except on petition and grant. The criminal jurisdiction of the corporation had fallen into disuse before the passing of that act, as well as the court of record: quarter-sessions were held, but for civil purposes only.

Tamworth first sent members to parliament in the reign of Elizabeth: it still returns two members. The number of voters on the register in 1835-6 was 531: in 1839-40, 501.

The living of Tamworth is a perpetual curacy, of the clear yearly value of 170*l.*, with a glebe-house. There are in the parish the perpetual curacies of Fazeley, Wigginton, and Wilnecote, of the clear yearly value of 235*l.* (with a glebe-house), 92*l.* and 90*l.* respectively: the curate of Tamworth presents to Wigginton and Wilnecote. There are also in the parish two chapelries, Amington and Hopwas.

There were in the borough, in 1833, three endowed and three unendowed day-schools, with 183 children, namely 142 boys, 21 girls, and 20 children of sex not stated; and three Sunday-schools, with 203 children, viz. 97 boys and 106 girls. In the rest of the parish were one infant-school, partly supported by subscription, with 88 children, namely 41 boys and 47 girls; ten day-schools of all kinds, with 96 boys, 80 girls, and 80 children of sex not stated, making 256 children in all; and three Sunday-schools, with 288 children, namely 150 boys and 138 girls. (Shaw's *Staffordshire; Parliamentary Papers.*)

TANA-ELF. [TRONDHEIM.]

TANACETUM, a genus of plants belonging to the natural order Compositæ, and the suborder Corymbiferæ or Asteraceæ. The involucre is imbricated and hemispherical. The receptacle is naked; the flowers of the ray are 3-toothed, those of the disk 5-toothed, tubular, and hermaphrodite. The fruit, an achenium, is crowned with a membranous margin, or pappus. The flowers are yellow.

The most common species is the *Tanacetum vulgare*, common *Tansy*. It has bipinnatifid leaves, with serrated sections or laciniæ. This plant is abundant in Great Britain and throughout Europe, on the borders of fields and road-sides. It possesses in a high degree the bitterness of the whole order Compositæ, which, in the section Corymbiferæ, is combined with a resinous principle. It is recommended and has been extensively used in medicine as an emmenagogue and anthelmintic. Although the flavour and smell of this plant are both at first disagreeable, a taste for it may be acquired, and it has been used in cookery for the purpose of flavouring puddings and sauces. The young shoots yield a green colouring-matter, and are used by the Finlanders for the purpose of dyeing their cloths of that colour. It is said that if meat be rubbed with the fresh leaves, it will not be attacked by the flesh-fly.

TA'NAGERS. The genus *Tanagra* of Linnæus stands, in the 12th edition of the *Systema Naturæ*, between *Emberiza* and *Fringilla*, in the order *Passeres*.

Cuvier characterises the genus as having a conical bill, triangular at its base, slightly arched at its *arête*, and notched towards the end: wings and flight short. He observes that they resemble our sparrows in their habits, and seek for seeds as well as berries and insects. The greater part, he remarks, force themselves upon the attention of the spectator of an ornithological collection by their vivid colours. He places the genus between the Drongos (*Edolius*, Cuv.) and the Thrushes (*Turdus*, Linn.), thus subdividing it:—

1. The Euphonous or Bullfinch Tanagers (*Euphones, ou Tangaras Bouvreuils*).

These have a short bill, presenting, when it is seen vertically, an enlargement on each side of its base: tail short in proportion.

Examples, *Tanagræ violacea, Cayennensis*, &c.

2. The Grosbeak Tanagers.

Bill conic, stout, convex, as wide as it is high; the back of the upper mandible rounded.

Examples, *Tanagræ magna, atra*, &c.

3. Tanagers, properly so called.

Bill conic, shorter than the head, as wide as it is high, the upper mandible arched and rather pointed.

Examples, *Tanagræ Tulao, tricolor*, &c.

4. Oriole Tanagers (*Tangaras Loriots*).

Bill conic, arched, pointed, notched at the end.

Examples, *Tanagræ gularis, pileata*, &c.

5. Cardinal Tanagers.

Bill conic, a little convex, with an obtuse projecting tooth on the side.

Examples, *Tanagræ cristata, brunnea*, &c.

6. Ramphocele Tanagers.

Bill conic, with the branches of the lower mandible convex, backwards.

Examples, *Tanagræ Jacapa, Brasilia*, &c.

The views of Mr. Vigors on the subject of this group will be found in the article FRINGILLIDÆ.

Mr. Swainson remarks that the *Tanagrinæ*, or *Tanagers*, form that group which is probably the most numerous, as it certainly is the most diversified of all those in the comprehensive family of the *Fringillidæ*. As the dentirostral division of that family, it is, he observes, typically distinguished from all the others by the bill having a distinct and well-defined notch at the end of the upper mandible, the ridge or culmen of which is much more curved than the gonys; or, in other words, the culmen is more curved downwards than the gonys is upwards: this inequality, he further states, as in the genus *Ploceus*, very much takes off from that regular conic form of bill so highly characteristic

of the greater number of the finches; so that the combination of these two characters is, he thinks, perhaps the best distinction of the whole group. Another peculiarity, he adds, of these birds consists in their geographic range; for the whole, as far as has hitherto been ascertained, are natives of the warmer parts of America, being most abundant in those regions nearest to the equinoctial line. 'They are,' says Mr. Swainson in continuation, 'in general small birds, the largest being intermediate between a sparrow and a thrush, while the majority do not exceed the size of a linnet; some few are even smaller. It is quite evident, from the great strength of bill possessed by some, and the notch which is conspicuous in all, that these birds feed upon seeds and creeping insects picked from the branches of trees, for very few of them are ever seen upon the ground. Their colours in general are bright; and, in a large number, particularly rich and beautiful. The little birds forming the genus *Aglaia*, in fact, are ornamented with the most vivid hues or glossed with rich reflections of gold, rendering them inferior only to the Humming Birds. Some possess considerable vocal powers; and the notes of the subgenus *Euphonia*, as its name implies, are said to be particularly musical. The impossibility however of providing the Tanagers with their native sweet food has prevented them from ever being brought alive to the European menageries, to which their beauty would render them the greatest ornaments.'

Mr. Swainson then dwells on the obscurity which attends the examination of this group, which he states to be one of the most difficult to be understood in the whole circle of ornithology. He points out, for instance, that the comparative strength of the bill is so variable in the same subgenus, that such variation, indicative of genera in other families, is in this no more than a discrimination of sections or species. Nothing, according to him, can illustrate this fact more than the affinity between *Pitylus* and *Tardivola*. Looking to the types of each, he observes, we should say that they did not belong even to the same subfamily; for the bill of the first is nearly as large as in the hawfinches (*Coccothraustes*, Hawfinch), while that of *Tardivola* is so comparatively slender that it seems more akin to the Larks than to the Tanagers; and yet, he remarks in continuation, between these two extremes or types, he had, when he wrote, before him such a perfect series of graduated forms, wherein not only the bill, but all the other subordinate characters of the two groups, progress in such a perpetual and almost imperceptible manner, that he was actually at a loss to know where *Tardivola* ends and *Pitylus* begins. The foregoing affinity being admitted, and it should be remembered that some of the best ornithological writers have placed it as a genus in a totally different family, Mr. Swainson next proceeds to inquire into the cause of so remarkable a variation in the bill of such closely-united species. He first states that nearly the whole of the seed-eating birds of Tropical America are composed of the Tanagers, which, in those regions, supply the place of the other finches so abundant in all parts of Europe. The innumerable small and hard fruits produced in the American forests are, he observes, the appointed food of the Tanagers, the parrots living principally upon the larger nuts, and the bill of the former birds is constructed accordingly. After noticing the disparity of the bills in the finches, taking the common linnet and the hawfinch for example, he remarks how little reliance can be placed on such diversity in determining genera: but this, he observes, will not explain the great difference which often exists in the size and plumage of species which all writers agree in arranging within the limits of the same subgenus; and he takes the restricted genus *Pitylus*, Cuv., as an example. Some of the species of that genus are green, some black, others grey; and in size they vary from the dimensions of a sparrow to those of a small thrush.

The doubts which, in Mr. Swainson's opinion, hang over the correctness of the views which he entertained with respect to the natural affinities of these birds, may, he says, be said to hinge almost entirely upon his not having been able to examine specimens of *Fringilla Zena*, which has certain peculiarities which lead him to expect that it forms the type of one of the principal divisions among the Tanagers, or that it connects his genus *Aglaia* with *Pipillo*. On the first supposition, *F. Zena* would, according to Mr. Swainson, constitute the passage from the true sparrows (*Pyrgita*) to the subgenus *Tanagra* proper; while by the second, *Pipillo* would stand intermediate between *Aglaia* and *Tanagra*, and thus constitute the rasorial genus of the whole subfamily; and this latter arrangement appears to him to be the natural one. He considers that the two typical groups or genera are *Tanagra* and *Phænisoma*; while those which he thinks aberrant are *Nemosia*, *Aglaia*, and *Pipillo*. It was only between the two last of these that he had not as yet discovered any affinity sufficiently strong to justify the belief that these five genera form a circle more or less complete; the difficulty being how to connect *Aglaia* with *Pipillo*. He then takes a review of the genera, for which we must refer our readers to the work itself; and, in the *Synopsis* at the end of the volume, makes the *Tanagrinæ*, which he places between the *Coccothraustinæ* and the *Fringillinæ*, consist of the following genera and subgenera, all of which he characterizes:—

Tanagrinæ.

Subfamily Character.—Bill equally conic; the upper mandible more or less arched, and very distinctly notched. Feet formed for perching. Claws broad and fully curved.

Genera.

Tardivola, *Tanagra* (with the subgenera *Pitylus*, *Tanagra*, and *Ramphopis*). *Phænisoma* (with the subgenera *Phænisoma*, *Tachyphonus*, and *Leucopygia*). *Nemosia*. *Aglaia* (with the subgenera *Euphonia* and *Tanagrella*). And *Pipillo* (with the subgenus *Arremon*). (*Classification of Birds.*)

The Prince of Canino (*Birds of Europe and North America*) places the *Tanagrinæ* between the *Fringillinæ* and the *Emberizinæ*. *Pyranga* is the only genus recorded as belonging to the *Tanagrinæ*.

Mr. G. R. Gray makes the *Tanagrinæ* the third subfamily of the *Fringillidæ*, arranging it between the *Coccothraustinæ* and *Fringillinæ*. The following genera are enumerated by Mr. Gray as belonging to the third subfamily:—

Emberizoïdes, Temm.; *Pipilo*, Vieill.; *Emberiagra*, Less.; *Arremon*, Vieill.; *Cissopis*, Vieill.; *Pitylus*, Cuv.; *Tanagra*, Linn.; *Saltator*, Vieill.; *Spindalis*, Jard. and Selby; *Ramphopsis*, Vieill.; *Lamprotes*, Sw.; *Pyranga*, Vieill.; *Lanio*, Vieill.; *Tachyphonus*, Vieill.; *Nemosia*, Vieill.; *Tanagrella*, Sw.; *Euphonia*, Desm.; *Calaspiza*, G. R. Gray; *Stephanophorus*, Strickl.; *Cypsnagra*, Less.

Mr. Gray, with his usual industry, gives the numerous synonyms of each genus. (*List of the Genera of Birds*, 2nd edition, 1841.)

We select Nuttall's description of the *Scarlet Tanager, or Black-winged Summer Red-Bird*, *Tanagra rubra*, Linn. (subgenus *Pyranga*).

The male is scarlet-red, with the wings and notched tail black: the base of the plumage is ash, then white. The female, young, and male in autumn, are dull green, inclining to yellow in the latter; yellow beneath; wings and tail dusky. Length about six inches and a half; alar extent ten inches and a half.

'This splendid and transient resident,' says Nuttall, 'accompanying fine weather in all his wanderings, arrives from his winter station in tropical America from the beginning to the middle of May, and extends his migrations probably to Nova Scotia as well as Canada. With the shy, unsocial, and suspicious habits of his gaudy fraternity, he takes up his abode in the deepest recesses of the forest, where, timidly flitting from observation, he darts from tree to tree like a flashing meteor. A gaudy sylph, conscious of his brilliance, and the exposure to which it subjects him, he seems to avoid remark, and is only solicitous to be known to his humble mate, and hid from all beside. He therefore rarely approaches the habitations of men, unless perhaps the skirts of the orchard, where he sometimes however builds his nest, and takes a taste of the early and inviting, though forbidden cherries.'

'Among the thick foliage of the tree in which he seeks support and shelter, from the lofty branches, at times, we hear his almost monotonous *tship-ŭrĭtee*, *tship-ĭdee*, or *tshŭkadee*, *tshŭkadee*, repeated at short intervals, and in a pensive under-tone, heightened by the solitude in which he delights to dwell. The same note is also uttered by the female when the retreat of herself and young is approached; and the male occasionally utters, in recognition to his mate, as they perambulate the branches, a low whispering *'tait*, in a tone of caution and tenderness. But besides these calls on the female, he has also, during the period of his incubation, and for a considerable time after,

a more musical strain, resembling somewhat, in the mellowness of its tones, the song of the fifing Baltimore. The syllables to which I have hearkened appear like *'tshoove 'wait 'wait, 'vehŏwit wait*, and *'wait, 'vehŏwit vea wait*, with other additions of harmony, for which no words are adequate. This pleasing and highly musical meandering ditty is delivered for hours, in a contemplative mood, in the same tree with his busy consort. If surprised, they flit together, but soon return to their favourite station in the spreading boughs of the shady oak or hickory. This song has some resemblance to that of the Red-eyed Vireo in its compass and strain, though much superior, the *'wait 'wait* being whistled very sweetly in several tones, and with emphasis; so that, upon the whole, our *Pyranga* may be considered as duly entitled to various excellencies, being harmless to the farmer, brilliant in plumage, and harmonious in voice.'

Nest, Food, &c.—The same author describes the nest (which is built about the middle of May, on the horizontal branch of some shady forest-tree, commonly an oak, but sometimes in an orchard tree) as but slightly put together, and usually framed of broken rigid stalks of dry weeds or slender fir-twigs, loosely interlaced together, and partly tied with narrow strips of Indian hemp (*Apocynum*), some slender grass-leaves, and pea-vine runners (*Amphicarpa*), or other frail materials; the interior being sometimes lined with the slender, wiry, brown stalks of the Canadian cistus (*Helianthemum*), or with slender pine-leaves; the whole so thinly platted as to admit the light through the interstices. The three or four eggs are dull blue, spotted with two or three shades of brown or purple, most numerous towards the larger end. As soon as their single brood, which is fledged early in July, is reared, they leave for the south, generally about the middle or end of August.

'The female,' says this interesting author in continuation, 'shows great solicitude for the safety of her only brood; and, on an approach to the nest, appears to be in great distress and apprehension. When they are released from her more immediate protection, the male, at first cautious and distant, now attends and feeds them with activity, being altogether indifferent to that concealment which his gaudy dress seems to require from his natural enemies. So attached to his now interesting brood is the Scarlet Tanager, that he has been known, at all hazards, to follow for half a mile one of his young, submitting to feed it attentively through the bars of a cage, and, with a devotion which despair could not damp, roost by it in the branches of the same tree with its prison.'

The food of this species consists mostly of winged insects, such as wasps, hornets, and wild bees, the smaller kind of beetles, and other *Coleoptera*. Seeds are supposed to be sometimes resorted to, and they are very fond of whortle and other berries.

It is in August that the moult of the male, when 'he exchanges his nuptial scarlet for the greenish-yellow livery of the female,' commences. (*Manual of the Ornithology of the United States and of Canada.*)

TANAGRI'NÆ. [Tanagers.]

TA'NAIS. [Don.]

TANARO. [Po.]

TANCRED, of Hauteville in Normandy, was a feudal baron who lived in the latter part of the tenth and beginning of the eleventh century. After doing military service for some years under Richard the Good, duke of Normandy, he retired to his hereditary mansion, where he lived poor, and reared up a numerous family of twelve sons and three daughters. All his sons were remarkable for their comeliness, their great strength, and their courage. The eldest, Serlon, followed William the Bastard in his conquest of England, and the others went successively to seek their fortune in Apulia, where Rainulf, another Norman adventurer, had already obtained the countship of Aversa from Sergius, duke of Naples. William, one of Tancred's sons, called 'Fier à bras,' or strong of arm, became count of Apulia, and after his death, his brother Robert, called Wiskard, or 'the wise,' became duke of Apulia and Calahria, and the founder of the Norman dynasty of Sicily. [Sicilies, Two, *History of.*] Their father Tancred died at a very great age at Hauteville. Traces of the château of Tancred, according to old popular tradition, were still seen a few years since in a pretty valley near Hauteville, four miles north of the town of Marigny, in the arrondissement of Coutances department of La Manche. (Gaultier d'Arc, *Histoire des Conquêtes des Normands en Italie, en Sicile, et en Grèce.*)

TANCRED, son of Eudes, a Norman baron, and of Emma, sister of Robert Wiskard, duke of Apulia, according to some (Gaultier d'Arc, *Histoire des Conquêtes des Normands en Italie, en Sicile, &c.*), and nephew of Bohemund, son of Wiskard, and prince of Tarentum according to others (Giannone and the authorities he quotes), was serving with Bohemund under Roger, duke of Apulia, son and successor of Wiskard, at the siege of Amalfi, A.D. 1096, when the report of the great crusade which was preparing for the East determined Bohemund, who was not on good terms with Duke Roger, to join the Crusaders. Tancred followed him with a vast number of men from Apulia and Calabria. The exploits, true or fabulous, of Tancred, in Syria and Palestine, have been immortalized by Tasso in his poem of 'La Gerusalemme.'

TANCRED, king of Sicily. [Sicilies, Two, *History of.*)

TANGENT. In the article Contact we have given the first notion on this subject, which we now resume in a somewhat more general manner, annexing the usual details of formulæ, but without proof.

It is usual to apply the word tangent to the tangent *straight line* only, on which see Direction: generalizing the definition, it will be as follows:—Of all curves of a given species, or contained under one equation, that one (B) is the tangent to a given curve (A) at a given point, which passes through that given point, and is nearest to the curve (A): meaning that no curve of the given species can pass through the given point, so as to pass between (B) and (A), immediately after leaving the point at which the two latter intersect.

To ascertain the degree of contact of two curves which meet in a point, proceed as follows. Let $y=\phi x$ and $y=\psi x$ be the equations of the curves, and a the abscissa at the point of contact; so that $\phi a=\psi a$. At the point whose abscissa is $a+h$, the difference of the ordinates of the curves is, by Taylor's theorem,

$$(\phi'a-\psi'a)\,h+(\phi''a-\psi''a)\frac{h^2}{2}+(\phi'''a-\psi'''a)\frac{h^3}{2.3}+\ldots.$$

as to which, generally speaking, it will be found that h can be taken so small that the series shall be convergent: if this be not so, the method of arresting the series given in Taylor's Theorem must be employed. Now of two series of the form $Ah^m+Bh^{m+1}+\ldots.$ the value of that in which m is the greater will diminish without limit as compared with the other, when h diminishes without limit. Consequently, every curve $y=\psi x$, which has $\psi'a=\phi'a$, will approach, before the point of contact is attained, nearer to $y=\phi x$ than any other in which $\psi'a$ is not $=\phi'a$. Again, when $\phi'a=\psi'a$, those cases of $y=\psi x$ in which $\psi''a=\phi''a$, will approach nearer to $y=\phi x$ than any in which $\phi''a$ is not $=\psi''a$; and so on. Hence, to make $y=\psi x$ have the closest possible contact with $y=\phi x$ when $x=a$;—give such values to the constants in $y=\psi x$ as will satisfy as many as possible of the equations $\phi a=\psi a$, $\phi'a=\psi'a$, $\phi''a=\psi''a$, &c. consecutively from the beginning. This is a brief sketch, which can be filled up from any elementary work; and the following are the principal results:—

1. When the string of equations is satisfied up to $\phi^{(n)}a=\psi^{(n)}a$, the contact is said to be of the nth order.

2. In contact of the nth order, the deflection $\phi(a+h)-\psi(a+h)$ diminishes with h^{n+1}, and vanishes in a finite ratio to it.

3. In contact of an even order, the curves intersect at the point of contact; in contact of an odd order, they do not intersect at that point.

4. When curves have a contact of the nth order, no curve, having with either a contact of an order inferior to the nth at the same point, can pass between the two.

5. A straight line, generally speaking, can have only a contact of the first order with a curve; and the equation to the tangent straight line of the curve $y=\phi x$, when $x=a$, is $y-\phi a=\phi'a(x-a)$. But if it should happen that $\phi''a=0$, $\phi'''a=0$, &c., up to $\phi^{(n)}a=0$, then for that point the tangent has a contact of the nth order. Thus, at a point of contrary flexure the tangent has a contact of the second order, at least, with the curve.

6. A circle, generally speaking, can be made to have a contact of the second order with a curve, and the equation

of the most tangent circle, or circle of CURVATURE, to the curve $y=\phi x$, at the point $x=a$, is

$$\left(x-a+\frac{\phi'a(1+\overline{\phi'a}^2)}{\phi''a}\right)^2+\left(y-\phi a-\frac{1+\overline{\phi'a}^2}{\phi''a}\right)=\frac{(1+\overline{\phi'a}^2)^3}{\overline{\phi''a}^2}$$

This circle cuts the curve, generally speaking: if not, as for example, at the vertices of an ellipse, it is evidence that the circle has a contact of some higher and odd order. The centre of the circle of curvature is a point on the normal, being that at which the normal touches the evolute. [INVOLUTE AND EVOLUTE.]

Not only is the term tangent most generally applied to the closest straight line only, but frequently only to that portion of the straight line which falls between the point of contact and the axis of x. Again, the normal is a straight line perpendicular to the tangent, drawn through the point of contact: but this term also is frequently applied only to that portion which falls between the point of contact and the axis of x. It is with reference to this limitation that the terms subtangent and subnormal are to be understood: the first meaning the distance from the foot of the tangent to the foot of the ordinate; the second that from the foot of the ordinate to that of the normal. The formula for the subtangent is $\phi a \div \phi' a$; that for the subnormal $\phi a \times \phi' a$.

Let β be the angle made by the tangent with the axis of x; usually the angle made by that part of the tangent which has positive ordinates with the positive side of the axis of x. Then β, at the point whose abscissa is x, is determined by the equation

$$\tan\beta=\frac{dy}{dx}; \text{ and subtangent} = y\frac{dx}{dy}, \text{ subnormal} = y\frac{dy}{dx}.$$

If we take the more general mode of measurement proposed in SIGN, this equation remains equally true. Now, keeping strictly to that mode, let β be the angle made by the tangent with the axis of x, θ the angle made by the radius vector r with the axis of x, and μ that made by the tangent with the radius vector. It will be found, then, that in all cases

$$\mu=\beta-\theta \quad , \quad \tan\mu=r\frac{d\theta}{dr}.$$

Unless the mode of attributing signs be carefully attended to, these last equations, though always considered as universally true, are not so in reality.

We now come to the consideration of a surface. The mode of defining contact of a given order resembles that adopted with reference to a curve. Thus if $z=\phi(x, y)$ and $z=\psi(x, y)$ be the equations of two surfaces coinciding when $x=a$, $y=b$, so that $\phi(a, b)=\psi(a, b)$, then if the point be taken at which $x=a+h$, $y=b+k$, the contact of the two surfaces is of the nth order, when the deflection

$$\phi(a+h, b+k)-\psi(a+h, b+k)$$

being developed in powers of h and k by Taylor's Theorem, shows no terms lower than those of the form $Ah^n+Bh^{n-1}k+\ldots+Mk^n$. This is tantamount to the following: two surfaces have a contact of the nth order when any plane whatever drawn through the point of contact cuts the surfaces in two curves which have a contact of the nth or a higher order.

Every surface has at every point a plane which has a complete contact of the first order. If $z=\phi(x, y)$, and x, y, z be the co-ordinates of the point of contact, and ξ, η, ζ those of any point in the tangent plane, then the equation of the tangent plane is

$$\zeta-z=\frac{dz}{dx}(\xi-x)+\frac{dz}{dy}(\eta-y).$$

But if the equation be given in the form $\phi(x, y, z)=0$, it is

$$\frac{d\phi}{dx}(\xi-x)+\frac{d\phi}{dy}(\eta-y)+\frac{d\phi}{dz}(\zeta-z)=0.$$

In the first case, the equations of the normal, a line drawn through the point of contact perpendicular to the tangent, are

$$\xi-x+\frac{dz}{dx}(\zeta-z)=0, \quad \eta-y+\frac{dz}{dy}(\zeta-z)=0.$$

In the latter case, they are

$$\frac{\xi-x}{\frac{d\phi}{dx}}=\frac{\eta-y}{\frac{d\phi}{dy}}=\frac{\zeta-z}{\frac{d\phi}{dz}}.$$

The tangent plane may 1. not cut the surface at all, as in a sphere: 2. coincide with the surface throughout a whole line, as in the cone or cylinder: 3. cut the surface, as in the case of an hyperboloid made by revolution of an hyperbola about the minor axis (the figure of a common dice-box). The criterion of distinction between these cases depends on the value of

$$\frac{d^2z}{dx^2}\cdot\frac{d^2z}{dy^2}-\left(\frac{d^2z}{dxdy}\right)^2, \text{ say U,}$$

at the point of contact. Imagine a plane to pass through the normal, cutting the surface in the curve (C) and the tangent plane in the straight line (L). Then, while the plane revolves about the normal, (L) is always tangent to (C).

I. Let U be positive. Then (L) has never more than a contact of the first order with (C), the surface nowhere passes through the tangent plane, and we have only such contact as is seen at any point of a sphere or ellipsoid.

2. Let U=0. Then (L) has never more than a contact of the first order with (C), except when the plane is in one position, in which there is a contact of a higher order. If U=0 at the point of contact only, and begin to take value at all adjacent points, nothing more would appear than in the last case, except that in one particular direction from the point of contact, and in its opposite, the surface would seem to grow nearer to the tangent plane than in any others. But if U=0 at all points of this surface, this approach to the tangent plane in one particular direction becomes more marked: for the surface lies on that plane in a straight line, that is to say, every tangent plane meets the surface in a straight line infinitely extended both ways; and the plane is tangent to the surface at every point of that straight line. Such surfaces, namely those in which U is always =0, are developable, or can be unrolled without any overlapping, rumpling, or tearing. Cones and cylinders are instances. Again, if U=0, not throughout the whole surface, but throughout one particular line upon it, that line will be a plane curve, and its plane will be tangent to the surface at every point in which it meets the surface.

3. Let U be negative. Then (L) has never more than a contact of the first order with (C), except in two different positions, in both of which there is contact of a higher order. Draw lines marking out these two positions of (L), and consequently dividing the tangent plane into four parts, with four angles round the point of contact. In one pair of the opposite angles, the surface lies on one side of the tangent plane, and in the other on the other.

Again, as the plane which revolves round the normal takes its different positions, the curvature of the section (C) changes. The two positions of the revolving plane in which the curvatures are greatest and least (algebraically) are at right angles to one another. We shall not enter into the mathematical formulæ connected with this subject, but shall only endeavour to give a popular illustration of this remarkable point.

Suppose an eggshell, unbroken, to be placed with either vertex uppermost. The descent will be equally rapid in all directions, or the curvature at the highest point of all the vertical sections will be the same. But suppose the shell to be so placed that some point intermediate between the two vertices is uppermost. The descent will not then be equally rapid in all directions, or the curvatures of the vertical sections will not be the same. The direction of most rapid descent will be at right angles to that of least rapid descent. The tangent plane has here a contact of the first of the three kinds above mentioned. If there be a contact of the second kind, all the circumstances are the same, except that the direction of least rapid descent gives, comparatively speaking, no descent at all at the first instant. If we take a cylinder, or other developable surface, and

make a tangent plane horizontal, there is absolutely no descent in one direction, or, by going along the tangent plane, we can remain entirely on the surface, in one certain direction, as before observed. And the direction of most rapid descent is at right angles to this direction of no descent.

To put a case of the third kind, suppose a saddle placed on a horse, and we take the lowest point of the seat. The tangent plane then cuts through the saddle horizontally. In some directions there is descent, in others ascent, with two directions in which there is, comparatively speaking, neither ascent nor descent. The direction of most rapid ascent, which is from the lowest point of the seat directly towards the head or tail of the animal, is at right angles to the direction of most rapid descent. Mathematically speaking, the curvatures of the vertical sections are sometimes positive, and sometimes negative, and the direction of the greatest negative (or algebraically least) curvature is at right angles to the direction of the greatest positive (or algebraically greatest) curvature.

As to points connected with the apparent physical character of the tangent, which have been in various places referred to this article, it will be more convenient to consider them under the word VELOCITY.

TANGHI'NIA, the name of a genus of plants belonging to the natural order Apocynaceæ. This name was given by Aubert du Petit Thouars to the plant which produces the celebrated Tanghin poison of Madagascar. The genus possesses an infundibuliform corolla, with a clavate tube, and 5-toothed throat: the anthers are subsessile; the fruit is a drupe, with a fibrous ligneous putamen or stone, which contains one or two seeds. The specific name T. venenifera was given to the plant which yields the poison. It has dense leaves, with erect branches, and paniculated terminal flowers. At the time Du Petit Thouars described this plant, he stated that it was closely allied to the Cerbera Manghas; and since its cultivation by Mr. Telfair in the Mauritius, there can be no doubt of its belonging to the genus Cerbera, and the plant is now called C. Tanghin. In its native island this plant attains the size of a tree, and has a hard wood which may be used for many kinds of carpentry. But the part which yields the poison is the kernel of the fruit. Although this kernel is small, not much larger than an almond, Mr. Telfair says that it contains enough poison to kill twenty persons. Its great use in Madagascar was as a means of trial, the innocent being supposed able to resist its action, whilst the guilty suffered under its influence. Radama, the late king of Madagascar, was desirous of abolishing its use, but found great difficulty in doing so on account of the prejudices of the natives. Mr. Telfair witnessed a sad instance of its use. The king Radama was taken ill, and got well by the use of mercury; but this medicine affected his mouth, so that the impression produced upon his 'skid,' or physician, was that the king had been poisoned. He therefore insisted that the Tanghin should be administered to himself and all the servants of the household, in order to ascertain the guilty party. The king protested against the procedure, but in vain. The whole household were shut up during the night without food, and in the morning were brought out for trial. The presiding 'skid,' or physician, then pounded the Tanghin bean to a pulp between two stones, and applied a small quantity to the back of the tongue of each individual. The effects varied in different individuals. In some it produced vomiting, and the poison being ejected from the stomach, they recovered. In others convulsions were brought on with violent efforts at vomiting, which soon destroyed life. (*Botanical Magazine*, fol. 2968.)

TANGIER. [MAROCCO.]

TANGLE. [SEA-WEEDS.]

TANGUT is the historical name of a country in Asia, which occupies the centre of the eastern, more extensive, and more elevated table-land of that continent [ASIA, vol. ii., p. 464], where a nation, which originally inhabited Tibet, and was called Tang, founded an empire in the seventh century, which was very powerful for a long time, and was overthrown by Genghis Khan in 1227. The country still goes by the name of Tangut, though at present a part of it is incorporated in the Chinese province of Kansi, whilst another is mostly in possession of two Mongol nations, the Olöth Tshoros and the Torbod Mongols.

Tangut borders on China Proper on the north-west, extending between 33° and 42° N. lat., and between 94° and 107° E. long. To the south of it is Tibet; to the west Chinese Turkistan, or the government of Thian-Shan Nanlu; and to the north Mongolia, of which also a portion is included within the lately erected province of Kansi. As the boundary-lines of the country are not politically determined, it is not possible to give an estimate of the area.

The southern portion of Tangut, or that which lies south of 38° N. lat., is one of the most mountainous tracts on the globe, and extends over the upper course of the river Hoang-ho and the basin of the lake of Khookhoo-nor. Along its southern border there is a very elevated range, which divides the upper courses of the rivers Hoang-ho and Yan-tse-kiang, and is called the Bayan Khara range. [BAYAN KHARA MOUNTAINS.] Another elevated range traverses the country in the same direction from east to west near 38° N. lat. This range rises at a short distance from the banks of the Hoang-ho north of the town of Lan-tcheou, and in its eastern part is called Kilian Shan; but farther west it takes the name of Nan Shan (or Southern Chain). It rises to a great elevation, especially towards the west, where many of their summits are covered with snow and united by extensive glaciers. This mountain-chain is supposed to be connected with the Kuenluen range near 92° E. long. These two ranges above mentioned occupy a great portion of the country between 33° and 38° N. lat., and nearly the whole of the remainder of the country is filled up by a third range, which connects these two ranges, and extends from south-east to north-west, being on the north united to the Nan Shan, and on the south to the Bayan Khara Mountians. This chain bears the name of Siue Shan, or Snowy range, on account of the numerous summits which rise above the snow-line. The river Hoang-ho breaks through this range, but the huge rocky masses compel the river to make a great bend towards the west between 34° and 36° N. lat., and the circuit which the river makes shows the immense extent of these masses of rock. In this part of its course the river is said to be hemmed in by lofty mountains, so that no communication can be established along the banks. Its course above this bend is very imperfectly known, and the fabulous accounts of its sources show that they have never been visited even by Chinese geographers. The river enters a wide valley by a narrow gorge formed by two very elevated mountains a little above the town of Ho-cheou (36° N. lat. and 102° E. long.). At the opening of this gorge is a fortress, called Tsy-shy-kuan.

Tangut is separated from China Proper by a fourth range, the mountains of Sifan, which run south and north, being connected at their southern extremity with the Bayan Khara Mountains and the Siue Shan by an extensive mountain-knot, which is in the country formerly called Sifan, whence the chain has obtained its name. Though this range is less elevated than the Siue Shan, it rises in several places above the snow-line, and occupies a considerable width. It is supposed to terminate near the banks of the Hoang-ho, a few miles south of 38° N. lat. Opposite to it and on the northern banks of the river rises another chain, which may be considered as the continuation of the mountains of Sifan; but this range, which continues along the western bank of the river as far north as 42° N. lat., rises only to a moderate elevation, and is stated to occupy in many places only three or four miles in width: it is called Holang Shan, and slopes on the west down into the steppe of the Olöth Tshoros. This range is distinguished from all the other ranges of Tangut by being thickly wooded on its eastern declivity.

Only a small portion of the countries enclosed by these mountain masses is fit for cultivation. It does not appear that there is any cultivation in the upper valley of the Hoang-ho above the fortress of Tsy-shy-kuan. Below that place and as far as Lan-tcheou, the valley is wider, and narrow tracts along the banks of the river are cultivated and fertile. This part of the valley is compared with that of the Adige in Tyrol. Farther down, and as far as the neighbourhood of Ning-hia, a town built on the western banks of the Hoang-ho, at the eastern declivity of the Holang Shan (38° 32′ N. lat.), the valley has not been visited by Europeans. At this place the river runs in a wide valley which has been rendered fertile by numerous canals, which are fed by the waters of the river, and in which rice is extensively cultivated. There are also numerous plantations of fruit-trees. The soil contains much saltpetre. The town of Ning-hia, the antient capital of Tangut, is of considerable extent, being fifteen li (equal to five miles) in cir-

emit. It has some very good manufactures of carpets and paper, and a considerable commerce with the nomadic tribes who wander about in the country west of the Holang Shan. Below the town of Ning-hia the valley of the Hoang-ho grows wider, as the range of the Holang-shan retires farther west, but its fertility decreases. About eighteen miles from Ning-hia the canals cease and no rice is cultivated. Other grain is still grown about 30 miles farther north, where the country gradually changes into a sandy, arid desert, interspersed with hills, swampy tracts, and pastures.

The lateral valley of Si-ning-tcheou opens to the Hoang-ho from the west above the town of Lan-tcheou between the Kilian Shan and the most elevated portion of the Siue Shan. The valley is not extensive, but appears to be fertile: it contains the town of Si-ning-tcheou, which is not quite as large as Ning-hia, but a much more commercial place, as the road which connects northern China with Hlassa in Tibet passes through it. This road leads from Si-ning-tcheou westward over a chain to the lake of Khookhoo-nor, which is of great but unknown extent. It is an alpine lake enclosed by high mountains, and has no outlet. The remainder of the road lies partly over numerous large mountain-masses, furrowed only by narrow glens and ravines, and partly over rocky and sandy tablelands, and the whole is described as a desert, in which only a small number of nomadic mountaineers are met with, and where the traveller for forty days' journey finds no other accommodation than the tents of the poor mountaineers. In spite of the difficulties, the road, as it appears, is much travelled, and the bazars of Si-ning-tcheou are well provided with provisions and articles of luxury. Even coffee and dates may be got there. This town is also the depôt of the Turkish rhubarb, which grows, as it appears, only on the more elevated parts of the Siue Shan and Kilian Shan, and is sent from Si-ning-tcheou to all parts of the world. Before the commerce between China and Siberia was established, this article was brought to Europe through Turkistan, Persia, and Turkey, and therefore is still called Turkey rhubarb, though at present it comes through Kiachta and Russia. When the Jesuits, who had been sent to these countries by the emperor Kang-hi, were at Si-ning-tcheou, they were astonished at seeing the quantity of rhubarb which, during the months of October and November, was daily brought from the adjacent mountains to the town.

The northern part of Tangut, with the exception of the valley of the Hoang-ho, is occupied by a wide desert plain, which constitutes a portion of the Gobi. [Gobi, vol. xi., p. 286.] The steep declivities of the Kilian and Nan Shan however do not come close to the desert, but are separated from it by a hilly tract from 30 to 50 miles wide, which contains some extensive tracts fit for cultivation, and in which some large towns have been built, as the great commercial route which connects China with the countries of Western Asia runs longitudinally through this hilly tract, and is confined to it by the extensive sandy desert on the north, and the still less practicable mountain-desert which bounds it on the south. According to our best information, the ranges of the Kilian Shan, and especially of the Nan Shan, are covered with eternal snow, and one would imagine that they give origin to rivers which bring down a great volume of water, but that is not the case. The volume of water is very moderate: a part of it is consumed in irrigating the adjacent fields, and the remainder is absorbed by the sandy soil, as soon as it reaches the plain, after having left the hilly tract. This evidently shows that the watershed of the mountains must be at a very moderate distance from the Gobi. The surface of the hilly tract consists of an alternation of high lands and of depressions, running from the mountains northward to the border of the desert. The high lands are of considerable extent, their upper surface broken and rocky, and only occasionally covered with a thin layer of earth unfit for the growth of trees. In general the rocks are bare. The depressions between these high grounds are less extensive, but exhibit a considerable degree of fertility where they are irrigated. Even in those parts which are beyond the reach of irrigation, they are chiefly cultivated. To protect this hilly region, and the great commercial road which runs through it, against the nomadic tribes of the Gobi, the Chinese have continued the Great Wall along its northern border westward to 98° E. long., and along the wall are built the fortresses which protect the line and the towns through which the road runs. The road leaves the valley of the Hoang-ho at the town of Lan-tcheou [China, vol. vii., p. 80], the capital of Kansi, and runs in a north-north-west direction over a stony and hilly country to the town of Liang-tcheou, a considerable place, of which however nothing is reported, except that the district in which it is situated is fertile, and contains a great number of villages. From Liang-tcheou the road runs north-west to Kan-tcheou-foo, a large and well-built town, which has many manufactures of woollen stuffs and felts, which articles are in great demand among the nomadic tribes of the Olöth Tshoros, who inhabit the contiguous part of the Gobi, and bring to the place their wool, horses, cattle, and sheep. It receives also large quantities of rhubarb from the Kilian Shan. From Kan-tcheou-foo the road continues in a north-west direction to So-tcheou, a large and well fortified town, with numerous bazars, well provided with provisions and manufactured articles. The town is divided into two sections, one of which is occupied by the Chinese, and the other by the foreign merchants from Bokhara and Turkistan. The latter is divided from the former by a separate wall, the gates of which are shut at night: in other respects foreigners do not experience any different treatment from natives. As So-tcheou is the last large place through which the caravans pass before they enter the desert between Tangut and Thian-shan-nahr: the commerce is very great, especially in provisions. About 50 or 60 miles west of So-tcheou is the most western gate of the Great Wall, called Kia-yu-kooan, or the gate of the You-stone (jasper), through which the caravans pass to enter the desert of Han-hai, which must be traversed in order to reach Hami in Thian-Shan-Nanlu. The last-mentioned town is 960 li, or 320 miles, from the gate of Kia-yu-kooan, and that is the width of the Gobi at this place, which is considered the narrowest part of it.

The towns hitherto noticed lie along the great caravan-road, but farther west the Chinese geographers mention other places of importance. The largest, as it seems, is Ngan-si-foo, a town of the first rank, and the capital of the whole district. North-west of it, and on the border of the desert, is the town of Yu-men-kiang, which is built near a pass between high hills, through which a road leads northward to Hami, of which we have no information. South-west of Ngan-si-foot are the towns of Toong-hooang-kiang, and Sha-tcheou. The last-mentioned place, whose name means Sandtown, seems to be the last inhabited place towards the west. It has not been visited by Europeans, except by Marco Polo, who describes it as rather a large place: he says that the inhabitants live on the produce of their fields and orchards, and have little commerce. From his account, and that of a Chinese traveller, it is evident that two roads run north-west and west from this place. Marco Polo reached it after traversing the desert of Lop, by a thirty days' journey, having departed from the town of Lop, which is on the banks of the lake of the same name. The intermediate tract was mostly covered with sand, but in some places the soil consisted of bare and broken rocks. A Chinese traveller departing from Sha-tcheou, and taking the western route, seems to have traversed a still worse country, until he reached the town of Khotan. [Thian-Shan-Nanlu.]

That portion of the Gobi which lies north of the Great Wall contains many tracts which are covered with grass, and supply pasture to the Olöth Tshoros, but others have a sandy or stony soil, and are quite barren. In some places there are extensive swamps, especially where the rivers are lost, which descend from the Kilian Shan, among which the Etzina probably runs more than 200 miles. But the Han Hai, or that portion which lies between the gate of Kia-yu-kooan and Hami, is nearly uninhabited, as water is rarely met with, and the grassy tracts are still less frequent. The sand with which the surface is covered is very fine, and frequently raised into the air by strong winds.

Our information respecting the climate of Tangut is very scanty. The cold in winter is intense, and lasts for several months. The Jesuits found the Hoang-ho near 40° N. lat., at the end of November, covered with thick ice, so that the caravan was able to pass over it, though the river was more than 300 yards wide. At Ning-hia a heavy fall of snow was experienced in the middle of April. In summer the heat is great, but much less than in the low countries of China; the climate is considered as extremely healthy.

We are no better acquainted with the productions of

Tangut. Every kind of grain is grown in the few tracts whose soil is fit for cultivation, and rice is raised where irrigation is practicable. The nomadic nations have numerous herds of camels, horses, and cattle, and large flocks of sheep and goats. In the mountain-region is found the yak or mountain-cow, whose tail gives the chowry. It is used for riding as a saddle-horse. In the desert are numerous wild animals, such as wild hogs, deer, the argali, and hares. It is also said that in the woods of the Holang Shan there are wild horses. Wild cattle are found on the declivity of the Kilian Shan. No mines are worked. In the desert some extensive tracts are covered with agates, cornelians, and other precious stones, which are collected by the nomadic tribes and sent to China.

The inhabitants of Tangut are a very mixed race. Mongol tribes inhabit the Gobi, and occupy also the mountain-ranges north of Lake Khookoo-nor, but the mountaineers who are in possession of the mountain-region south of Lake Khookoo-nor, derive their origin from Tibet. It is even supposed that in this part there may still exist small tribes of the Miotse and Yuet-shi, who are considered as the aborigines of this region, but have been nearly exterminated by the wars with their neighbours the Mongols and the inhabitants of Tibet. It is not known if that Turkish nation which is called Sobko, and which inhabits the western part of the Kuen-luen mountains [Tibet], extends over the western districts of Tangut. The agricultural population is mostly composed of Chinese and their descendants, among whom a small number of families of Turkish origin are settled. But in the towns the number of Turkish settlers seems to be considerable. They are Mohammedans, and there are mosques in the larger towns of Tangut, especially in those which lie along the caravan road. All the other inhabitants are Buddhists. In the time of Marco Polo there were also Nestorian Christians in the towns, but they have disappeared.

The Chinese emperors subjected the country of Tangut probably during the dynasty of Han, shortly before the birth of Christ, and maintained their authority over this and the countries farther west to the eighth century, in spite of their long protracted wars with the Hiongnu, a Turkish nation which then was in possession of the desert north of Tangut. In the middle of the seventh century they extended their dominion even over Western Turkistan to the eastern banks of the Caspian Sea. But in the eighth century Tangut was occupied by a nation of Tibetan origin, which founded in these parts the empire of Thufan; and though it was overthrown by the Chinese, and some Turkish tribes, their allies, in the ninth century, the Tibetans erected in the following century the empire of Tangut or Hia, which maintained its power till it was destroyed by Genghis Khan, in 1227, and by its overthrow the conqueror opened to his countrymen the road to China, of which they took possession a few years afterwards. With the downfall of the dynasty of the Mongols (1341), the best part of Tangut remained under the sway of the emperors of the dynasty of Ming, though the Mongols after their retreat from China had occupied the northern and more desert portion of it, where they maintained their independence to the end of the seventeenth century. In the wars of the Galdan of the Olöth [Songaria, vol. xxii., p. 245], a tribe of the Olöth Mongols expelled the Khalkas from the country west of the Hoang-ho, and took possession of it. But after the defeat of the Goldan, they submitted to the Chinese emperor in 1690, and since that time the whole of Tangut has been annexed to China. The Chinese government is very assiduous in promoting agriculture in Tangut, and in increasing the agricultural and commercial population, this being considered the most efficacious mode of restraining the nomadic tribes which inhabit the northern and southern districts of Tangut. To give to its measures greater stability and to forward their extension, it has converted the greater part of Tangut, with some of the adjacent countries, into a province of China Proper, under the name of Kansi. (Du Halde's *History of China;* Ritter's *Erdkunde von Asien*, vol. i.)

TANJORE, a district in Southern Hindustan, was formerly a small independent kingdom or principality, and though now under British superintendence, is still governed by its raja. The district is included in the province of the Carnatic and presidency of Madras: it is bounded on the east by the Bay of Bengal, and extends from Point Calymere, 10° 18′ N. lat., to the mouth of the Coleroon, 11° 25′ N. lat. To the north and west it is bounded by the Coleroon and the district of Trichinopoli; and to the south and west by the sea and the territory of the Polygars.

The river Cavery, near Trichinopoli, separates into two branches, of which the northern is called the Coleroon, and falls into the sea a little to the north of Devicotta; the southern branch retains its name of Cavery. These two streams however, after flowing about twenty miles at some distance, again approach each other, and are only prevented by a narrow neck of land from re-uniting and discharging the whole river by the channel of the Coleroon. To prevent this junction large mounds have been formed, and are kept in repair at a considerable expense. The Cavery, thus separated from the Coleroon, flows through the flat territory of Tanjore, and divides into a number of smaller streams, which are conducted into reservoirs and canals for the purpose of irrigation: by this means nearly the whole district, which would otherwise be a sandy desert, is rendered one of the most fertile in Hindustan. From Devicotta to the salt swamp near Point Calymere, and from the Bay of Bengal to the city of Tanjore, the whole country, with its rich covering of alluvial soil, has the appearance of a garden: from Tanjore to Trichinopoli it is like a desert.

The principal product of the district is rice, of which two crops are obtained annually; the next in importance is indigo: both are exported to Madras in considerable quantities, besides cocoa-nuts, grain, paddy, and lamp-oil.

The district of Tanjore has never been in the actual occupation of the Mohammedans. Its Hindu religious structures are therefore uninjured, and in no part of Hindustan are they so numerous, so large, and so imposing. There is hardly a village without its brick pagoda and lofty gateway. Almost all the principal offices are in the hands of the Brahmins, and they are also the chief landholders.

Besides the capital, Tanjore, the principal towns are the following:—Carrical, 10° 55′ N. lat., 79° 55′ E. long. Combooconam, 11° N. lat., 79° 25′ E. long., is the antient capital of the rajas of Tanjore: there are remains which indicate its former splendour, and its pagodas and tanks are still very fine: it is chiefly inhabited by Brahmins. Devicotta (*Devicata*, the fort of the goddess), 11° 20′ N. lat., 79° 55′ E. long. Nagore, 10° 49′ N. lat., 79° 55′ E. long., a sea-port with a considerable export and import trade. Negapatam. Tranquebar. The villages are numerous, and the population dense.

The antient sovereigns of Tanjore were the Chola dynasty, who probably gave to the whole district the name Chola Mandala (corrupted into Coromandel), the former term in Sanscrit signifying an orbit or circle, and thence a region or tract of country. The kingdom of Tanjore was wrested from its original Hindu sovereigns by the Mahratta chief Eccojee, the brother of Sevajee, in 1675. It has ever since been retained by the Mahratta race; so that, though the language of the inhabitants is Tamul, the language of the court is Mahratta. In 1771 a dispute broke out between Mohammed Ali, the nabob of the Carnatic, and Tuljajee, the raja of Tanjore, with respect to the keeping in repair the mounds which prevent the stream of the Cavery from falling into the Coleroon. The mounds are in the territory of Trichinopoli, and the nabob, as sovereign of that territory, claimed the right of repairing, and consequently of neglecting to repair, by which a portion of the nabob's territory might have been fertilized, and nearly the whole of Tanjore rendered a desert. The raja had been compelled to pay tribute to the nabob, but had never been subject to him, and appealed to the British to protect him in his right to repair, which had always been exercised by the rajas of Tanjore, and for which, he contended, he paid his tribute. The British however took the part of the nabob. On the 20th of August, 1773, the siege of the city of Tanjore was commenced, and a passage twelve feet wide having been completed across the wet ditch which surrounds the walls of the forts, on the 16th of September, when the sun was in the meridian and the raja's troops were taking repose, the British unexpectedly made the assault, and carried the fortress, with hardly any resistance, the raja and his family being taken prisoners. The raja was then made subject to the nabob; but in consequence of the disapprobation which these proceedings met with in England, on the 11th of April, 1776, the re-

storation of the raja to his former independence was proclaimed by the British. In 1799 the territory of Tanjore was subjected by treaty to British authority. The raja retains the forts of Tanjore, which are garrisoned by him, subject however to the condition of placing them in the hands of the British in case of war in the province. He has a clear allowance of a lac of rupees annually, and one-fifth of the surplus revenue of the territory, after payment of the civil and military establishments, which amounts to at least a lac more. He also retains his palaces, and also a tribute paid to him by Tranquebar.

The present raja is Sewajee, the son of Sarbojee, who was adopted by the previous raja Tuljajee, or Julia Maha, and who was intrusted by him at his death to the missionary Schwarz. Of the circumstances under which the sovereign power was ultimately obtained by Sarhojee from Ameer Sing, the half-brother of Tuljajee, an account is given in the article Schwartz.

(Hamilton's *East India Gazetteer;* Malcolm's *Travels in Hindustan and China in* 1836-7; Mill's *History of British India*, by H. H. Wilson.)

TANJORE, the capital of the district of Tanjore, in 10° 47′ N. lat. and 79° 13′ E. long., is about 40 miles east from Trichinopoli, and about 57 miles west from the Bay of Bengal, direct distances. The city is situated not far from the south bank of the Cavery, and is five or six miles in circumference, including the suburbs. It is a place of great strength, being defended by two forts, which are connected, and both are surrounded by walls built of large stones, and by broad and deep wet ditches. The city is in a flourishing state: it is regularly built, and is said to contain a larger proportion of good houses than any other town in Southern Hindustan. The population is probably not less than 70,000 or 80,000. The palace of the raja, where he resides, is in the larger fort: in one of the halls of audience is a colossal statue of Sarbojee, by Flaxman, which was executed by commission from Sarbojee himself. The pagodas of Tanjore are very large, with paved yards and extensive gardens: one of the largest in Hindustan is situated in the smaller fort: it contains a bull finely sculptured in black granite. The Protestant Mission church was built at the expense of the missionary Schwarz: it is a spacious and handsome structure, and has been thoroughly repaired by the present raja. Schwarz was buried behind the pulpit; the spot is marked by a slab, on which is an inscription in English poetry, ascribed to the raja Sarbojee. Service is performed in the church on Sundays both in Tamul and in English. The Protestant communicants belonging to the Tanjore mission amount to about 750, and there are also between 400 and 500 Roman Catholic converts, under priests who are chiefly Jesuits from Goa.

(Hamilton's *East India Gazetteer;* Malcolm's *Travels in Hindustan and China.*)

TANK, a reservoir for water or other fluids. The name is sometimes applied to large open receptacles, or ponds, formed by excavating the ground and disposing the removed earth in the form of banks to retain the water; but the tanks which will here be especially treated of are the smaller covered reservoirs used to collect and retain water and liquid manure for domestic and agricultural purposes. Respecting the construction of ponds it will be sufficient to refer to Embankment, vol. ix., p. 373, for the method of forming the retaining banks, and to Canal, vol. vi., p. 219, for a description of the process of *puddling* with clay, which is always necessary in forming a reservoir in a porous soil, unless the more expensive method of paving or lining with chalk, bricks, stone, or timber, be resorted to. See also Sluice, vol. xxii., p. 142, for a notice of the means used to regulate the drawing off of water from ponds, and to prevent accident from their becoming over-filled.

In high mountainous pastures, tanks are indispensable to supply both men and cattle with water; and they ought to be very carefully constructed of such materials as are at hand. In the pastures of the Jura, between France and Switzerland, the tanks are usually made of wood, in the following manner: a square excavation is made in the ground, which, if necessary, is lined with a coating of clay or impervious earth to prevent the escape of the water; fir-trees, deprived of their bark, are then laid close together and fastened with wooden pins, so as to form the floor, and the sides are lined in a similar manner. The tank is covered with a roof of the same materials; but this, instead of rising from the sides to a point or ridge, according to the form usually adopted in roofing, is made in the shape of an inverted hollow pyramid, so that it acts as a funnel to conduct all the rain-water which falls upon it into the tank, at the same time that it keeps the tank cool, and prevents evaporation. Such tanks are usually placed at a small distance from the habitation and cowhouse, if there be one; and the water from their roofs is conducted, in spouts made of small trees sawn in two and roughly hollowed out, to the funnelled roof of the tank. They are usually of a cubical form, from 15 to 20 feet square; but if a larger size be required, an oblong shape is preferred, the depth and width seldom exceeding 20 feet. After being once filled, these tanks seldom fail to afford an abundant supply of water, although, in summer, thirty or forty head of cattle may have to be supplied exclusively from them.

The importance of collecting rain-water for domestic purposes, especially in districts where springs are deficient or lie at a great depth, has been much overlooked in this country. Waistell, in the work referred to at the end of this article, urges the importance of placing spouts round all the buildings of a farm to collect the rain-water which falls upon them into a tank or tanks; observing that, besides the value of the supply of water thus obtained, the buildings will be benefited by the walls and foundations being kept drier than when the water from the roof is suffered to fall upon them. He states that the quantity of water that falls annually upon every hundred superficial feet or square of building (in Great Britain) is about 1400 imperial gallons; and this statement appears to be fully borne out by the observations recorded in the article Rain, vol. xix., p. 270. If therefore the external surfaces of roofs were adapted to the collection of the rain-water which falls upon them, and means were provided for conveying it to covered tanks, in which it might be preserved from evaporation, and kept free from any admixture of impurities, almost every house might be readily and cheaply supplied with a quantity of wholesome water sufficient for the ordinary wants of its inhabitants. The extensive roofs of churches and other public buildings might be employed in like way to collect water for the supply of ponds or tanks for public use. In some cases even the drainage of lands might also be made available, as the water may be submitted to any required process of filtration before it is allowed to enter the tank.

Tanks or cisterns to hold water for domestic purposes may be conveniently situated beneath the surface of the ground, so that, being paved over, they occupy no valuable space. They are formed of stone slabs grooved into each other and set in cement; of Welsh slate; of large paving-tiles bedded in cement; of brick-work; of plates of cast-iron; or of thick wooden planks, protected by charring and pitching, or lined with sheet-lead. The brick tanks described by Waistell are circular, the sides being built like a well, with bottoms of an inverted dome-shape, of very slight convexity. The top is also dome-shaped, and has an opening in the centre large enough to receive a man, in order that the tank may be thoroughly cleaned out when necessary. This opening, which may be upon the surface of the ground, or a little above it, should be covered with an oak flap pierced with a number of holes, or with an iron grating. The depth and width of the tank should, it is stated, be nearly equal. If necessary, a smaller brick chamber may be constructed alongside of the tank, in which the water may be filtered through gravel, sand, charcoal, &c. before entering it. It is recommended to make the opening by which water enters the tank near the top. Brick tanks of this description may be rendered water-tight by laying the inner course of bricks in cement, and plastering the whole of the inside with the same to the thickness of about three-quarters of an inch. To enable them without injury to bear the great weight of water when nearly full, the earth should be rammed closely round the brickwork, and it should be allowed to settle thoroughly before any great quantity of water is admitted. Loudon describes another kind of brick tank, contrived by Mr. Mallet to save expense in construction, by adopting a figure of maximum capacity and minimum surface. Mallet proposes, when the tank is large, to adopt the spherical form; and when of less than five or six feet in diameter, that of a short vertical cylinder with hemispherical ends. By puddling

with clay roundabout the tank, the necessity for the use of Roman cement is avoided.

In the forty-ninth volume of the 'Transactions' of the Society of Arts (part ii., p. 12), is a communication from Mrs. Davies Gilbert respecting a cheap method of constructing tanks for receiving water from the roofs of cottages, which has been successfully practised at Eastbourn, in Sussex. A reservoir having been dug seven feet deep and about the same wide, the bottom was covered with flints laid in liquid mortar composed of one measure of grey chalk lime (made of chalk marl) well beaten up with three measures of clean sea-sand. The side walls were built of the same materials, leaving a small space at the back of the wall, which space was filled up with the same sort of grout or liquid mortar. The tank was then roofed over with a dome, formed, without any centering, of smaller flints well bedded in mortar. A hole was left in the centre, and covered with a hood, within which was hung a pulley with a rope and bucket for drawing water from the tank. This account was published in 1833, and in 1837 an article appeared in the 'Labourers' Friend Magazine,' in which it is stated that such tanks had been found very useful during three dry summers. One, less than seven feet deep and wide, had supplied two labourers' families during that time, while most of the springs in the neighbourhood were dry. This paper describes a brick tank with sloping sides, the diameter at the base being smaller than at the top, and with a dome-shaped top formed by making each row of bricks project one-third beyond that immediately below it, and balancing the weight by filling up the back with earth as the work proceeds. One of the flint tanks, constructed as above described, at the Eastbourn workhouse, is twenty-three feet deep and eleven feet wide. Only ninety bushels of lime were allowed for its construction, including two coats of plaster, and the work was executed at ten shillings per hundred square feet.

In the article last quoted from, it is observed that a current of air has been supposed to promote the purity of the water preserved in tanks. If so, it may be easily provided for. Where the prevailing winds do not blow soot and leaves upon the roof, the water is found to remain good, even for drinking, without clearing out the rubbish more than once a year.

In addition to tanks for water, every farm-yard should have one to collect the liquid portion of the manure, which is washed by the rain through the refuse litter, and also the urine of the stalled cattle. Though not yet generally adopted in England, in France, Germany, and especially in Belgium, such tanks are considered as necessary to a farm as any of its most common buildings. They are usually constructed of an oblong shape, of brick well cemented, with one or more divisions, and capable of containing at least ten times as many hogsheads as there are heads of cattle on the farm. They are vaulted over, having a small aperture, in which a pump is placed, sufficient to allow a man occasionally to clear out the sediment, when the liquid has been pumped up. The best shape to contain a large quantity in the smallest space would be like those before described; but they cannot conveniently be made sufficiently large, and a cubical form, or rather that of several cubes in succession, is preferred. A tank for a farm of 200 acres of arable land should be 15 feet wide, 15 deep, and 45 long, giving 3 cubes of 15 feet, or a cavity capable of containing upwards of 10,000 cubic feet of liquid. In this tank the urine is diluted with water to prevent too rapid decomposition, and also to retain the ammonia which is formed; for which purpose gypsum and sulphate of copper are sometimes put into the tanks.

If the soil be not sandy, clay will answer instead of mortar to connect the brickwork, and a plastering of lime or cement will be sufficient to keep out the worms: but in very porous soils the bottom and sides must be puddled, to keep in the liquid; and it may be advantageous to build the walls in cement altogether. The liquid from the yards and stables is carried into the tank by a main drain constructed of brick or stone, and which receives a number of smaller drains from every part of the yards and cattle-sheds. Thus the litter in the yard is always dry, and none of the richness of the manure is lost by evaporation.

Sometimes the tank is vaulted like a cellar under the cow-house and stables, which are washed out twice every day, and all the dung and water are swept into a cess-pool communicating with the tank. Thus a very diluted, but rich liquid soon fills the first division of the tank: a sluice is then shut, and the next washings run into a second division, and when that is full, into a third. In the meantime the contents of the first tank have undergone a certain fermentation, by which the caustic ammonia first evolved has become mild and impregnates the water. It is then in a fit state to be carried on the land in tubs or water-carts. When properly diluted, it accelerates vegetation in a surprising degree; but if put on fresh, it burns the grass or any vegetable it touches, because the ammonia is in a caustic state. If a cow drop her urine in a field in a hot summer's day, all the grass it has touched becomes yellow and is burned up: but if the same happen in rainy weather, the spot soon becomes very green, and the grass luxuriant; because, in this case, the urine is amply diluted and its caustic nature corrected. Those who live near gas-works may collect the ammoniacal gas-water in a tank, and, by the addition of sulphuric acid in very small quantities, they may produce a very fertilising liquid, which will stimulate vegetation, and be a very good manure.

The necessary concomitant of a tank, whether for water or manure, is a water-cart, that is, a large cask put upon wheels to bring water from some distance. When there are no means of bringing water in pipes, a water-cart is quite indispensable. It is simply a cask placed on the frame of a cart, with a plug-hole in the end or lower part, from which the water may be let out by a cock, or drop on a flat board or into a bucket with holes, so as to spread it about. The plug-hole is shut by a valve inside, which can be opened by means of a string, the pressure of the liquid keeping it close to the plug-hole.

Many of the artificial manures, of which a number have been lately proposed, would make excellent liquids by merely mixing them up with water in a tank, and allowing a certain degree of fermentation to take place. Thus nothing is lost, and all volatile substances are taken up by the water. The soluble portions are dissolved and the earthy matters diffused, so as to be more equally spread over the land. If it be true that the ammonia found in some plants is chiefly derived from the very small portion discovered in rain water, it follows that a scarcely perceptible impregnation with this salt may have most powerful effects on vegetation.

When a farm-yard is situated on a hill, and there are fields or pastures on a lower level, at no great distance from it, the liquid from the tank may be conducted by channels lined with clay, having small sluices to direct the streams to any particular field. It may thus be made to irrigate temporarily a considerable surface, which it will greatly enrich. It may be led into the common furrows between the lands or stitches in ploughed land, and allowed to soak in them, and then it can be spread with the earth of the furrow, by means of broad shovels, over the growing crops, and will greatly invigorate them. This species of irrigation is common in Lombardy, where much ingenuity is shown in the manner in which water is made to flow in small rivulets between the rows of growing vegetables. The water here is supplied by streams, but the same method would distribute the tank-liquor with great effect. A very small quantity of this liquor, allowed to flow into the main feeder of a water-meadow, will soon prove how great effects are produced by impregnations which are scarcely perceptible by chemical analysis.

Small as the experience has hitherto been in this country of the advantages of liquid-manure tanks, it has sufficiently proved their use to induce every man who constructs a farm-yard and erects buildings to take in the tank as an essential part of his plan; and even if it only collected the refuse fluids which are allowed to run off in common sewers from most houses, it would soon repay the cost of its construction, while it rendered the ditches in the neighbourhood less subject to noxious emanations from the corrupted matter which now flows into them. The passage of air into or out of a manure-tank, and the consequent exhalation of noxious vapours, may be prevented by the use of air-traps, similar in principle to those described under SEWERS, vol. xxi., p. 319, at the points where the drains enter it.

The use of metallic cisterns or tanks, in lieu of wooden casks, for containing a supply of fresh water for long

voyages, is one of the great improvements effected of late years in naval economy. The nineteenth volume of the 'Transactions' of the Society of Arts contains an account of experiments on this subject, by General Samuel Bentham, in 1796 and the following years, the success of which induced the Society, in 1801, to present to him their gold medal. Large earthen jars have been tried for this purpose; but, while they keep the water very pure, they are not so convenient for general use as metallic tanks, which may be fitted to the shape of the vessel, so as to avoid any loss of room.

(Waistell's *Designs for Agricultural Buildings;* Loudon's *Encyclopædia of Cottage, Farm, and Villa Architecture; Transactions of the Society of Arts*, vols. xix. and xlix.; *Labourers' Friend Magazine*, 1837, p. 131.)

TANNAHILL, ROBERT, born at Paisley, in Scotland, on the 3rd of June, 1774, was the son of poor parents, by whom he was brought up to the occupation of a weaver, which he pursued in his native town and at Glasgow throughout the short period of his life. The earliest predilection of Tannahill was for poetry, and his taste was formed by the constant study of Allan Ramsay, Fergusson, and Burns. He failed to attain the spirit of these masters of Scottish song; but his pieces generally excel theirs in grace and sweetness. A specimen of this sweetness is found in his famous song, 'Gloomy winter's now awa':

'Tow'ring o'er the Newton woods,
Lavrocks fan the snaw-white clouds;
Siller saughs, wi' downie buds,
Adorn the banks sae brierie, O.
Round the sylvan fairy nooks
Feath'ry breckans fringe the rocks,
'Neath the brae the burnie jouks,
Ilka thing is cheerie, O.'

'Jessy, the flower of Dumblane,' is his best-known effort. The 'Song of the battle of Vittoria' has the merit of redeeming from the degradation of worthless words one of the finest airs of Scottish minstrelsy, and restoring it from a whistled jig to the solemn tone of a triumphal song.

His songs were commonly inspired by the immediate occasion; were the unlaboured fruit of his imagination or feelings. Besides the charm of harmony and of a perfect mastery of his language, which is almost exclusively Saxon, they derive not a little of their effect from the vein of desponding melancholy which runs through them. This melancholy was in some degree constitutional in Tannahill, but it was aggravated by the neglect of the world, and a hopelessness of ever raising himself above circumstances so unfavourable to genius as those in which fortune had thrown him. A kindred spirit, the Ettrick Shepherd, made a long pilgrimage to visit him at Paisley. After a night spent in the most delightful interchange of feeling, Mr. Hogg took his departure. 'Farewell, we shall never meet again,' were the words emphatically pronounced on this occasion by Tannahill, and their meaning was shortly afterwards explained. He committed suicide by drowning himself, in his thirty-sixth year. His remains are interred at Paisley.

Tannahill's songs were published in Paisley, in his lifetime, in a small volume. They are in every modern collection of Scottish melodies, and are occasionally printed (under Tannahill's name) with selections from Burns. For his life, see Chambers's *Scottish Biography*.

TANNER, THOMAS, was the eldest son of the Rev. Thomas Tanner, vicar of Market Lavington, Wiltshire, where he was born, 25th January, 1674. In November, 1689, he was entered a student of Queen's College, Oxford; but after having taken his degree of B.A., he removed in January, 1694, to All Souls, and he was elected a fellow of that society, 2nd Nov., 1696. So early as 1693, when he was only nineteen, he had published proposals for printing all the works of the antiquary John Leland, from the original manuscripts; but this design, which was afterwards partially executed by Hearne, did not receive such encouragement as to induce him to proceed with it. The reputation he had very early acquired for his knowledge of English antiquities may appear from the fact that Anthony à Wood, at his death in 1695, left his papers to Tanner's care. That same year Tanner published at London his first work, an 8vo. volume, entitled 'Notitia Monastica, or a Short Account of the Religious Houses in England and Wales.' Having taken orders, he was soon after appointed by Dr. Moore, bishop of Norwich, one of his chaplains; and having, in 1701, married Rose, the eldest daughter of that prelate, he received various preferments from his father-in-law; the chancellorship of Norwich about the time of his marriage; the office of commissary for the archdeaconry of Norfolk in 1703; that of commissary for the archdeaconry of Sudbury in 1707; and, in 1713, a prebend in the cathedral of Ely, to which diocese Moore had been by this time removed. Meanwhile Tanner's wife had died, at the age of twenty-five, in 1706. In the same year he was presented by a friend to the rectory of Thorp, near Norwich; and he then married Frances, daughter of Jacob Preston, Esq., of London, whom however he lost in 1718. His next publication, a new edition of Wood's 'Athenae Oxonienses,' enlarged by the addition of 500 new lives from Wood's manuscripts, appeared at London, in 2 vols. fol., in 1721. In December that year Tanner, who had taken his degree of D.D. in 1710, was appointed by Dr. Green, bishop of Norwich, to the archdeaconry of Norfolk; and in 1723 he resigned his prebend at Ely, and was appointed canon of Christ's Church, Oxford. He was consecrated to the bishopric of St. Asaph, in January, 1732; and in May, 1733, he married Mrs. Elizabeth Scottow of Thorp, receiving with her a fortune of 15,000*l.*; but he did not long enjoy these accessions of wealth and honour, his death taking place at Oxford on the 14th of December, 1735. By his second wife he left one son Thomas, who died rector of Hadley and Monks' Ely in Suffolk, and prebendary of Canterbury, in 1760. His widow married Robert Britiffe, Esq., M.P., and survived to 1771. A new edition of the 'Notitia Monastica,' with large additions (in part by the editor), was published in a folio volume at London, in 1744, by the bishop's brother, the Rev. John Tanner, vicar of Lowestoft in Suffolk; and a third edition, considerably improved, by the Rev. James Nasmith, appeared at Cambridge, in the same form, in 1787. The greater part of this last impression having been consumed in a fire which happened in Mr. Nichols's printing-house, on the night of Monday, the 8th of February, 1808, the book is very scarce. But Tanner's literary reputation rests principally on his great biographical and bibliographical work, entitled 'Bibliotheca Britannico-Hibernica, sive de Scriptoribus qui in Anglia, Scotia, et Hibernia, ad Saeculi xvii. initium floruerunt, literarum ordine, juxta familiarum nomina, dispositis, Commentarius,' which had been the labour of his leisure for forty years, and which was published, in folio, at London, in 1748, under the care of the Rev. Dr. David Wilkins. It is a work of extensive research and great general accuracy. Bishop Tanner had made large collections of charters, grants, deeds, and other instruments relating to the national antiquities, which he bequeathed to the Bodleian Library. Some letters from him are published in Dr. Bliss's collection of 'Letters written by Eminent Persons,' &c., 2 vols. 8vo., Lon., 1813. (*Biographia Britannica.*)

TANNIC ACID, or TANNIN, a peculiar vegetable acid existing in every part of the bark of each species of quercus, but especially in the bark: it is found however in the greatest quantity in the gall-nut. The name of this substance is derived from its property of combining with the skins of animals, or in tanning, by which they are rendered impervious to water, and prevented from putrefying.

To prepare tannic acid, galls are to be reduced to coarse powder, and digested in a percolator in æther which has been previously mixed and shaken with water: in the lower part of the vessel two strata of liquid appear, the heavier of which is a strong solution of tannic acid, by evaporating which, and by subsequent purification, the acid is obtained possessing the following properties:—It is a colourless or slightly yellowish mass, which does not crystallize, but resembles dried gum. It is readily soluble in water; the solution has an astringent but not a bitter taste; it reddens vegetable blues, and decomposes alkaline carbonates with effervescence; weak alcohol dissolves it, but æther only slightly; when the aqueous solution is exposed to the air, especially if the temperature be high, oxygen gas is absorbed, and an equal volume of carbonic acid gas evolved, while the tannic acid is converted into gallic and elagic acids. Tannic acid precipitates gelatin from solution; the compound has been called *tannogelatin*, and when the acid is in excess a viscid elastic mass is formed, which contains about half its weight of tannic acid; when the liquid from which the gelatin is pre-

cipitated is heated to ebullition, the tannogelatin is redissolved; tannic acid also precipitates albumen and starch.

When dried at 212° tannic acid consists of

Eighteen equivalents of carbon . .	108
Five equivalents of hydrogen . .	5
Nine equivalents of oxygen . .	72
Equivalent .	185
With Three equivalents of water .	27

When exposed to a temperature of 240°, the water is expelled.

Tannic acid combines with the alkalis to form salts, which are called *tannates*, and it precipitates most metallic oxides from solution. The salts of protoxide of iron suffer no change when a solution of tannic acid is added to them; but by exposure to the air a deep bluish-black precipitate is formed. Tannate of peroxide of iron, formed by the action of the acid on a persalt of the metal, is the basis of writing-ink, and is a black pulverulent precipitate.

TANNIN, ARTIFICIAL. It has been shown by Mr. Hatchett, that when powdered charcoal has been digested for a considerable time in dilute nitric acid, it is dissolved, and a reddish-coloured liquid is obtained, which by careful evaporation yields a brown glossy substance, amounting to about 120 parts from every 100 of charcoal employed.

The properties of this substance are that its taste is astringent and bitter, is soluble in water and in alcohol, and forms with a solution of gelatin an insoluble precipitate, consisting, according to Mr. Hatchett, of 36 of tannin and 64 of gelatin in 100 parts. Sulphuric acid and hydrochloric acid, when added to a solution of artificial tannin, occasion brown-coloured precipitates, which are soluble in hot water; the alkalis combine with this tannin, and it forms a precipitate of difficult solubility when added to lime, barytes, or strontia water, and also with most metallic solutions. These precipitates are of a brown colour; unlike natural tannin, the artificial resists the action of nitric acid.

When camphor and various resins, as shell-lac, benzoin, and dragon's blood are digested in sulphuric acid till it becomes black, a variety of artificial tannin is procured; when the blackened acid is poured into water, a black powder is deposited, which, by digestion in alcohol, furnishes a brown matter soluble in water, and forming an insoluble compound with gelatin.

Although in certain respects the above artificial substance agrees with tannic acid, yet the late discoveries as to the real nature of this principle tend to the opinion that the natural componnd is essentially different from the artificial.

TANNIN, PURE, or TANNIC ACID, *Medical Properties of*. This substance in combination with extractive has been long known under the name of tannin, and recognized as the active principle in almost all astringent vegetables. [Astringents.] As many of these are powerful in restraining excessive discharges, whether bloody or otherwise, it was conjectured that the pure principle would be yet more efficacious than when in a state of combination. Accordingly it has been administered in some passive hæmorrhages, chiefly from the uterus and the bronchial tubes. To effect any good it requires to be given for several days in small doses. It is with difficulty absorbed into the circulation, being with great reluctance taken up by the lacteals, and producing very great constipation, from its direct astringent action over the intestinal canal, with which it is brought into contact. Tannic acid has been recommended in cases of incurable organic diseases affecting the uterus, accompanied with wasting discharges. These it may for a time moderate, but the constipation induced never fails ultimately to aggravate the disease and discomfort of the patient. There is little therefore to induce practitioners to employ it.

TANNING is the process of converting the skins of animals into leather, by effecting a chemical combination between the gelatin of which they principally consist, and the astringent vegetable principle called *tannin*. [Bark, vol. iii., p. 456; Leather, vol. xiii., p. 379; and the preceding chemical articles on Tannin.] The object of the tanning process is to produce such a chemical change in skins as may render them, as observed by Dr. Ure, unalterable by the external agents which tend to decompose them in their natural state; and, in connection with the subsequent operations of dressing, or currying, to bring them into a state of pliability and impermeability to water which may adapt them for the many useful purposes to which leather is applied. Similar effects are produced by forcing oil or grease into the pores of the skin, or by preparation with alum; processes which may be briefly noticed in connection with the more immediate subject of this article.

The preparation of skins by tanning or other analogous processes has been practised from the earliest times; and, although it has engaged the attention of several scientific men, and has been the subject of many curious experiments, it has received less modification from recent improvements in chemical science than many other manufacturing processes. Several plans which have been suggested with a view to expediting the process, which, on the old system, is a very tedious one, have been found to deteriorate the quality of the leather, and have therefore been wholly or partially abandoned; and others, which appear to be more successful, are as yet adopted by a few manufacturers only. One of the probable causes of this comparatively slow progress of improvement in the leather manufacture is suggested in an interesting article on 'Tanning,' in the seventh edition of the 'Encyclopædia Britannica,' the author of which observes that, owing to the slow turning of money in consequence of the length of time occupied in tanning the heavier kinds of skins or hides, the tanner 'must have capital enough to pay for twelve months' hides, bark, &c., labour, and contingent expenses, besides keeping a stock of leather; and, when his capital has been turned at the end of twelve or more months, it must pay him, in one single profit, the interest, &c. of twelve months.' 'This,' he proceeds to say, 'has confined the trade to a few wealthy individuals, who look upon tanning as an investment for capital rather than as a business which might be improved by science; and, being in comfortable circumstances, they are not driven to personal exertion and close application, which would be required of less wealthy tradesmen.' 'It is,' he adds, 'from these circumstances, that tanning has been more stationary than any other manufacture, and that the few improvements which have been made in it have not been made by tanners.'

The larger and heavier skins operated upon by the tanner, as those of bulls, buffaloes, oxen, and cows, are technically distinguished as *hides;* while the name *skins* is applied to those of smaller animals, as calves, sheep, and goats. The process necessary to convert hides into the thick hard leather used for the soles of boots and shoes, and for similar purposes, will be first noticed. The hides are brought to the tanner either in a fresh state, when from animals recently slaughtered, or, when imported from other countries, dried or salted, and sometimes both, for the sake of preserving them from decomposition. In the former case the horns are removed, and the hide is scraped to cleanse it from any small portions of flesh or fatty matter which may adhere to the cutis; but in the latter it is necessary to soften the hides, and bring them as nearly as possible to the fresh state, by steeping them in water, and repeated rubbing or beating. After this the hair is removed; sometimes by steeping the hides for several days in a solution of lime and water, which has the effect of loosening the hair and epidermis, or outer skin; and sometimes by suspending them in a close chamber called a *smoke-house*, heated a little above the ordinary temperature of the atmosphere by means of a smouldering fire; in which case the epidermis becomes loosened by incipient putrefaction. In either case, when the hair and epidermis, or cuticle, are sufficiently loosened, they are removed by scraping with a curved knife, the hide being laid upon a convex bench, or 'beam.' The hides are prepared for the actual tanning, or immersion in a solution of bark, by steeping them for a few days in a pit containing a sour solution of rye or barley flour, or in a very weak menstruum consisting of one part of sulphuric acid mixed with from five hundred to a thousand parts of water. By this process, which is called 'raising,' the pores of the hides are distended and rendered more susceptible of the action of the tan, and the substance of the skin is apparently increased; but, as the process does not add to the gelatin of the skin, a hide which is much thickened by

the raising process loses its substance when condensed by the shoemaker's hammer.

Different tanners vary much in the details of the above-described preparatory processes, as well as in those which follow, and which constitute the actual tanning, or conversion of the prepared 'pelt' into leather. Oak bark is the substance most commonly used to supply the astringent principle, and it is crushed or ground to a coarse powder in a bark-mill. The comparative efficiency of this and other vegetable substances used for the same purpose is stated under BARK, vol. iii., p. 457. In the old method of tanning, which is not yet entirely abandoned, the hides and powdered bark were laid in alternate layers in the tan-pit, which was then filled with water to the brim. After some months the pit was emptied and re-filled with fresh bark and water, and this process was repeated whenever the strength of the bark was exhausted. In this way the time required for impregnating the hides varied, according to their thickness and other circumstances, from one to four years. The process has been greatly expedited by the improvements introduced in consequence of the experiments of M. Seguin, a French chemist, which are detailed in Nicholson's 'Journal,' vol. i., p. 271 (quarto series, published in the year 1797), of tanning with concentrated solutions of bark, formed by passing water through a mass of powdered bark, until, by successive infiltrations, it is completely deprived of its soluble tanning principle. Seguin expected that, by the use of very strong solutions, hides and skins might be tanned in as many days as, under the old system, they would require months; but these expectations have been very imperfectly realised in practice, although the new system, which has been very extensively adopted, has been productive of an important saving of time. Without entering into a minute investigation of the objections to the use of concentrated tanning infusions, it may be sufficient to state that, as observed by the late Sir Humphry Davy, in his valuable paper on the operation of astringent vegetables in tanning, published in the 'Philosophical Transactions' for 1803, experience shows that skins which are quickly tanned, by the use of strong solutions, produce leather of less durable quality than that which is slowly formed. Dr. Ure, in reference to this important point, says (*Dict. of Arts*, &c., p. 1226):—'The older tanners, who prided themselves on producing a substantial article, were so much impressed with the advantages of slowly impregnating skin with astringent matter, that they employed no concentrated infusion (ooze) in their pits, but stratified the skins with abundance of ground bark, and covered them with soft water, knowing that its active principles are very soluble, and that, by being gradually extracted, they would penetrate uniformly the whole of the animal fibres, instead of acting chiefly upon the surface, and making brittle leather, as the strong infusions never fail to do.' In illustration of these remarks, he states that 100lbs. of skin, quickly tanned in a strong infusion of bark, will produce 137lbs. of leather, while the same weight of skin, slowly tanned in a weak solution, produce only 117½lbs.; the additional 19½lbs. in the former case tending to swell the tanner's bill, although it deteriorates the leather, and causes it to contain less of the textile animal solid. Leather so highly charged with tannin is, moreover, so spongy as to allow moisture to pass readily through its pores; but the saving of time and increase of product are strong temptations to the tanner to adopt the system of tanning with concentrated infusions.

The variations of practice among different tanners extend to the substance used as an astringent, as well as to the manner of applying it. Ground oak-bark, which was formerly the only material in common use, and is still the most general, produces good leather of a light-fawn colour. Valonia, of which considerable quantities are imported for the use of tanners, produces leather of great solidity and weight, the colour of which is inclined to grey, and which, according to the 'Encyclopædia Britannica,' is more impervious to water than that made with oak-bark. Valonia consists of the acorns of the *Quercus Ægilops* [QUERCUS, vol. xlx., p. 214], and is brought from the Levant and the Morea. Catechu, or terra Japonica, the inspissated extract of the *Acacia Catechu* [CATECHU, vol. vi., p. 367], produces leather of a dark reddish fawn colour, which is light, spongy, and very pervious to water. Another substance which has been used of late years is a kind of bean-pod called divi-divi. These substances may be used either individually or in various combinations. In the methods of preparing tanning solutions there is also considerable variety. Some tanners use cold water for the purpose, and others hot water or steam; others again, instead of pure water, employ ooze, or tanning liquid, which has been exhausted by use. A further point of difference is found in the strength of the solutions used, which vary exceedingly. When the impregnation of the hides with tannin is effected by laying them flat in the tan-pits, they are frequently taken out to renew the solution; and the skins which have lain near the top of one pit are laid near the bottom of the next, so as to equalize the amount of hydrostatic pressure. Sometimes the tanning is facilitated by suspending the skins vertically in the liquid, by which means they are penetrated quickly; but the plan requires considerable room; and, unless the skins are frequently moved, it occasions injurious folds in the leather. Another plan, which answers well for small light skins, that require but a short time for tanning, is to sew up the skin into the form of a bag, to fill it with tan-liquor, and then immerse it in the pit. The great space required is the principal objection to this plan. In whichever of the above ways the tanning is effected, the hide is subjected to the action of solutions increasing progressively in strength, until it is so perfectly penetrated, that when cut through it presents a uniform brown colour; any appearance of a light streak in the middle of its thickness being an indication of imperfect tanning. When the process is complete, the hides are hung up in a shed, and allowed to dry slowly; and, while they are drying, they are compressed by beating or rubbing, or by passing them between rollers, to give them firmness and density. A yellow deposit is now found upon the surface of the leather, to which the name of 'bloom' or 'pitching' is technically given; and, although this deposit is subsequently removed by the shoemaker in the operation of buffing, and forms a useless addition to the weight and cost of the leather, the prejudice of purchasers requires that it be left on the surface by the tanner. According to the explanation of the 'Encyclopædia Britannica,' this bloom consists of the finer portion of the gelatin from the interior of the skin, dissolved by the exhausted ooze which remains upon the surface by capillary attraction; and the waste and deterioration occasioned by its formation should be prevented by the careful removal, by pressure, of the exhausted ooze.

Although, owing to the many differences in the practice of tanning, no definite time can be stated for the various operations mentioned above, it may be observed that the usual period required for tanning such hides as are used for the soles of men's boots is from six to twelve months, and that from fifteen to eighteen months are required in preparing those of the thickest kinds, which are termed 'butts' or 'backs.' It remains, before noticing the processes of preparing the thinner kinds of leather, to advert to some of the methods which have been contrived for effecting a greater saving of time than could be accomplished by any of those previously mentioned.

Several schemes have been devised for forcing a tanning solution through the pores of the hide by mechanical pressure. Mr. Francis Spilsbury obtained a patent in 1823 for effecting this object in the following manner:—The hides, after being freed from hair, cleansed, and otherwise prepared in the usual manner, were to be carefully examined as to soundness, any accidental hole being then sewed up, so as to make the skin water-tight. Three frames were to be provided of similar shape, and of such a form and size that when laid upon each other, with two hides placed between them, the frames might be screwed together by bolts passing through projecting ears, so that the whole should form a flat water-tight chamber, circumscribed by the middle frame. This apparatus being then placed in a vertical position, tan-liquor was introduced into the chamber or cavity between the hides through a pipe inserted in the centre frame; the air being allowed to escape by another pipe, which should be closed as soon as the chamber became filled with the liquid. The tan-liquor being supplied from an elevated cistern, any required degree of hydrostatic pressure might be produced in the chamber;

the effect of which was to distend or swell out the sides, and to force the liquid through the pores of the skins, it making its appearance on the outer sides like drops of dew or perspiration. When the leather appeared to be sufficiently tanned, the liquor was drawn off by a stop-cock, the frames were unscrewed, and the compressed edges of the hide were cut off. Spilsbury's process was soon abandoned; the reason of its failure being, according to the author before quoted, in the 'Encyclopædia Britannica,' that a large excess of tannin dissolves gelatin; so that tannate of gelatin was found on the outer sides of the skins in the form of long masses of slime, while the leather had lost much in weight, was very porous, and unequally tanned, in consequence of the tan-liquor penetrating most readily the thinnest or weakest parts of the hide. The error of the principle of this method not being generally understood, several similar plans were subsequently contrived by different persons; but these, or most of them, have been found unsuccessful. Of these, allusion may be made to the process patented by Mr. Drake, which consisted in sewing two skins together (after they had received a slight tanning in the ordinary way), so as to form a water-tight bag, which was filled with tan-liquor. The bag thus formed was compressed between two vertical gridiron-like frames or racks, by which it was prevented from bulging at the sides, and the liquor was confined to a thin vertical stratum. As in the last process, the aqueous portion of the tan-liquor percolated through the hides; and this penetration of the leather was facilitated by heating the room so as to promote evaporation from the exterior surfaces of the bags or skins. To prevent the bars of the racks or frames from producing permanent indentations in the leather, it is necessary to shift the bags a little occasionally during the process. In another somewhat similar plan, contrived by Mr. Cox, the hides were to be sewed up in the form of bags, and supported by a casing of canvas; and in the process of Mr. Chaplin, the bags were laid in an inclined position, and turned periodically to equalize the action of the tan. With every precaution however, it is difficult to tan a hide equally by any such process; and the objection urged against Spilsbury's plan applies to all the modifications of it. In another plan, which has been tried under several forms, the tanning liquid is applied to both sides of the hides, which are placed in an air-tight vessel, and is forced into their pores by hydrostatic pressure, the air being previously pumped out. The operation may be repeated as often as necessary, with infusions gradually increasing in strength; air being allowed to fill the pores of the hide between each immersion. Another plan which may be alluded to here is that of an American tanner, Osmond Cagswell, described by Hebert (*Engineer's and Mechanic's Encyclopædia*, vol. ii., p. 64), from the 'Journal' of the Franklin Institute. It consists in laying the hides upon a quantity of sawdust, contained in shallow boxes, of which any required number may be arranged in a suitable framework, about twelve inches above one another. The hides are not laid flat, but have their edges a little raised, so that their upper surfaces form shallow troughs capable of holding a layer of the tanning solution, which must be replenished from time to time as it filters through the hide and the sawdust, or other soft porous substance upon which it is laid. The spent liquor runs off from the bottom of the box or trough, which is somewhat inclined for that purpose, into a vessel or channel provided for it. 'The improvement consists,' according to the specification quoted by Hebert, 'in applying a solution of oak or other bark to hides or skins in such manner as that when the glutinous (gelatinous) particles of the hide have absorbed and become mixed with the tanning or astringent principle, the other part of the solution (*i. e.* the water) may pass off, and leave the hide free to receive more of the solution; and so on till it is tanned.' The operation was performed, it is stated, in a very short time; but as the outer parts or edges of the hides were not perfectly tanned by it, it was necessary to immerse them in vats in the usual manner for three or four weeks, to complete the process. If the principle were found to be advantageous, this, which forms a great defect in Mr. Cagswell's scheme, might be readily avoided.

Still more recent than any of the above-mentioned plans is that patented by Messrs. Herepath and Cox, of Bristol; which, as far as present experience can show, appears to effect the desired object very completely. Their process, which was patented November 16, 1837, is founded upon the principle of washing a sponge, by alternately allowing it to imbibe water, and then forcibly expressing it. In the old system of tanning, the hide may be compared to a sponge, which, after being saturated in a weak solution, is removed to a stronger, without the fluid contained in its pores being squeezed out; while in the new plan the weak infusion, or ooze, is forced out of the pores of the hide before it is subjected to a stronger, so that the fresh ooze may be able to act more efficiently. This is effected by connecting a number of hides together by strings, so as to form a continuous belt, and passing them between rollers turned by steam or other power, while they are being removed from one solution to another. In order to produce a tolerably uniform belt or continuous sheet of hides, they are either placed alternately head to head and tail to tail; or, if laid across the belt, with the heads and tails towards each side alternately. In one of the arrangements described in the specification, the hides are united into an endless band, and are always passed between the rollers (of which a pair is erected over each pit) in one direction; but in another plan the ends of the belt are not connected together, and the motion of the rollers is reversed when necessary, so that the belt of hides may be delivered into the tan-liquor alternately on each side of the apparatus. The latter arrangement is that described in the recently published article in the 'Encyclopædia Britannica,' from which the following details are derived. The lower roller is about thirty inches in diameter, and is covered with horsehair cloth; and the upper roller, which is pressed against the lower one with any determinate degree of force by means of weighted levers, is only about eighteen inches in diameter, and is covered with woollen cloth. By this process a strong hide may, it is stated, be tanned through in from one to two months, and calf-skins and *kips* (the hides of young cattle) in from twenty to thirty days. Double the usual quantity of work is performed; one-half of the capital required in the common process is rendered unnecessary; the saving on bark, labour, and general cost of manufacture is about 1½*d.* per lb.; and the increase in the weight of butt leather, as compared with that made in the usual way, is as 34 lbs. to 28 lbs. The very thick hides, known as 'butts,' when prepared by the patent process, are sent to market within four months from the time of their delivery in the tanner's yard; and the profits arising from quick returns, great weight of leather produced, and reduced cost of production, are stated to be eight times as great as upon the old plan, the prices of hides, bark, and leather being the same. It should be further observed that the leather made in this way is more elastic and impervious to water than any other.

Although the general principles involved in the preparation of all kinds of leather are the same, and some of the processes above described are performed with little variation upon the skins of smaller animals as well as upon the thick hides of various kinds of oxen, the precise course of operations requires many modifications which cannot be here described. Of the preparation of several of the lighter and more ornamental kinds of leather, a familiar account is given in No. 652 of the 'Penny Magazine,' which is devoted to a sketch of the processes followed at one of the great leather-manufactories of Bermondsey. We have hitherto alluded chiefly to the preparation of the thick hides used for sole-leather, among which several varieties may be found, each distinguished by a different technical name, by which its thickness, quality, or mode of preparation is known; but the thinnest and weakest hides, as well as the skins of calves and other animals, are also prepared for use as upper-leathers, in which case it is necessary to reduce their thickness by shaving or paring them down upon the flesh or inner side, before they are subjected to the action of the tanning infusions. Such hides or skins also require, after leaving the hands of the tanner, to be rubbed, softened, and dressed by the currier, in order to bring them to the necessary degree of flexibility and smoothness. The currier also has recourse to shaving or paring with a peculiarly formed knife, to bring the skin to the requisite tenuity; and it is his office to blacken the surface, which, for common shoe-leather, is done on the flesh side, although for some purposes leather is blackened upon the outer or *grain* side. Horse-hides, which are comparatively weak and thin, are sometimes

dressed in the latter way, under the name of *cordovan* hides, from the circumstance of such leather having been formerly made at Cordova in Spain. Calf-skins supply the quality of leather most generally preferred for the upper part of boots and shoes.

Of the thin skins prepared for ornamental purposes, many are tanned with a substance called sumach, prepared from a plant of the same name. [Rhus, vol. xix., p. 484.] At the establishment above referred to, which is commonly known as the Neckinger Mills, sumach leather is extensively prepared; the most important kind being that called 'Morocco,' which is made from goat-skins. In the routine of operations described in the paper from which we quote, the processes of cleansing the skins from fleshy impurities, and removing the hair, &c., present no material variation from those before described. During these processes, the lime employed to assist in the depilation enters the pores of the skin so completely, that it would impede the action of the tanning liquid if allowed to remain. It is therefore removed by immersion in an alkaline solution, which opens the pores in a way resembling the process of 'raising,' described in a previous column. The tanning is then performed by sewing up each skin into the form of a bag, with the grain or hair-side outwards, and nearly filling it with a strong solution of sumach in water. The bag is then fully distended by blowing into it, and the aperture is tied up; after which it is thrown into a large shallow vessel filled with hot water containing a little sumach. The distended bags float in this vessel, and are occasionally moved about with a wooden instrument, until the solution which they contain has thoroughly penetrated their substance. Owing to the thinness of the skins and the heat to which they are exposed, this operation is performed in a few hours. The process is expedited by taking the bags out of the solution and piling them upon a perforated bench or rack at the side of the tub, so that their own weight may force the confined liquid through the pores. When the tanning is completed, the bags are opened to remove the sediment of the sumach; the skins are washed, rubbed on a board, and dried; after which they are ready for dyeing and finishing with a ridged instrument, which imparts to the surface that peculiar grain by which morocco leather is distinguished. An inferior kind of leather, known as 'imitation morocco,' is prepared in a similar manner from sheep-skins. The wool is removed from these skins by the fellmonger; after which they are subjected to great pressure in a hydrostatic press, in order to remove the oleaginous or greasy matter which they contain in a much larger quantity than goat-skins. Surprising as it may appear, these, as well as larger and thicker skins, are often divided or split by a machine into two thicknesses, each of which may be made into leather suitable for some of the purposes to which it is applied, as the covering or lining of books, work-boxes, hats, &c.

Tawing is the name applied to the process by which the skins of sheep, lambs, and kids are converted into soft leather by the action of alum. Of this kind of leather gloves are usually made. Skins intended for tawing pass through a series of operations resembling those by which skins are prepared for tanning, but they are then subjected to a solution of alum and salt, to which, for the superior kinds of leather, flour and yolks of eggs are added, instead of a vegetable astringent solution. Sometimes the skins are put into a kind of barrel with the solution, and then the whole is made to rotate rapidly, by which the skins are quickly penetrated; and in other cases the impregnation is effected in an open tub, the skins being worked in the pasty liquid with the hands, or trampled upon by the naked feet of a man, until the emulsion is thoroughly incorporated with them. They subsequently require a good deal of stretching and rubbing over a kind of blunt-edged knife, and some other finishing operations, to give them the requisite smoothness and suppleness. Many of the gloves sold as kid are really made of lamb-skins, of which considerable numbers are imported from the shores of the Mediterranean. These are brought with the wool on; and, as it would be injured by the action of lime, it is loosened by inducing fermentation or incipient putrefaction in subterranean vaults or cellars; an operation which requires great nicety, since the pelt would be injured by allowing the fermentation to proceed too far. After the wool has been removed, and the skins have been scraped to free them from a slimy substance which exudes from the pores, the pelts are immersed in lime-water for a few days, to remove the grease which yet remains in them. The subsequent operations of removing the lime, tawing, &c., are similar to those required for other skins. In tawing sheep-skins with the wool on, for housings and similar articles, the wool side is carefully folded inwards, to protect it from the tawing liquid or paste, which is then applied to the flesh side only. Other skins are occasionally converted into leather without removing the wool or hair.

The only other kind of leather to be here noticed is that in which oil or grease is forced into the pores of the skin, to take the place of the animal matter, which would tend to its decomposition by putrefaction. This kind of leather takes its name from a fine soft leather prepared from the skin of the chamois goat; and the process by which it is made is called shamoying or shammying. Such leather was formerly very much used as an article of clothing, especially by soldiers; and it is still applied to several useful purposes, for which its peculiar softness and pliability renders it valuable. Wash-leather may be cited as a common example of this kind of preparation. The skins of deer, goats, sheep, &c. are dressed in this way; and much shamoyed leather is made from the inferior or least regular portion of split skins, in cases where the grain side has been taken off carefully of a uniform thickness for preparation in a different way. In general, when whole skins are shamoyed, the grain surface is removed by scraping or rubbing with pumice-stone. After the usual preparation with lime-water, and subsequent washing in a sour infusion of bran or some similar liquor, to remove the lime and open the pores, the skins are made as dry as possible by wringing or pressing them, and, in the process practised at the Neckinger Mills, are then exposed to the action of fulling-stocks, which consist of heavy wooden hammers, faced with copper, and set in motion by connection with a revolving shaft. A wheel revolves near the head of each hammer, of which two are mounted together in one framework; and this wheel is made, during its revolution, alternately to raise the hammer about a foot, and to let it fall into a trough fitted to receive its head. The leather, or rather a roll of the skins which are to be made into leather, is placed in this trough, and beaten by the hammers until it is perfectly dry. Cod-oil is then poured upon the skins, and forced into their pores by the action of the hammers or stocks; the form of the trough being such that the skins gradually turn themselves over and over during the operation, to render the beating uniform. When the oil is thoroughly beaten in, the skins are hung up to dry, after which they are returned to the trough to receive a fresh supply of oil and a repetition of the beating. This is repeated eight or nine times, until two or three gallons of oil have been imbibed by one hundred skins; and when they are sufficiently impregnated with it, they are placed in large tubs, or hung up in close heated chambers, in which they undergo a kind of fermentation, by which the pores are distended, and the action of the oil upon the fibres is completed; and finally they are immersed in a weak solution of potash, which removes whatever excess of oil may have remained in the leather, forming with it a saponaceous mixture. They are then hung up in the open air to dry.

(Dr. Ure's *Dictionary of Arts*, &c., art. 'Leather;' *Encyclopædia Britannica*, seventh edit., art. 'Tanning;' Hebert's *Engineer's and Mechanic's Encyclopædia*, art. 'Leather;' *Penny Magazine*, No. 652.)

TANSI'LLO, LUIGI, born of a noble family at Nola, in the kingdom of Naples, about the year 1510, wrote in his youth a licentious poem, entitled 'Il Vendemmiatore,' or 'the Vintager,' wherein he deals largely in the obscene jokes and scurrilities in which the peasantry of his country indulge during the vintage season, something after the manner of the antient Saturnalia. This poem, which the author did not intend for the press, was published by some friend through an abuse of confidence. In order to make amends, Tansillo wrote a pious poem, entitled 'Le Lagrime di San Pietro,' of which a part only was published before his death. A more complete edition of it was published in 1606. Malherbe made a translation, or rather wrote an imitation of it, entitled 'Les Larmes de St. Pierre, imitées du Tansille, au Roi Henri III.,' 1587. Tansillo resided chiefly at Naples, at the court of the Spanish viceroy

Don Pedro de Toledo and his son Don Garcia. He accompanied the viceroy in an expedition against the Barbary powers. He died about 1584. He wrote also a georgical poem, entitled 'Il Podere,' and another didactic poem, entitled 'La Balia,' besides sonnets, canzoni, and other lyric poems, in which he has displayed great poetical powers. He has been compared by some with Petrarca. A complete edition of Tansillo's works was published at Venice in 1738, in 4to. (Tiraboschi, *Storia della Letteratura Italiana;* Corniani, *Secoli della Letteratura Italiana.*)

TANSY. [TANACETUM.]

TANTA'LIDÆ, a family of Wading Birds. [GRALLATORES.]

The genus *Tantalus* of Linnæus stands between the genera *Ardea* and *Scolopax*, in the twelfth edition of the *Systema Naturæ*.

Cuvier places the genus *Tantalus* between the *Open-beaks* (*Hians*, Laeép.; *Anastomus*, Ill.) and the *Spoonbills* (*Platalea*, Linn.). He characterizes the genus as having the feet, the nostrils, and the bill of a stork; but the back of the bill is, he observes, rounded, and its point curved downwards and slightly notched on each side: a portion of the head, and sometimes of the neck, is, he adds, denuded of feathers. He notices the following species: the American Tantalus, *Tantalus loculator*, Linn.; the African Tantalus, *Tantalus Ibis*, Linn.; and the Ceylonese Ibis, *Tantalus leucocephalus*, the largest of all.

Of *Tantalus Ibis*, he remarks that it is white slightly clouded with purple on the wings, with a yellow beak, and the skin of the face naked and red, adding that it was for a long time regarded by naturalists as the bird so much revered by the antient Egyptians under the name of *Ibis*, but that recent researches had proved that the Ibis is a much smaller species, of which he intends to treat hereafter. This species, he states, is not commonly found in Egypt, but that it had been brought from Senegal. *Tantalus* he arranges in the family *Cultirostres*.

Ibis, Cuv., finds a place in the *Règne Animal*, as the second genus of Cuvier's *Longirostres*, between *Scolopax* and *Numenius*, Cuv.

Ibis religiosa, Cuv.—Adult.

Cuvier states that he has separated the Ibises from the *Tantali* of Gmelin, because their bill, arched like that of the *Tantali*, is nevertheless much more feeble, and without any notch at the point, whilst the nostrils, pierced towards the back of its base, are each prolonged into a furrow which continues to the tip. The bill, he adds, is rather thick, and nearly square at its base: there is always, he further remarks, some part of the head, or even of the neck, denuded of feathers. The external toes are notably palmated at their base, and the hind toe is sufficiently long to touch the earth. Some of the species, he observes, have the legs short and reticulated: these are the most robust, and have the largest bill.

Of this genus Cuvier notices the following species:—

L'Ibis sacrè (*Ibis religiosa*, Cuv.; *Abou-Hannes*, Bruce, pl. 35; *Tantalus Æthiopicus*, Lath.). For the adult of this species he refers to *Ossemens Fossiles*, tom. i., pl. 1 and 2 (skeleton and perfect bird); and for the young to Savigny, *Descrip. de l'Egypte*, *Hist. Nat. des Ois.*, pl. 7.

'This,' says Cuvier, 'is the most celebrated species: it was reared in the temples of antient Egypt, with veneration which approached to worship; and it was embalmed after its death, as some said, because it devoured the serpents which would otherwise have become dangerous to the country:—according to others, because there was a resemblance between its plumage and some of the phases of the moon: finally, according to other some, because its advent announced the rising of the Nile. For a long time it was thought that this Ibis of the Egyptians was the Tantalus of Africa: we now know that it belongs to the genus of which we are treating. It is as large as a hen, with white plumage, except the end of the wing-feathers, which is black; the last coverts have their barbs elongated, loose, black, with violet reflections, and thus covering the end of the wings and tail. The bill and the feet are black, as well as all the naked part of the head and neck: this part is covered in youth, at least on its upper surface, with small blackish feathers. The species is found throughout the extent of Africa.' [ABOU-HANNES.]

The other species noticed by Cuvier are—*L'Ibis rouge* (*Scolopax rubcr*, Linn.; *Tantalus rubcr*, Gm.) and *L'Ibis vert*, vulg. *Courlis vert* (*Scolopax falcinellus*, Linn.). (*Règne Animal.*)

The following is the description of *L'Ibis vert* (*Ibis falcinellus*):—Purpled chestnut, with deep green mantle. The young with the head and neck sprinkled with whitish. *Locality*, South of Europe and North of Africa. (*Règne Animal.*)

This, Cuvier observes, is to all appearance the species which the antients called the *Black Ibis*. [ABOU-HANNES, vol. i., p. 38.]

The views of Mr. Vigors with regard to the position of *Tantalus* will be found in the article HERONS, vol. xii., p. 165.

Mr. Swainson states that the *Tantalidæ*, or Ibises, are large and very singular birds, living almost entirely on the swampy banks of rivers and fresh waters, rarely, if ever frequenting open shores, like the more typical waders. He observes that their habits and structure seem compounded of those belonging to the HERONS on one side and to the *Rails* [RALLIDÆ] on the other: their flight and size, he says, remind us of the former, while their long toes and insectivorous nature are more in unison with the latter. He traces their analogy to the *Tenuirostres* in the metallic colours of their plumage and in their having their heads frequently bare of feathers, as in the *Ampelidæ* and other tenuirostral types. The majority, he remarks, live in tropical latitudes.

In the *Synopsis* the following characters of the family (which is placed between the *Ardeidæ* and *Rallidæ*) are given:—

Tantalidæ.

Family Character.—Size large. Bill hard, considerably lengthened, cylindrical, and curved from the base. Face and head more or less naked. Hinder toe on the same plane as the others. Plumage metallic.

Genera.

Anastomus, Ill. *Open beak.* Bill straight, hard, heavy, solid, compressed, marked with longitudinal wrinkles. Upper mandible very straight; the base thickened at the top and as high as the crown; the tip notched; the margin dentated: under mandible greatly curved upwards, and only touching the upper at the base and at the tip.

Example, *Anastomus lamelligerus.*

Tantalus, Linn. Bill nearly as thick at the base as the head; cylindrical and attenuated towards the tips, which are slender and slightly bent: margins entire. Upper mandible notched. Nostrils naked, vertical, basal, oval-oblong. Toes connected at the base.

Example, *Tantalus loculator.*

Ibis, Antiq. Bill much more slender; cylindrical, and arched from the base. Nostrils basal, lateral. Wings broad, ample: the second and third quills longest.

Example, *Ibis ruber*,

Aramus, Vieill. Bill lengthened, slightly curved towards the point, which is entire and inflexed. Under mandible curved from about the middle and angulated. Furrow of the nostrils long. Nostrils lateral, remote from the base, longitudinal. Feet long. Hallux elevated. Anterior toes divided at their base. Wings moderate; the two first quills shorter than the third, which is the longest. America.

Example, *Aramus scolopacius*. (*Classification of Birds.*)

The Prince of Canino places the *Tantalidæ* between the *Psophidæ* and *Scolopacidæ*, and arranges under the former the genera *Tantalus* and *Ibis*. (*Birds of Europe and North America.*)

Mr. G. R. Gray makes the *Tantalinæ* the fifth and last subfamily of the *Ardeidæ*, placing it next to the *Ciconiinæ*, and arranging under it the following genera:—

Tantalus, Linn. *Ibis*, Mœhr. *Geronticus*, Wagl. *Cercibis*, Wagl. *Theristicus*, Wagl. *Phimosus*, Wagl. *Harpiprion*, Wagl. *Falcinellus*, (Ray) Bechst. *Aramus*, Vieill.

Mr. Gray gives the synonyms of all these genera. (*List of the Genera of Birds*, 2nd edit.)

We proceed to illustrate the Ibises of America by Nuttall's description of the *Scarlet Ibis*, *Ibis rubra* of Vieillot, *Tantalus ruber* of Linnæus, *Red Curlew* of Catesby.

This species is 23 inches in length and 37 in alar extent. Bill 5 inches long, thick, and of a somewhat square form at the base, gradually bent downwards and sharply ridged; black, except near the base, where it inclines to red. Iris dark-hazel. The face naked, slightly wrinkled, pale-red. Chin bare, wrinkled also. Plumage rich, glowing scarlet, except about three inches of the extremities of the four outer quill-feathers, which are deep steel-blue. Legs pale red; the three anterior toes united by a membrane as far as the first joint. (Nuttall.)

'This brilliant and exclusively American species, inhabits chiefly,' says Nuttall, 'within the tropics, abounding in the West India and Bahama Islands, and south of the equator, at least as far as Brazil. They migrate in the course of the summer (about July and August) into Florida, Alabama, Georgia, and South Carolina; but retire into Mexico, or the Caribbean Islands, at the approach of cool weather. They generally associate in numbers, frequenting the borders of the sea, and the banks and æstuaries of neighbouring rivers, feeding on small fry, shellfish, crustacea, worms, and insects, which they collect at the ebbing of the tide. They are said to be in the habit of perching on trees in companies; but they lay their eggs, which are greenish, on the ground, amidst the tall grass of the marshes, on a slight nest of leaves. When just hatched, the young are black, soon changing to grey, but are nearly white before they are able to fly; by degrees they attain their red plumage, which is not complete until the third year. The young and old associate in distinct bands. In the countries where they abound, they are sometimes domesticated, and accompany the poultry. The Ibis shows great courage in attacking the fowls, and will even defend itself from the insidious attacks of the cat. It is generally esteemed as good food; and its rich and gaudy plumage is used by the Brazilians for various ornaments.' (*Manual of the Ornithology of the United States and of Canada.*)

TAP ROOT. [Root.]

TAPAJOS. [Brazil.]

TAPE WORM. [Entozoa.]

TAPESTRY (French, *Tapisserie*; Italian, *Tappezzeria*). This name is most commonly applied to the textile fabrics, usually composed of wool or silk, and sometimes enriched with gold and silver, woven or embroidered with figures, landscapes, or ornamental devices, and used as a lining or covering for the walls of apartments. It is derived from the French 'tapis,' which is from the Latin 'tapetum,' 'tapes,' 'tapete.' The Latin word is the same as the Greek 'tapes' or 'tapis' (*τάπης*, *τάπις*). The Latin and Greek words signified a carpet or covering for a bed or couch. The French 'tapis,' though generally applied to carpets, is also used to express other figured cloths used as coverings, such as the coverings of tables; whence, most probably, we have the common expression 'on the tapis,' as applied to subjects under discussion or consideration. Of the use of the word tapestry in this more extended sense, there is an instance in Shakspere's 'Comedy of Errors,' act iv., sc. 1, where Antipholus of Ephesus sends to Adriana, informing her that

> 'In the desk
> That's covered o'er with Turkish tapestry,
> There is a purse of ducats,' &c.

Johnson, who cites this passage, gives also one from Dryden, in which tapestry is used in the sense of carpet:

> 'The casements are with golden tissue spread,
> And horses' hoofs, for earth, on silken tapestry tread.'

In this more general sense the term is used by M. Achille Jubinal, in his recently published work, entitled 'Recherches sur l'Usage et l'Origine des Tapisseries,' in which he extends his inquiry to worked or figured cloths (tapisseries à ymaiges) used for many other purposes than the covering of walls. To this work we are indebted for much of the following information respecting the history of tapestry.

The early history of the art of producing figured fabrics by the loom may be more conveniently treated of under Weaving than in this place; and it may be sufficient here to observe, that although the loom was employed from the earliest times by the Greeks and Romans for the production of ordinary tissues, its application to the weaving of ornamented or figured fabric was chiefly Oriental. It is probable also that many of the early tapestries were embroidered by hand or worked with the needle. This kind of work, of which the Bayeux tapestry is a celebrated example, was continued long after the practice of weaving tapestry in the loom had become common. The ornamented curtains of the Jewish tabernacle, described in the twenty-sixth, thirty-fifth, and thirty-sixth chapters of Exodus, are generally considered to have been embroidered by the needle. Jubinal supposes that they were worked with a needle in thread of silk, gold, or wool, in such a manner as to imitate the brilliancy of the plumage of birds; but he conceives that the vail of the Holy of Holies, which is described in the English translation of the Bible as of 'cunning work' (*Exodus*, xxvi. 31; and xxxvi. 35), and which was ornamented with cherubim, was produced by the skill of the weaver, 'that is to say, executed by the shuttle with woofs of various colours, and in woven stuff.'

The Jews are supposed to have derived their skill in embroidery and other ornamental work of similar character from the Egyptians, who produced figured cloths both by the needle and the loom, and practised the art of introducing gold thread or wire into such work. Wilkinson observes (*Manners and Customs of the Antient Egyptians*, vol. iii., p. 128), 'Many of the Egyptian stuffs presented various patterns worked in colours by the loom, independent of those produced by the dyeing or printing process, and so richly composed that they vied with cloths embroidered by the needle.' Jubinal quotes several antient authors who refer to figured tissues as made and used by the Egyptians and other nations of antiquity. Tapestry was used by the Babylonians to represent the mysteries of religion, and to perpetuate historical facts. Philostratus, in his Life of Apollonius of Tyana, mentions Babylonian tapestry ornamented with silver and gold. The Greeks practised the art of embroidering figures upon cloth, and attributed its invention to Minerva. Homer alludes, in several passages of the 'Iliad' and 'Odyssey,' to embroidered stuffs of the character designated by Jubinal 'tapisseries à ymaiges,' among which he comprises even some articles of dress. Without attempting to pursue the investigation of this subject minutely, a general idea of the character of these ornamental tissues may be given by a reference to the article 'Peplum' in the 'Dictionary of Greek and Roman Antiquities,' edited by Dr. Smith; the author of the article 'Peplum' observes, that of all the productions of the loom, shawls were those upon which the greatest skill and labour were employed; and that the subjects represented upon them were so various and tasteful, that poets delighted to describe them. He adds that 'Euripides describes one which represented the sun, moon, and stars; and which, with various others containing hunting-

pieces and a great variety of subjects, belonged to the temple of Apollo at Delphi, and was used to form a magnificent tent for the purpose of an entertainment (*Ion*, 1141-1162); for it is to be observed that stores of shawls were not only kept by wealthy individuals (Homer, *Odyssey*, xv., 104-108), but often constituted a very important part of the treasures of a temple (Euripides, *Ion*, 329, 330), having been presented to the divinity on numerous occasions by suppliants and devotees. (Homer, *Iliad*, vi., 271-304; Virgil, *Æneid*, i., 480, *Ciris*, 21-35.)'

Several substances appear to have been used by the antients as materials for the ornamental fabrics alluded to. Jubinal states that flax, wool, and byssus [Byssus, vol. vi., p. 81] entered into their composition; and that the richest colours, embroidery, precious stones, and gold, were used in them. It is not very clear in what form and manner gold was applied in many cases. In the third verse of the thirty-ninth chapter of Exodus, Moses speaks of beating gold into thin plates, and then cutting it into wires, to work it into the ephod with cunning work; and Wilkinson states that probably the gold thread used in Egyptian embroidery was formed in like manner, and rounded by the hammer. Beckmann (*History of Inventions*, vol. ii., p. 212, &c.) enters minutely into this question, and states that he had not met with a single passage in antient authors where mention is made of metal being wire-drawn; yet Jubinal thinks that gold was perhaps sometimes used in antient tapestry in the form of fine drawn wires, flattened and wound round threads in a manner resembling modern gold thread. He further supposes that gold was sometimes introduced subsequently to the weaving of the tissue, by loosening its texture, and inserting the gold between the threads.

Scanty as are the notices of tapestry in antient writers, our information respecting it during the middle ages is not much fuller. Jubinal observes that we find females engaged in working tapestry with the needle from the earliest epochs of the French monarchy. Gregory of Tours, writing towards the close of the sixth century, in his description of the rejoicings which followed the profession of Christianity by Clovis and his people, speaks of the streets being shaded with painted cloths or curtains (*velis depictis*), and the churches being adorned with hangings; and again, in describing the consecration of the church of St. Denis, he mentions tapestries embroidered with gold and garnished with pearls. The fabrication of tapestry-hangings by the loom appears to have been introduced into France, at the earliest, about the ninth century, until which time the needle had been used exclusively in their production; and, long after that period, the two processes were practised concurrently. At this time we often find embroidered cloths enumerated among the decorations of churches. Jubinal quotes Father Labbe for the statement that many tapestries were made for the church of Auxerre prior to the year 840; and he relates that, about 985, there existed in the abbey of St. Florent, at Saumur, a great manufactory of stuffs, especially tapestries, which were woven by the inmates. From contemporary notices, it is evident that there was a celebrated manufacture of tapestry at Poitiers as early as 1025. Nor was the manufacture of tapestry confined to France at this period. The inhabitants of the north of Europe also practised it, and English embroidery was much admired and highly prized on the Continent. In the East also, where the art had been cultivated from the earliest antiquity, fine embroidery was produced in the eleventh century. Much of the early Oriental tapestry was adorned with grotesque figures; and, long after it became usual to depict natural figures and scenery upon tapestry, such devices were often used in ornamental borders.

In the twelfth and thirteenth centuries the use of tapestry extended greatly. It passed from churches and monasteries, in which it had been used for curtains, palls, altar-cloths, vestments, &c., to the residences of the nobility. Respecting this change, Jubinal observes:—'If, in the solitude of the cloister, the monks had, as we have seen, practised the weaving of wool and silk for the sake of occupation, ladies and their followers, shut up in their castles during the long evenings of winter, the tedium of which was interrupted only by the perusal of works of piety or chivalry, embroidered with their needles the glorious actions of our forefathers. The high walls of these cold rooms, built of stone, spoke far more effectually to the hearts and imaginations of those who lived under their protecting shelter, when they were covered with interesting histories, with important instruction, or with glorious remembrances of the past, than when nothing appeared to veil their nakedness.' The use of tapestry in this way was one of the luxuries introduced from the East in consequence of the increased intercourse occasioned by the crusades. The crusaders brought accounts of the Oriental practice of covering walls with prepared and ornamented skins, chiefly those of goats and sheep. These, which were probably at first used of their natural size and shape, were, at a later period, cut into rectangular pieces, about two feet high, and rather less in width, and united by sewing into very solid and handsome hangings, which were well adapted to resist damp. Such hangings, or leather tapestry, were manufactured much at Venice and Cordova, and were sometimes either gilt all over, or ornamented with gilt devices, in which case they bore the name of *d'or basané*. The Oriental origin of the more ordinary kind of tapestry is indicated by the name *Sarazins* or *Sarazinois*, which was frequently applied in France to the early manufacturers.

Numerous allusions to the use of tapestry in the fourteenth and fifteenth centuries, collected from contemporary documents, are given by Jubinal. It was then not only used to cover the nakedness of interior walls, but was also employed, on great occasions, as for instance on the public entries of princes, to decorate streets, and to impart a joyful appearance to towns and public places. It formed part of the decorations of festal halls, and was employed to ornament the galleries and other erections required at tournaments. Rich embroidery was also much employed in the decorations of the horses and men who formed the actors in those chivalric amusements; and the brilliant, though often grotesque devices of heraldry, which formed so important a part of the display upon such occasions, afforded extensive employment to the workers of tapestry and other ornamented tissues.

The art of making tapestry, for which the Flemings had been celebrated from the twelfth century, made considerable progress in Flanders in the fourteenth century, and attained its highest perfection there in the fifteenth. Guicciardini has ascribed the invention of tapestry to Flanders; but, if received at all, this statement must be supposed to refer merely to such as is produced by the loom. It is certain however that Europe is much indebted to the Flemings for the revival and improvement of tapestry, and for the production of many of the finest specimens yet existing. The countess of Wilton, whose interesting volume on 'The Art of Needlework' contains much information upon the subject of tapestry, is probably correct in assuming that the *weaving* of tapestry-hangings was not practised until they had become, from custom, a thing of necessity. 'Unintermitting and arduous,' she observes, 'had been the stitchery practised in the creation of these coveted luxuries, long, very long, before the loom was taught to give relief to the busy finger.' Tapestry manufactories were early established at Brussels, Antwerp, Oudenarde, Lisle, Tournay, Bruges, and Valenciennes; but that of Arras* was more celebrated than any other, and its productions were so highly prized, that the name *arras* became a common expression for the finest tapestry generally, whether made in that place or elsewhere. The hangings of Arras, as well as those of other manufactories in France, were, says Jubinal, for the most part executed in wool. Hemp and cotton were also used in them, but no silk or gold thread. The fabrication of tapestries formed of these substances was carried on chiefly at Florence and at Venice. The recollection of this difference is important in discovering where old tapestries were made, and Jubinal refers to instances of the difference in some of those engraved in his great work on this description of monuments. Writing of the period under consideration, he observes that the devices (*ymaiges*) of the tapestry were very various. We have seen that they sometimes represented scenes from antient history, from the fabulous stories of heroes, and from modern historical events; but the imagination of the tapestry-designers did not stop

* Tapestry of Arras, representing the battles of Alexander the Great, formed part of the present sent by the king of France, in 1396, to the sultan Bajazet, to induce him to ransom some captives taken at the battle of Nicopolis. (Macpherson, *Annals of Commerce*, vol. i., p. 608.)

there. The hangings of the fourteenth century often represented hunts, fantastical animals, or the occupations peculiar to the different seasons of the year; and romantic and chivalric poems afforded a rich store of subjects for illustration. Jubinal quotes inventories of tapestries, receipts, &c., of the fourteenth century, in which tapestries of the above and of several other varieties are mentioned. The account given of those belonging to Charles V. of France is particularly curious. It is taken from an inventory preserved in the Bibliothèque du Roi, which, besides tapestries ornamented with figures, mentions heraldic tapestries (*tapisseries d'armoirie*), and *tappiz velus*, or hairy or shaggy tapestry. The fifteenth century affords many similar documents, though Jubinal does not give them so fully. He gives however very long extracts from a MS. in the Bibliothèque du Roi respecting some old tapestries, from which it is evident that the names *tapis Sarrazinois* and *tapis de Turquie** were often applied to hangings fabricated in the West, they being probably made in imitation of Oriental work. In this epoch tapestry was often alluded to by poets, and to it is attributed the fabrication of most of the tapestries to which the term 'tapisseries historiées' has been applied.

The sixteenth century, which was an age of general improvement in France, gave a new impulse to the production of tapestry. Francis I. founded the manufactures of Fontainebleau, in which threads of gold and silver were skilfully introduced into the work. It was, we are informed, with this new impulse that the practice was commenced of weaving tapestry in a single piece, instead of composing it, as before, of several smaller pieces joined together. This prince brought Primaticcio from Italy [Primaticcio, Francesco, vol. xix., p. 1], and, among other works of art, commissioned him to make designs for several tapestries, which were woven at Fontainebleau. Francis spared no pains in the encouragement of this department of the fine arts. He engaged Flemish workmen, whom he supplied with silk, wool, and other materials, and paid liberally for their labour; and documents exist to prove that he also patronized the tapestry-makers of Paris. Henry II., the son and successor of Francis, continued to encourage the manufactory at Fontainebleau, and established a manufacture of tapestry on the premises of the Hôpital de la Trinité, which attained its highest celebrity in the reign of Henry IV., and produced many fine tapestries. In 1594 Du Bourg, the most eminent artist connected with this establishment, made there the celebrated tapestries of St. Meri, which were in existence until a recent period; and these pleased Henry IV. so much, that he determined to re-establish the manufacture of tapestry at Paris, where it had been interrupted by the disorders of the preceding reigns. This he did in 1597, bringing Italian workers in gold and silk to assist in the work.

The narrative of M. Jubinal, from which most of the preceding facts are taken, does not extend later than the close of the sixteenth century; but, to continue the history of the tapestry manufacture in France without interruption, we may turn to the volume recently published by the Countess of Wilton. A few years after the events last mentioned, as appears from his 'Memoirs,' the Due de Sully, Henry's minister, was actively engaged in promoting this branch of industry. In 1605 were laid the foundations of new edifices for the tapestry-weavers, in the horse-market at Paris; and at that time, or a little later, Flemish workmen were engaged to superintend the manufacture. The establishment languished, if it did not become quite extinct, after the death of Henry IV.; but when the royal palaces, especially the Louvre and the Tuileries, were receiving their rich decorations, in the reign of Louis XIV., his minister Colbert revived it, and from that time the celebrated royal tapestry-manufactory of the Gobelins dates its origin. This was established in premises which had been erected by celebrated dyers named Gobelin [Gobelin, vol. xi., p. 286], but which were purchased by Louis XIV. in or about the year 1666, and adapted to the tapestry-manufacture, under the name of Hôtel Royal des Gobelins. Foreign artists and workmen were engaged, laws were drawn up for the protection and government of the manufactory, and everything was done to render it, what it has ever since remained, the finest establishment of the kind in the world. 'The quantity of the finest and noblest works that have been produced by it,' observes the work above referred to, 'and the number of the best workmen bred up therein, are incredible; and the present flourishing condition of the arts and manufactures of France is, in great measure, owing thereto.' The production of tapestry at the Gobelins is said to have attained the highest perfection in the time of the minister Colbert and his successor M. de Louvois. Le Brun, when chief director of the establishment, made many designs for working after; and M. de Louvois caused tapestry to be made from some of the finest designs of Raphael, Julio Romano, and other Italian painters. A further account of this celebrated manufacture is given in the elegant volume which has just appeared under the title of 'The Hand-book of Needlework,' the authoress of which writes under her maiden name, Miss Lambert. She states that the manufacture declined greatly at the Revolution, but was revived under the government of Napoleon, and has ever since been carried on successfully, though by no means to the same extent as formerly. About 1802 ninety persons were employed in it, chiefly in preparing tapestry for the palace of St. Cloud. 'The pieces executed,' according to the work last named, 'are generally historical subjects, and it occasionally requires the labour of from two to six years to finish a single piece of tapestry.' 'The productions of this manufactory,' says the same authority, 'which is entirely supported by the government, are chiefly destined for the royal palaces, or for presents made by the king; but some few pieces, not designed as such, are allowed to be sold.' Wool is the only material now used, it being found to retain its colours better than any other; and in connection with the weaving establishment is one for dyeing wools, under the direction of able chemists, in which many colours are dyed for this purpose exclusively. From a passage in Evelyn's 'Diary' (Oct. 4, 1683), in which he speaks with admiration of some new French tapestry he had seen in the apartments of the duchess of Portsmouth, it appears that the productions of this manufactory were known in England at that time.

The preceding historical notices respecting tapestry refer almost exclusively to France, but we must retrace our steps to take a brief review of the use and manufacture of this kind of fabric in England. Respecting the Anglo-Saxon period, it is observed in the 'Pictorial History of England' (vol i., p. 323):—'The dwellings of the higher classes appear to have been completely and sometimes splendidly furnished: their walls were hung with silk richly embroidered with gold or colours. The needle-work for which the English ladies were so famous was herein displayed to great advantage. Ingulphus mentions some hangings ornamented with golden birds in needle-work, and a veil or curtain on which was represented in embroidery the destruction of Troy. In the Anglo-Saxon poem of Beowulf we read that, in 'the great wine-chamber'—

> 'There shone variegated with gold
> The web on the walls.
> Many wonders in the sight
> Of each of the warriors
> That would gaze on it became visible.'

'The Saxon term for a curtain or hanging was *wanrift*; and, in the will of Wynflœda, we find the bequest of a long *heall wahrift* and a short one. The same lady also bequeaths three coverings for benches or settles (*setlhreegl*).' The Bayeux Tapestry (vol. iv., p. 68) is perhaps the most antient piece of needlework in existence. It was probably owing to the expense of such hangings, when of large size, and the very long time required for their production, that the less comfortable device of painting the walls of chambers was extensively adopted in the early Norman period. Of this time the work before quoted observes (vol. i., p. 635):—'The hangings of needle-work and embroidery which adorned the walls of the Anglo-Saxon palaces, seem to have been partially superseded in the course of this period by the fashion of

* In describing, in a subsequent page, a remarkable Persian tapestry of the sixteenth century, embellished with emblematical devices, which is now in the possession of the Marquise de Lagoy, at Aix, Jubinal observes that the finest Persian tapestries are the produce of Khorassan, especially of the town of Yezd. These, he adds, are what we commonly call Turkish tapestries, not because they come from the Ottoman empire, but because, before the discovery of the passage round the Cape of Good Hope, Turkey formed the only way of communication with Persia. The establishment of the royal tapestry-manufactories in France put an end to the importation of foreign tapestry; but the art of working it is stated to be continued successfully in the East, even to our own day.

painting on the walls themselves, or the wainscot of the chamber, the same historical or fabulous subjects which had hitherto been displayed in threads of colours and gold.' Many instances might be enumerated of this kind of decoration, but it is sufficient to refer to the directions given by Henry III. early in his reign, for the painting of his wainscoted chamber in Winchester castle with the same pictures with which it had been previously adorned; a circumstance presumed by Walpole to indicate the very early existence of historical painting in England. The practice alluded to appears to have extended considerably during the reigns of Henry III. and his immediate successors; and, according to the same authority (vol. i., p. 864), the paintings were, in several instances, directed to be made in imitation of needle-work tapestries. Lady Wilton states that tapestry of needle-work, like the Bayeux tapestry of Matilda, which 'had been used solely for the decoration of altars, or the embellishment of other portions of sacred edifices, on occasions of festival or the performance of solemn rites, had been of much more general application amongst the luxurious inhabitants of the South, and was introduced into England as furniture hanging by Eleanor of Castile.' That tapestry was not originally introduced by that queen will be seen by the facts stated above; and we know not whether there is any further authority for the statement than the mention, by Matthew Paris, of her having used tapestry for covering floors, the word being apparently used in the sense of carpet. (*Pict. Hist. of England*, vol. i., p. 865, note.) Chaucer mentions a 'tapiser,' in company with a 'webbe' and a 'dyer,' among his Canterbury pilgrims; from which circumstance it may be presumed that the business was not a very uncommon one towards the close of the fourteenth century. In the fifteenth century the use of tapestry greatly extended in England; but then, and for long after, the principal supply appears to have been from the Continent. In the sixteenth century a kind of hanging was introduced which holds a place intermediate between painted walls and woven or embroidered tapestry. Shakspere alludes to these hangings under the name of 'painted cloths.'*

The appearance of the rich tapestry common in the Elizabethan period is admirably described by Spenser, in his 'Faerie Queene,' book iii., canto ix., in the account of the tapestry seen by Britomart in the apartments of the house of Busirane, in the following lines:—

> 'For round about the walls yclothed were
> With goodly arras of great majesty,
> Woven with gold and silke so close and nere,
> That the rich metall lurked privily,
> As faining to be hid from envious eye;
> Yet here, and there, and everywhere, unwares
> It shewd itselfe, and shone unwillingly;
> Like a discoloured snake, whose hidden snares
> Through the greene gras his long bright-burnisht back declares.

The poet described what he was in the habit of seeing, and sufficient remains yet exist to attest the accuracy of his description; although in most cases the brilliancy of the metallic threads and the beauty of the colours are greatly impaired, and in some instances the gold and silver threads have been artfully withdrawn, their intrinsic value proving too strong a temptation for cupidity to resist.

The introduction of tapestry-weaving into England is usually attributed to a gentleman named Sheldon, late in the reign of Henry VIII. Lady Wilton mentions indeed an intimation by Walpole of its origin as early as the time of Edward III.; but if any attempt was made to introduce the art at that time, it does not appear to have produced any important result. According to her 'Art of Needlework,' Sheldon allowed an artist, named Robert Hicks, to use his manor-house at Burcheston, in Warwickshire, for the practice of the art; and mentioned him in his will, which was dated 1570, as 'the only auter and beginner of tapistry and arras within this realme.' At Burcheston were worked in tapestry, on a large scale, maps of Oxfordshire, Worcestershire, Warwickshire, and Gloucestershire, some fragments of which were, it is stated, in Walpole's collection at Strawberry Hill. Little more is known of this establishment. James I. endeavoured to revive the manufacture of tapestry by encouraging and assisting in the formation of an establishment at Mortlake, about 1619, under the management of Sir Francis Crane. James I. gave 2000*l.* towards the formation of this establishment, which appears to have been originally supplied with designs from abroad, but subsequently by an artist named Francis Cleyne, or Klein, a native of Rostock, in the duchy of Mecklenburg, who was engaged for the purpose. This undertaking was a favorite hobby both with James and his successor, who regarded Cleyne so favourably that he bestowed upon him, in 1625, an annuity of 100*l.* (Rymer's *Fœdera*, vol. xviii., p. 112), which he enjoyed until the civil war. In the same year Charles I. granted 2000*l.* a year for ten years to Sir Francis Crane, in lieu of an annual payment of 1000*l.* which he had previously covenanted to pay for that term, as the grant recites, 'towards the furtherance, upholding, and maintenance of the worke of tapestries, latelie brought into this our kingdome by the said Sir Francis Crane, and now by him and his workmen practised and put in use at Mortlake, in our countie of Surrey;' and of a further sum of 6000*l.* due to the establishment for three suits of gold tapestries. (*Fœdera*, vol. xviii., p. 60.) After the death of Sir Francis Crane, his brother, Sir Richard, sold the premises to the king, and during the civil war they were seized as royal property. After the Restoration, Charles II. endeavoured to revive the manufacture, and employed Verrio to make designs for it, but the attempt was unsuccessful. Lady Wilton however conceives that, although languishing, the work was not altogether extinct, 'for,' she observes, 'in Mr. Evelyn's very scarce tract entitled "Mundus Muliebris," printed in 1690, some of this manufacture is amongst the articles to be furnished by a gallant to his mistress.' During its period of prosperity, this manufacture produced the most superb hangings, after the designs of celebrated painters, with which the palaces of Windsor Castle, Hampton Court, Whitehall, St. James's, Nonsuch, Greenwich, &c., and many of the mansions of the nobility, were adorned. Five, at least, of the cartoons of Raphael, which appear to have been bought by Charles I. for that purpose, were worked in tapestry at Mortlake. These celebrated works were designed for the purpose of being copied in tapestry, and were originally worked in Flanders. [CARTOON, vol. vi., p. 330.] An act of parliament was passed in 1663 to encourage the linen and tapestry manufactures of England, and to restrain the great importation of foreign linen and tapestry.

The use of the word 'hangings,' as applied to tapestry, as well as to other kinds of lining for rooms, perhaps sufficiently indicates the manner in which such decorations were formerly put up. 'The tapestries,' observes the Countess of Wilton, 'whether wrought or woven, did not remain on the walls as do the hangings of modern days: it was the primitive office of grooms of the chamber to hang up the tapestry, which, in a royal progress, was sent forward with the purveyor and grooms of the chamber.' She relates a curious anecdote in illustration of this practice. Henry IV. of France, wishing to do honour to the pope's legate, the cardinal of Florence, when visiting St. Germain-en-Laye, sent orders to hang up the finest tapestry; but, by an awkward blunder, the suit selected for the cardinal's chamber was embellished with satirical emblems of the pope and the Roman court. The mistake was discovered by the Duc de Sully, on whose authority the anecdote is given, and another suit was substituted for that with the offensive devices. In a subsequent chapter, on 'The days of good Queen Bess,' after showing the universality of tapestry and similar decorations in the houses of the nobility and gentry of England, it is stated that tapestry was at that time suspended upon frames, which were probably, in many cases, at a considerable distance from the walls, as we frequently read of persons concealing themselves, like Falstaff (*Merry Wives of Windsor*, act iii., scene 3), 'behind the arras.'

The interest attached to antient tapestries as historical monuments, as well as in the character of works of art, is of no mean order. The most important work on this department of archæology is that of M. Jubinal, the author of the historical treatise quoted in the former part of this article, entitled 'Les Anciennes Tapisseries Historiées,' in which are given minute descriptions, illustrated by many large folio plates, of the most remarkable tapestries made from the eleventh to the sixteenth century, and preserved to the present time. Such monuments, as he observes in his preface, sometimes represent to us, with a charming and

* In Malone's edition (1821) many references to this kind of substitute for woven or embroidered tapestry, by various authors, are given. See notes on 'As you like it,' act iii., s. 2 (vol. vi., pp. 434-6), and 'Henry IV.,' Part 2, act ii., s. 1 (vol. xviii., p. 51). From the latter passage it would appear that the hangings alluded to were sometimes painted in water-colours.

faithful *naïveté*, grave historical events, and sometimes scenes of gaiety. 'There they show us a siege or a tournament; here, a feast; a little farther, a chace; and always, whether chace, banquet, tournament, or siege, all is, as Montaigne would have said, pourtrayed to the life; they all retrace to us most literally the mode of life of our fathers, showing us their residences, their churches, their dresses, their arms, and even (thanks to their explanatory legends) their language at different epochs. Further than this, if we refer to the inventory of Charles V., made in 1379, we find that all the French literature of the fruitful ages preceding the era of that wise monarch had been by his orders translated into wool.' At a later period, although the beauty of tapestry was increased by improvements in the arts of weaving and dyeing, and by the adoption of superior designs, much of its peculiarly interesting character was lost. Jubinal, in the smaller work frequently quoted in the earlier part of this article, regrets the disappearance of the Gothic labels, which contained quaint descriptions of the subjects represented; of the peculiar architecture of the middle ages (*architecture à ogives*), and of the furniture and dresses of our forefathers; and he conceives that their place is but ill supplied by the imitation, 'clever in the great masters, but detestable in their disciples,' of Greek and Roman forms, of which he refers to 'celebrated and grievous examples in the compositions of Rubens reproduced by the manufactory of the Gobelins; in the tapestries of Beauvais, and in those of Aubusson.'

In the primitive method of working tapestry with the needle, the wool was usually applied to a kind of canvas, and the effect produced was coarse and very defective; but some finer kinds of tapestry were embroidered upon a silken fabric. The process of weaving by the loom, after the manner known as the *haute lisse*, or high warp, was practised in the tapestries of Flanders (and, according to Jubinal, in those of England also), as early as the fourteenth and fifteenth centuries; the only essential difference between these and the productions of modern times being that previously noticed, the comparative size of the pieces woven in the loom. The weaving of tapestry, both by the 'haute lisse' and the 'basse lisse,' appears to be of Oriental invention; and the difference between the two methods may be briefly described. In the 'haute lisse' the loom, or rather, the frame with the warp-threads, is placed in a perpendicular position, and the weaver works standing; while in the 'basse lisse' the frame with the warp is laid horizontally, and the weaver works in a sitting position. In weaving with the 'basse lisse,' which, Miss Lambert observes, is now relinquished, the painting to be copied is laid beneath the threads of the warp, which are stretched in a manner resembling that of common weaving, the pattern being supported by a number of transverse threads stretched beneath it. The weaver, sitting before the loom, and leaning over the beam, carefully separates the threads of the warp with his fingers, so that he may see his pattern between them. He then takes in his other hand a kind of shuttle, called a *flûte*, charged with silk or wool of the colour required, and passes it between the threads, after separating them in the usual way by means of treddles worked by the feet. [Weaving.] The thread of woof or shoot thus inserted is finally driven close up to the finished portion of the work by means of a reed or comb formed of box-wood or ivory, the teeth of which are inserted between the threads of the warp. In this process the face of the tapestry is downwards, so that the weaver cannot examine his work until the piece is completed and removed from the loom. The frame of the 'haute lisse' loom consists of two upright side-pieces, with large rollers placed horizontally between them. The threads of the warp, which usually consist of twisted wool, are wound round the upper roller, and the finished web is coiled round the lower one. The cartoon, or design to be copied, is placed perpendicularly behind the back or wrong side of the warp, and then the principal outlines of the pattern are drawn upon the front of the warp, the threads of which are sufficiently open to allow the artist to see the design between them. The cartoon is then removed so far back from the warp that the weaver may place himself between them with his back towards the former, so that he must turn round whenever he wishes to look at it. Attached to the upright side-pieces of the frame are contrivances for separating the threads of the warp, so as to allow the *flûte*, or broach, which carries the woof, to pass between them. Like the weaver with the 'basse lisse,' the operator works, as it were, blindfold; but by walking round to the front of the loom he may see the progress of his work, and may adjust any threads, which have not been forced into their right position by the reed or comb, with a large needle, called an *aiguille à presser*. The process of working with the 'haute lisse' is much slower than the other, and is indeed, says Jubinal, almost as slow as that of working with the needle. Lady Wilton, in describing the productions of the Hôtel Royal des Gobelins, observes that 'Not the least interesting part of the process was that performed by the *rentrayeurs*, or fine-drawers, who so unite the breadths of the tapestry into one picture, that no seam is discernible, but the whole appears like one design.' Now, however, the pieces are woven so wide that joining is very seldom resorted to, even for the largest pieces.

(Jubinal, *Recherches sur l'Usage et l'Origine des Tapisseries à Personnages, dites Historiées; The Art of Needlework*, edited by the Right Honourable the Countess of Wilton; *The Handbook of Needlework*, by Miss Lambert; &c.)

TAPHOZO'US. [Cheiroptera, vol. vii., p. 24.]

TAPIO'CA, a farinaceous substance, prepared in South America from two species of Janipha, or the bitter and sweet Cassada or Manioc plants, which two were long regarded as one species, and comprehended under the name of Jatropha Manihot, till Pohl distinguished them, calling the bitter *Manihot utilissima*, and the sweet *Manihot Aipi* (Pohl, *Pl. Brasil.*, ic. i. 32 t. 21). The chief distinction between them is that a 'tough ligneous fibre or cord runs through the heart of the sweet Cassava root, of which the latter is destitute.' Though the bitter contains a highly acrid and poisonous juice, from which the sweet is exempt, yet the bitter is cultivated almost to the entire exclusion of the other, which is probably owing to the greater facility with which it can be ground or rasped into flour, owing to the absence of the ligneous centre. The poisonous principle of the bitter manioc is thought to be of the nature of hydrocyanic acid. (Guibourt, *Hist. des Drogues*, tom. ii., p. 455, 3ième ed.) It is easily dissipated or decomposed by heat or fermentation; hence the flour becomes perfectly wholesome in the process of baking the cassava bread. [Cassava, vol. vi., p. 344.] The juice, after expression, may be inspissated by long boiling, or formed into a soup, with flesh and spices, called cassarepo. By means of molasses it can be fermented and converted into intoxicating drink.

The fecula, or flour, after the juice has been carefully expressed, having been washed, and dried in the air without heat, is termed *mouchaco* in Brazil, *moussache* in the Antilles, and *cypipa* in Cayenne. This constituted the Brazilian arrow-root of English commerce. When this fecula is prepared by drying on hot plates, it becomes granular, and is called *tapioca*. It occurs in irregular lumps or grains, and is partially soluble in cold water. The granules, diffused through water, and examined by the microscope, are of great uniformity of size, and smaller than those of arrow-root from the Marantas. Tapioca is very nutritious and easy of digestion, being free from all stimulating qualities. It is therefore very necessary to distinguish it from an artificial tapioca made with gum and potato starch, which is in larger granules, whiter, more easily broken, and more soluble in cold water than the genuine.

TAPIR, *Tapirus*, the name of a genus of pachydermatous quadrupeds.

Linnæus does not notice the Tapir in the 12th (his last) edition of the *Systema Naturæ*: but Gmelin quotes it as the Hippopotamus (terrestris) pedibus posticis trisulcis. (*Syst. Nat.* x. i., p. 74. n. 2.)

Gmelin introduces it under the title *Tapir*, between Hippopotamus and Sus.

Cuvier arranges the genus as the last of his *Pachydermes Ordinaires*, making it immediately succeed the extinct *Palæotheria* and Lophiodons. The genus was well known to the older zoologists who wrote on the natural products of America, as we shall hereafter see.

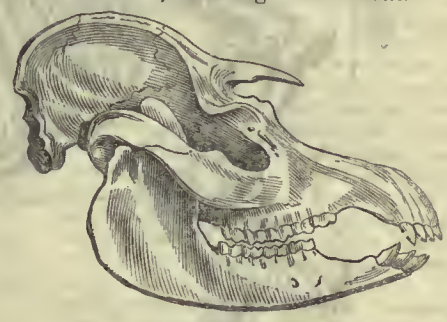
Organization.

Skeleton. When viewed in profile, the pyramidal elevation of the *skull* of the Tapir, calling to mind what is to

be seen in the hog, strikes the observer forcibly. But the pyramid of the Tapir differs from that of the hog in having only three faces; and also in this, that its anterior line is formed by the meeting of the lateral faces, and it is only towards the front that it is dilated into a triangle, which is due to the frontal bones: these are early united and directed a little backwards. At the middle of the base of this triangle, to which the bones of the nose are articulated, is a point which penetrates between them; and from the two sides above the orbits descends a deep furrow produced by the structure of the upper border of the orbit, and which approaches towards the suborbital hole: it serves for the insertion of the muscles of the proboscis. The orbit descends lower than the mid-height of the head, is very wide, and has the postorbital apophyses but little marked.

That part of the cranium which is in the temporal fossa is convex. The occiput is a small demi-oval extremely concave plate, because the occipital crest projects considerably backwards in a parabolic shape. The occipital bone ascends on the cranium. The frontal bones descend largely in the temple, and are there articulated with the lachrymal, the palatine, the two sphenoids, and the temporal bone. The parietals are square, very large, occupying a great portion of the sagittal crest, and united also early between them. The nasal bones are no less striking than the form of the cranium. They are very short, articulated to the frontals by their base, and to those of the jaws by a descending apophysis; but they are free and projecting, forming a kind of triangular penthouse above the cavity of the nostrils. This structure, which reminds the observer of that of the elephant, indicates the presence of a moveable proboscis. The aperture of the osseous nostrils thus becomes extremely long, nearly horizontal, and bordered in great part by the maxillary bones, which advance well beyond the bones of the nose, to form the projecting part of the muzzle; they carry the intermaxillary bones which (a remarkable thing, observes Cuvier) were anchylosed together in the individual examined by him, although it was very young, and consequently formed but a single bone, and Cuvier remarked the same conformation in other crania. It was only in a nascent tapir, when no tooth had come forth, that he found the suture which separates the maxillaries from each other. These same intermaxillaries form a ceiling under the orbit. The lower border of the orbit and the half of the arch are due to the *os malæ*, or jugal bone; the rest to the temporal bone. The zygomatic arch is curved downwards at its anterior portion, and upwards at its posterior portion: it projects moderately outwards. The os unguis, or lachrymal bone, touches the malar bone, and advances a little on the cheek, and moderately in the orbit. There are two lachrymal bones in the very border of the orbit, separated by an apophysis, the upper of which is the largest. The suborbital hole is oval, rather large, and at a little distance in front of the suture, which unites the jugal and the lachrymal to the maxillary bone. The incisive hole is elliptical and very long, in great part, in the maxillary. The posterior nasal fossæ notch the palate towards the fifth molar. The suture which separates the palatine from the maxillary bone corresponds with the third. The palatine bones contribute much to the pterygoid *alæ*, and the sphenoid very little: these *alæ* are short and truncate, with a small hook which represents the internal pterygoid wing, and which remains for a considerable time a detached bone. The sphenoid bone does not reach the parietal in the temporal fossa, but remains separated from it by the squamose portion. The palatine bone there forms a long and narrow tract, which proceeds forward for the length of the upper border of the maxillary bone up to the suborbital canal. Behind the glenoid cavity of the temporal bone, which is very large, is a semicircular lamina, descending vertically and directing itself forwards and inwards: it interrupts the lateral and posterior motion of the lower jaw. Between this lamina and the mastoid apophysis is a rather narrow notch where the meatus auditorius internus is found. The mastoid apophysis descends as low as this lamina. It reaches the temporal bone by its anterior tubercle, and the occipital by its point. The hole analogous to the spheno-palatine is in the middle of the orbital tract of the palatine bone. The analogue of the pterygo-palatine bone is below it, on the suture of the palatine with the maxillary bone. The optic foramen is small, and placed on the suture of the frontal and of the anterior sphenoid bones. The spheno-orbital and round foramina are only separated from each other by a delicate lamina. There is a rather large vidian canal. The oval hole is confounded with the anterior and posterior apertures, so that a great portion of the petrous bone is separated from the sphenoid and basilary by a space. The tympanic bone does not appear to be ever anchylosed with the neighbouring bones, and falls easily, as in the hedgehog, the opossum, &c.

The lower jaw exhibits a striking width at its ascending ramus, and presents a rounded contour backwards at its posterior angle. Its coronoid apophysis elevates itself in the form of a pointed falx above the condyle, which is transverse and large. The two jaws are a little concave laterally at the vacant interval of the teeth, and are very much narrowed there; their edge is trenchant.



Skull of American Tapir.

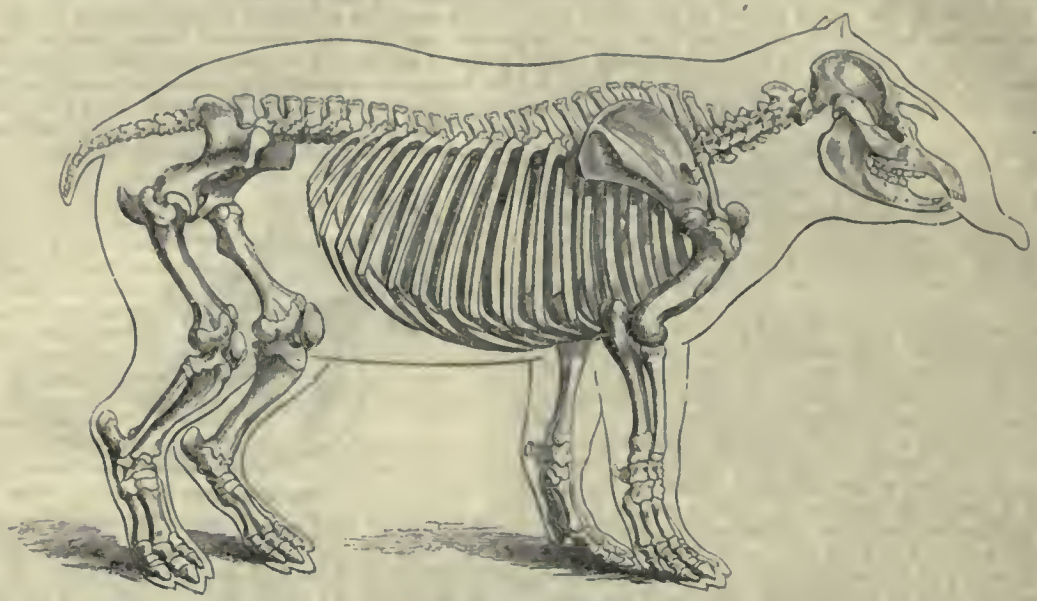
Bones of the Neck and Trunk.—The lateral apophyses of the atlas are wide, but little extended outwards: the spinous process of the axis is an elevated crest; the transverse processes are small and irregular; the odontoid is large and obtuse; the transverse processes of the three succeeding vertebræ descend obliquely, are a little widened at the end and cut nearly square; their spinous processes are very small. The fifth cervical vertebra has a small apophysis on its transverse process, which, for the rest, resembles that of the preceding vertebræ, but is rather longer: its spinous process is also rather longer; still more is that of the seventh vertebra, the transverse process of which is very small—in short, a simple tubercle. The articular facets of the cervical vertebræ rise obliquely from within outwards, so that the articular facet of one vertebra is below that which responds to the preceding vertebra. The bodies of the vertebræ are convex forward and concave behind, an organization which is more or less repeated in the rest of the spine. The number of dorsal vertebræ amounts to twenty; the spinous apophysis of the second is the longest. They decrease and incline backwards to the eleventh, from which they become straight, square, and nearly equal. Their articular apophyses are so fitted that those of one vertebra are in advance and above those which correspond with it in the vertebra below. Cuvier found twenty pairs of ribs in one individual, nineteen in another, eight of which are true, all slender and rounded for the greatest part of their length. The breast-bone is composed of five bones: its anterior portion is compressed, and projects in the form of a ploughshare. There are four lumbar vertebræ, the transverse apophyses of which are rather large. Those of the last, which are rather shorter and oblique, are articulated with the first sacral vertebra. These transverse apophyses have on their base the same elevated crests as the dorsals have for articulation with the ribs.

The *os sacrum* of the adult consists of seven vertebræ, the spinous apophyses of which are distinct and inclined backwards; the five last of these apophyses are short and terminate by a widened disk. The tail has seven vertebræ.

Bones of the Extremities.—The blade-bone has a strong semicircular notch towards the lower part of its anterior border; the rest of this border is round as well as the upper border: the posterior border makes an angle upwards and then descends a little concave. There is neither acromion nor coracoid process, if a hook-like process be excepted. The spine of the bone terminates at the lower third of it; its greatest projection is at its middle; the articular surface is oval and higher than it is long. This

blade-bone, says Cuvier, emphatically, and not more emphatically than truly, cannot be confounded with that of any other animal.

The head of the humerus is powerful, behind the axis of the bone. Its large tuberosity is bilobated by a rounded notch; its bicipital canal is simple and not wide; the ridge is little marked; the condyles do not project much. The radial articular face is divided by a projecting rib into an entire pulley on the internal side, and the half of one on the external side; both the one and the other correspond to projections of the radius, so that this last has no rotation. It is even probable, observes Cuvier, that with age it is anchylosed to the ulna, which remains throughout its length on the external edge of the arm. The upper head of the radius is nearly rectangular; its body, rounded in front, is flattened behind. The body of the ulna is triangular. One of its crests follows the external crest of the radius.



Skeleton of American Tapir.

The carpus of the Tapir bears a near resemblance to that of the Rhinoceros, especially in having, like it, a single small bone articulated with the wedge-shaped and unciform bones, in lieu of the trapezoid and thumb; but this bone is articulated with the metatarsal bone of the index, which is not the case in the rhinoceros. The other bones of the wrist are nearly of the same form, excepting that their width is less in proportion to their height, a condition which is true even with regard to the unciform bone, although it has to carry two complete metacarpals, whilst in the rhinoceros it only carries one and the vestige of another. The pisiform bone is also longer in proportion in the Tapir. The metacarpal of the middle finger is longest and straightest; those of the index and ring-finger are curved nearly symmetrically one with reference to the other, as in the rhinoceros. But the Tapir has also one small, short, and rather irregular metacarpal. The three first fingers are those which touch the earth, and their ungual phalanges resemble those of the rhinoceros; the little finger does not touch the ground. The first phalanges are longer than they are wide, but the contrary is the case with regard to the second.

The widened part of the ossa ilii is very broad transversely, and a little concave outwards. The external edge of this bone is larger than the internal one; the anterior border is largely concave, and the two spines are, as it were, truncated; its neck is narrow, with reference to its length; the oval holes are longer than they are wide, and the posterior extremity of the ischium terminates in a point very distant from its correspondent. The anterior passage of the pelvis is as long as it is wide, and nearly circular.

The femur has its great trochanter pointed, forming a projection backwards, and giving off a rib which descends along the external border. Besides the two ordinary trochanters, there is a third, which is flattened and recurved in front: In these points its resemblance to that of the horse is perceptible, but it differs much in having the two borders of the rotular pulley nearly equal. The fibula is curved outwards, which separates it a little from the tibia: this last has its upper head rather marked, but the tuberosity which terminates this end above is obtuse and curved but little. Its lower head is wider than it is long, is oblique, and its antero-posterior diameter on the internal side is wider, and this border more projecting than that of the fibular side.

The tarsus of the Tapir is still better modelled than its carpus after that of the rhinoceros, of which it seems to be only a repetition: only the os calcis is much more elongated and more compressed; but its facets are the same. The neck of the astragalus is longer and touches the cuboid bone by a narrower facet. There is no vestige of a hind toe, but the little finger is represented by an elongated bone, bent at the end, articulated to the scaphoid, to the small cuneiform and the external metatarsal bones. The posterior tubercle of the cuboid bone is less projecting and less hooked than in the rhinoceros. (*Ossemens Fossiles.*)

Cuvier, in his osteological comparison of the Indian Tapir with the American form, observes that a glance at the profile of their respective crania is sufficient to impress upon the observer their specific differences. The forehead of the Indian Tapir is, he observes, so convex, that it rises higher than the occiput: it elevates in its rise the nasal bones, which much prolongs the ascending part of the jaws and the descending portion of the frontal bones along the external aperture of the bony nostrils, thus giving much wider room for the comparatively large proboscis, and adding length to the furrows where the muscles are inserted. This organization, he observes, explains why the Indian Tapir has a more powerful and extensible trunk than that of America. There is even, he adds, in the Indian species, on the base of the nasal bones at their junction with the frontal bones, and on each side, a deep fossa which does not exist in the other species. This elevation of the forehead is accompanied by a depression of the occipital crest, which, far from forming a pyramid, as in the American species, rather descends backwards. The aperture of the bony nostrils, so enlarged by the prolongation of the maxillary bones, terminates below and forwards by more elevated intermaxillaries, which are for the rest anchylosed together in early youth as in the American Tapir.

The interval between the canine and the first molar is less in proportion in the Indian Tapir, whose dentition is otherwise the same with that of the American species.

The zygomatic apophysis of the Indian species is a little higher backward and less forward: its mastoid apophysis is more transversally turned.

The occipital surface of the skull offers a difference corresponding to that of the profile, inasmuch as it is less high, but it is also much wider in proportion; and from this width results another difference in the upper surface of the cranium, namely, that the sagittal crest, instead of remaining throughout its length linear and narrow, widens much backwards, and even remains rather wide at the point where it is most narrowed by the approximation of the two temporal fossæ. The triangle which these two fossæ leave in front upon the frontal bones is also wider and its surface more convex. The triangle formed by the true bones of the nose is wider at its base. For the rest, the composition of the cranium, the connexion of its bones, its sutures, its foramina, entirely resemble, as well as the teeth, those of the American species.

Cuvier then remarks that the rest of the skeleton of the two species does not offer such appreciable differences. The blade-bone of the Indian species is rather the wider; but the notch towards the lower part is smaller and rounder. The anterior hook of the great tuberosity of the humerus is more projecting; the unciform bone of the carpus is narrower; the last phalanges of the middle anterior toe are wider and more rounded, and the same may be said of the middle toe of the hind feet; the great trochanter of the femur is larger; the neck of the astragalus is shorter: but all these differences, Cuvier observes, are of so little importance, that, without those of the crania, they would hardly justify the conclusion of specific distinction. (*Ossemens Fossiles.*)

Mr. Yarrell, in the 4th vol. of the *Zoological Journal*, gives an account of the post-mortem appearances in an American Tapir brought to this country by Lieut. Maw, R.N., which survived its arrival in the gardens of the Zoological Society in the Regent's Park only a few hours.

When dead, the animal, which was said to be about twelve months old, measured from the nose to the root of the tail 48 inches, and its girth was 35 inches. The incisor teeth $\frac{6}{6}$ were very much used; the edges coming into close contact when the molars are in action. The canines $\frac{1-1}{1-1}$ were small in the upper jaw, and removed a short distance from the lateral incisor, for the admission of the larger canines of the lower jaw; the molars were $\frac{4-4}{3-3}$. Of those in the lower jaw, the first had three lobes, with five points; the second and third two lobes, with four points. Of the four upper molars, the first had two outer and one inner point; the other three had each two lobes with four points: all the parallel points or tubercles were connected transversely by a slight triangular ridge; and each of these triangular ridges, with their connected tubercles, shut into similarly shaped cavities in the teeth opposed to them, throughout the whole length of their continuous surfaces. The second, third, and fourth upper molars had each a small additional but less elevated point on the external anterior angle, increasing somewhat in size from the second tooth backwards. On cutting through the bones of the palate in order to the complete removal of the brain, Mr. Yarrell found the crown of another molar tooth on each side, posterior to, and somewhat within the line of range of, the last exposed molar. This tooth had a fifth tubercle of increased magnitude.

The cartilage of the septum narium was thick and strong, and the central ridge of the skull very much elevated. The ligamentum nuchæ was composed of three strong cord-like portions, two of which, passing in a parallel direction from the elongated spinous process of the first vertebra, were inserted together upon the extreme superior posterior angle of the central ridge of the cranium, supporting the whole length of the elevated crest and mane. The third portion of this strong ligament passed between the other two, and was inserted into the more elevated portion of the elongated spinous process of the dentata.

The anterior portion of the sternum was keel-like and rounded in shape, and projected forwards. There were twenty ribs on each side and four lumbar vertebræ. The tracheal cartilages were firm: the rings however were incomplete throughout. One large and one small lobe formed the right lung; one large and two small ones the left: they were inflamed. The pericardium, which was loaded with fat, was of unusual thickness; but the heart presented nothing remarkable: the coats of the arteries were particularly thick and firm.

The œsophagus was narrow: the stomach presented a single cavity, rather small, measuring, when moderately distended with air, 8 inches only from right to left, and 15½ inches in circumference: the parietes were thickened about the pylorus, but the internal surface was not examined, the organ having been preserved entire: it contained a loose mass of tow, hair, string, and shreds of cloth.

The spleen was narrow, thin, and 12 inches long.

The liver was divided into four lobes:—two, one large and one small, on the right side; and two, large and equal, on the left; the lower of these last was divided and notched on the edge. There was no gall-bladder.

The small intestines, uniform in size throughout their length, measured 21 feet, and were inflamed.

The cæcum was capacious compared with the stomach, measuring 14 inches in the line of its long axis, and 24 inches in girth at the largest part, and had two deep and several smaller circular indentations externally, and marked with one strong longitudinal band on each surface; tapering somewhat to a point at its closed extremity, but without any appendix vermiformis. The colon, at two feet from its commencement, doubled suddenly upon itself, and formed a fold 16 inches long, the inner surfaces of which were closely connected. The large intestines measured seven feet in length.

The sexual organs (the animal was a female) presented about the uterus, its cornua, and the ovaria, a degree of vascularity which rendered it probable that the period of life was approaching when breeding would have commenced.

Mr. Yarrell refers to Sir Everard Home's paper in *Phil. Trans.* (1821), in which Sir Everard points out the differences existing in the skulls of the Sumatran and American Tapirs, and has described a part of the viscera of the former. In the Sumatran Tapir the stomach is large, the intestinal canal very long, and the cæcum small; in the American Tapir the stomach is small, the intestines of moderate length, and the cæcum large.

Mr. Yarrell adds, that, of the species described,

The length of the Sumatran Tapir is eight feet; and the whole length of its intestinal canal is 89 feet 6 inches. Proportion as 11 to 1.

The length of the American Tapir is four feet; and the whole length of its intestinal canal 28 feet. Proportion, as 7 to 1.

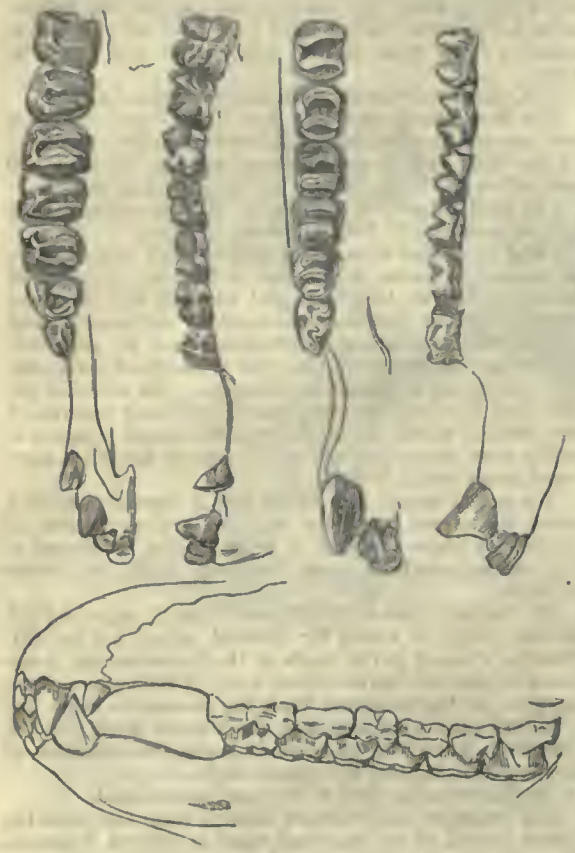
In the *Physiological Series*, preserved in the Museum of the Royal College of Surgeons in London, No. 754, is the anus of an American Tapir, in which, as in the ordinary mammalia, the intestinal canal has a distinct external orifice, situated behind, and not, as in the osseous fishes, in front of the genito-urinary outlet. Professor Owen, the author of the Catalogue, remarks that this example of the mammiferous type of anus is preserved on account of the peculiar jagged appearance and abrupt termination of the common integument at the verge of the anus.

No. 1217 of the same series is a section of the kidney of a Tapir (*Tapir Americanus*), with the arteries injected, and the pelvis laid open to show the terminations of the tubuli uriniferi, as in the horse. No. 1286 is the suprarenal gland of an American Tapir laid open, showing the central dark-coloured substance very distinctly. No. 2778 exhibits part of the vagina, with the urethro-sexual canal, vulva, and clitoris of the American Tapir, in which the clitoris projects within the anterior margin of the vulva: it is a short pyramidal body with two small lateral lobes. The urethro-sexual canal is separated from the vagina by a broad transverse semilunar fold, beneath which is the wide aperture of the urethra. No. 2527 B, is the distal extremity of the penis of the Sumatran Tapir. The upper and lateral parts of the base of the glans present three rounded processes, beyond which the extremity of the glans is continued forwards, and terminates in a large truncate slightly convex surface, in the middle of which is situated the orifice of the urethra.

Generic Character.—Molars presenting on their crown, before they are worn, two transverse and rectilineal tubercles (eollines). Nose terminated in a small movcable proboscis, but not terminated with an organ of touch like that

of the elephant; neck rather long; skin rather thick, and covered with hair, looking as if it had been close shorn; two inguinal mammæ. Anterior feet with four toes; posterior feet with three toes.

Dental formula:—incisors $\frac{6}{6}$; canines $\frac{1-1}{1-1}$; molars $\frac{7-7}{6-6}$ =42.



Teeth of Sumatran Tapir

Geographical Distribution.—Asia and America. M. Lesson observes that it was for a long time believed that this genus was peculiar to America; but that the rich and beautiful discoveries of MM. Diard and Duvaucel have proved that it is also proper to Asia: of which observation more will presently be said.

Asiatic Tapir.

Up to the year 1816 it appears to have been thought that the Tapir form was confined to America, and the species known in collections as the American Tapir seems to have been regarded as the only example of the genus. M. Lesson, who so sweepingly claims the discovery of the Asiatic species for French naturalists, is not the only zoologist of that country who puts forth such pretensions. Mr. Bennett has thus corrected those pretensions:—

'Some vague notices had reached Sir Stamford Raffles of the existence of a similar animal in Sumatra and the Malayan Peninsula; but to Major Farquhar belongs the credit of having first procured a specimen and submitted its description to the world at large. The history of this transaction affords too striking an illustration of the injustice of certain among the French zoologists to the merits of our countrymen to be passed over without observation. "The knowledge of this animal in France," says M. Desmarest, in his 'Mammalogie,' carefully shielding himself under an equivocal form of expression, "is due to M. Diard." But M. Lesson goes farther; and echoing, as usual, the dicta of his predecessor with a slight addition of his own, speaks of the Indian tapir as a species "discovered by M. Diard." Again, in the 'Dictionnaire des Sciences Naturelles,' M. Desmarest, forgetful of his former caution, heightens the farce still more by asserting that its "discovery in the forests of Sumatra and the Peninsula of Malacca is due to MM. Duvaucel and Diard." In none of these works is the least indication given that the animal in question had previously been even seen by an Englishman; much less is the fact suffered to transpire that long before M. Diard had "discovered" it, not in the forests of Sumatra or the Malayan Peninsula, but in the menagerie of the Governor-general of British India at Barrackpore, a full description, together with a figure of the animal and of its skull, had been laid before the Asiatic Society by Major Farquhar, for publication in their 'Researches.' This latter circumstance, it is true, was not mentioned by M. Frederick Cuvier when he figured the tapir of Malacca in his splendid work, from a drawing made by M. Diard in the Barrackpore menagerie, or by that gentleman himself in the published part of his accompanying letter; but there seems to have been no intention on their parts wilfully to mislead their readers. That M. Diard at least could not have been actuated by any such desire is fully proved by several passages in the note appended by him to Major Farquhar's original description, in which he speaks of the gallant officer as "the excellent naturalist who has enriched zoology with so important a discovery;" and attributes the "honour" to him "alone." Baron Cuvier too, in the recent edition of his 'Règne Animal,' silently rejects the unmerited distinction in favor of his stepson and friend; and candidly quotes, as the first describer, our, in this instance, more fortunate countryman.* After this, we trust that we shall hear no more of the "discovery" of the Indian tapir by MM. Diard and Duvaucel, who have too many real claims on the consideration of zoologists to require to be tricked out in the borrowed plumes with which it has hitherto been the fashion among our neighbours to invest them.' (*The Gardens and Menagerie of the Zoological Society delineated*, vol. i.)

Dr. Horsfield states that the first intelligence of the existence of this interesting animal in Sumatra was given to the government of Fort Marlborough at Bencoolen, in the year 1772, by Mr. Whalfeldt, who was employed in making a survey of the coast. In the month of April in that year, it is, according to Dr. Horsfield, noticed in the records, that Mr. Whalfeldt laid before the government his observations on the places southward of Cawoor, where he met with the tapir at the mouth of one of the rivers. He considered it to be the hippopotamus, and described it by that name; but the drawing which accompanied the report identifies it, says the Doctor, with the tapir. Dr. Horsfield adds that this mistake in the name may readily be explained, when it is recollected that in the tenth edition of the 'Systema Naturæ' of Linnæus the tapir is placed as a species of hippopotamus, while in the twelfth edition no mention is made of that animal.

'The learned author of the 'History of Sumatra,' William Marsden, Esq.,' continues Dr. Horsfield, 'was at that time secretary to the government at Bencoolen; and the public owes to his zeal in collecting every valuable information relating to that island the first notice of the existence of this animal, which is by the Malays in many places denominated *Kuda-ayer*, literally hippo-potamus. After the first discovery, in 1772, the tapir was not observed for a considerable period. From the same catalogue of Sir T. S. Raffles which has furnished the description, it appears that in the year 1805 a living specimen was sent to Sir George Leith, when lieutenant-governor of Penang. It was afterwards observed by Major Farquhar in the vicinity of Malacca. A drawing and description of it were communicated by him to the Asiatic Society in 1816, and a living subject was afterwards sent to the menagerie at Barrackpore from Bencoolen. At this place a drawing was made by M. Diard in the year 1818, which, accompanied by an extract from the description of Major Farquhar, was communicated to his friends in Paris, where, in March, 1819, M. Fred. Cuvier published it in his large lithographic work on the mammalia of the menagerie in Paris.'

'In the month of September, 1820, the first specimen of the Malayan tapir was received in England from Sir Thomas Stamford Raffles, with the general zoological collection of mammalia and birds, the descriptive catalogue of which, being contained in the 13th vol. of the 'Transactions of the Linnean Society,' has been already referred to. This specimen of tapir was accompanied by a complete skeleton, and the thoracic and abdominal viscera preserved in spirits of wine.' Dr. Horsfield then refers to the use made by Sir Everard Home of these materials in the paper above alluded to.

* Calling him 'Farkharie' however.

A living specimen of this species was lately brought to this country, and publicly exhibited in the garden of the Zoological Society of London, where it died more than a year ago.

Description of *Tapirus Malayanus*—*Tapirus Indicus* of the French zoologists; *Le Maïba*, F. Cuv., *Mamm.*:—'The Malay Tapir resembles in form the American, and has a similar flexible proboscis, which is six or eight inches in length. Its general appearance is heavy and massive, somewhat resembling the hog. The eyes are small; the ears roundish, and bordered with white. The skin is thick and firm, thinly covered with short hair. There is no mane on the neck, as in the American species. The tail is very short, and almost destitute of hair. The legs are short and stout; the fore-feet furnished with four toes, the hind-feet with three. In the upper jaw there are seven molars on each side, one small canine inserted exactly on the suture of the incisor bone, and in front six incisors, the two outer of which are elongated into tusks. In the under jaw there are but six molars; the canines are large; and the number of the incisors, the outer of which are the smallest, is the same as in the upper jaw. The general colour is glossy black, with the exception of the back, rump, and sides of the belly, which are white, and separated by a defined line from the parts that are black.'

Such is the description of Sir Stamford Raffles, for the accuracy of which we can vouch, having compared it with the living animal in the garden of the Zoological Society. Major Farquhar describes a young Tapir of this species which he had alive in his house thus:—'It appears that until the age of four months it is black; and beautifully marked with spots and stripes of a fawn colour above and white below. After that period it began to change colour, the spots disappeared, and at the age of six months it had become of the usual colour of the adult.' (See post, American Tapirs.)

Marsden, as we have already seen, notices the animal as the Hippopotamus; *coodo-ayer*. In Sumatra, according to Sir Stamford Raffles, it is known by different names in different parts of the country: thus by the people of Limun it is called *Saladang;* by those of the interior of Manna, *Gindol;* in the interior of Bencoolen, *Babi Alu;* and at Malacca, *Tennu*.

Habits.—The habits of this species in a state of nature are probably similar to those of the American Tapirs. In captivity, Major Farquhar describes it as of a mild and gentle disposition. 'It became as tame and familiar as a dog; fed indiscriminately on all kinds of vegetables, and was very fond of attending at table to receive bread, cakes, or the like.' Sir Stamford Raffles adds that the living specimen sent from Bencoolen to Bengal was young, and became very tractable. It was allowed to roam occasionally in the park at Barrackpore, and the man who had charge of it informed Sir Stamford that it frequently entered the ponds, and appeared to walk along the bottom under water, and not to make any attempt to swim. Sir Stamford also states that the flesh is eaten by the natives of Sumatra.

The individual exhibited in the Regent's Park was very mild and gentle.

Tapir Malayanus.

American Tapirs.

John de Laet (1633), speaking of the province of Verapaz, says that among the living quadrupeds which are there found the greatest is that which the barbarians call *Beori*, and the Spaniards *Danta*, an animal not unlike a calf, but with shorter legs and articulated after the manner of an elephant's; the anterior feet have, he states, five toes or hoofs, the posterior only four. The head he describes as oblong, the forehead rather narrow, the eyes small in proportion to the bulk, and the proboscis as being a palm long and pendulous above the mouth. When the animal is angry, he states that it erects itself, and grinning shows its teeth, which are like those of hogs. The ears he describes as acute, the neck contracted, the tail short and with few hairs, the skin very thick, so that it may with difficulty be grasped by the hand or perforated by iron. It feeds, he says, on grass and sylvan herbage. The natives, he adds, eat its flesh, and relate that they are taught venesection by this animal, for when it finds itself overloaded with blood, by rubbing against rocks it opens the veins of the legs and lets blood. There can be no doubt that the animal here meant is one of the American Tapirs.

Marcgrave gives a very rude figure, not however to be mistaken for anything but a Tapir, under the name of *Tapiereté*, *Anta* of the Spaniards, describing it and its habits with considerable general accuracy; but Mr. Bennett observes that he speaks of the teeth as consisting of ten incisors and ten molars in each jaw, an error which Mr. Bennett remarks held its ground for nearly two centuries, and having passed successively through the writings of Ray, Brisson, Buffon, Gmelin, and Blumenbach, was first corrected by Geoffroy St. Hilaire.

Towards the close of last century the fabulous clouds

that had gathered about the history of this animal began to clear away before the lights of observation. Buffon had noticed the only American Tapir then known, as the largest animal of the New World; but this can hardly be said of it when the Elk and the Wapiti are remembered. Geoffroy St. Hilaire and Baron Cuvier first accurately defined its zoological characters; and Sonnini and D'Azara gave a correct account of its habits. Buffon's figure, after a drawing by La Condamine, was the first at all approaching to accuracy. A living individual was afterwards brought to France, but died before its arrival at Paris, and furnished a still better design, published with further information, derived chiefly from Sonnini, and M. Bajon's memoir on the anatomy of the species, in the Supplement to Buffon, vol. vi.: but still some of the errors were retained; nor was the account of two other individuals living in the menagerie belonging to the Prince of Orange, by Allamand, complete.

Lieut. Maw, in his *Journal of a Passage from the Pacific to the Atlantic* (1829), speaks of the Tapir as common in the woods and rivers about Egas, there called *Anta*, and which is the same animal with the Sachywaka, Dante, or Gran Bestia of Peru, of which they had heard much both before and since embarking. Two kinds were described to them, one having the tips of its ears white, and which is the largest: when young it was stated to be striped and spotted like a deer, the spots disappearing as it grows older, till it becomes entirely of a dusky bay colour. Here we have a clear intimation of the knowledge of two species by those inhabiting the spot.

The form of the species best known has since been rendered familiar to Englishmen by the exhibition of living specimens in the gardens of the Zoological Society of London in the Regent's Park.

But this is not the only American Tapir; for M. Roulin, about thirteen years since, laid before the French Academy a description and figures of a new species inhabiting the mountainous parts of the same districts, the plains of which are frequented by the other; and his account is given in the *Annales des Sciences Naturelles:* from this it would appear that the American Tapir of the mountains is more nearly allied to the Asiatic species than the American Tapir of the plains.

We take as our example the species first known, *Tapir Americanus*, Gmel.

Description. General colour throughout deep brown approaching to black. Sides of the lower lip, band on the under and middle part of the chin, upper edges of the ears, and naked line at the junction of the hoofs pure white. Scanty hair of the body very short, closely adpressed to the surface; hardly distinguishable at a short distance. The skin beneath it is of great density, being, according to M. Roulin, not less than seven lines thick on the back, and eight or nine lines on the cheek, and so tough that Sonnini frequently shot at a female which was crossing the river with her young, without disturbing her or making her turn out of her course, though he saw the impression of a ball which he had fired on the animal's cheek. There is a thick rounded crest on the back of the neck, extending from the forehead as low as the level of the eyes to the shoulders, and bristled with a not thick mane of stiff blackish hairs. Mr. Bennett remarks that it is peculiar to the present species, but is not found, according to M. Roulin, in the female at Cayenne: although D'Azara states that the female is equally furnished with it in Paraguay. In the female brought by Lieut. Maw from Para, and formerly in the menagerie of the Zoological Society of London, it was very conspicuous. Head very long; muzzle prolonged and covered above with hair of the same colour as that of the body, but naked and flesh-coloured at its extremity (which is flattened) and underneath. Eyes very small, of a dull lead colour.

The colour of the individual dissected by Mr. Yarrell was rusty reddish-brown, with indications of lighter spots and horizontal lines on the ribs, flanks, and thighs. 'These fawn-coloured spots and stripes,' says Mr. Yarrell, 'are common to both species of Tapir' (the Sumatran and the American species then known are meant) 'while young; that of Sumatra not exhibiting till it is six months old any appearance of the well-defined black and white colour which afterwards distinguishes the adult animal.' (*Zool. Journ.*, vol. iv.)

Mr. Bennett, too, remarks that the young is of a much lighter brown than the adult, with numerous small white spots on the cheeks, a whitish muzzle, and six or eight complete narrow bands of white passing along each side of the body from the shoulders to the haunches. 'Regular rows,' says Mr. Bennett, in continuation, 'of small white spots, placed at equal distances from each other, alternate with these bands. The upper parts of the limbs are marked in a similar manner; their inner sides, as well as the under surface of the body, are white; and their extremities of the ground-colour of the whole body, with a few fainter spots scattered over them. Before the end of the first year of their age this livery becomes completely lost: it is partially visible in the young specimen in the Society's museum, but not at all in the living individuals at the Gardens (1830). Similar markings occur in the young of the Sumatran species, and also, we may observe, in that of the Hog in its native state. The adult female of the present species has generally a considerable number of whitish hairs intermingled with the brown, which gives her somewhat of a grizzled appearance.' (*Gardens and Menagerie of the Zoological Society delineated.*)

Locality. South America. 'Few animals of equal size,' says the author last quoted, 'have so extensive a range as the American Tapir. It is found in every part of South America to the east of the Andes, from the Straits of Magellan* to the Isthmus of Darien; but appears to be most common within the tropics. M. Roulin dwells upon it as a singular fact that although it occurs as far as 40° south of the equator, it ceases suddenly at about 8° north, in a situation where it is extremely abundant, and where no adequate cause has yet been assigned to bar its further progress, no large rivers nor lofty mountains intervening, nor any change in the character of the vegetation of the country being manifest. The left bank of the Atrato near its mouth, and the part of Darien inhabited by the independent Indians, may be considered as its northern limit. Its highest range, in the province of Maraquita at least, appears to be from 3000 to 3600 feet above the level of the sea, while the new species discovered by M. Roulin is only met with at a much greater elevation.'

Habits, Chace, &c. The inmost recesses of deep forests are the chosen haunts of this species, which is not gregarious, and flies from the proximity of man. It is for the most part nocturnal in its habits, sleeping or remaining quiet during the day, and at night seeking its food, which, in its natural state, consists of shoots of trees, buds, wild fruits, &c. If we are to believe D'Azara, and he was an accurate observer, it is very fond of the barréro, or nitrous earth of Paraguay. It is however a most indiscriminate swallower of everything filthy or clean, nutritious or otherwise, as the farrago found in the stomach of the individual dissected by Mr. Yarrell showed. Pieces of wood, clay, pebbles, and bones are not unfrequently taken out of the stomachs of those which are killed in the woods; and one kept by D'Azara gnawed a silver snuff-box to pieces and swallowed the contents.

It is a powerful animal, and everything in the underwood of the forest gives way to its rush. It is in the habit of making runs or roads through the brushwood, and these beaten tracks are usually selected by travellers in passing through the forests.

Quiet and peaceable in its demeanour, it is hunted for the sake of its tough hide and its flesh, which, though not liked by the European (for it is coarse and dry), is relished by the unsophisticated palate of the Indian.

The lasso is not often employed in its capture, not only from its haunts being generally unfavourable to that mode of hunting, but because its determined rush and strength will at a single effort snap the line which is strong enough to arrest the career of a bull. The hunters will sometimes lie in wait with their dogs near a Tapir's road as evening approaches, and so get between him and the water to which he usually directs his course for the purpose of bathing and wallowing at the commencement of his nocturnal career. He makes a good fight and inflicts severe wounds upon the dogs with his teeth, especially if he can reach the water, where he stands at bay, breast deep and defies the fiercest of them; for as they are compelled to swim to the attack, the Tapir bides his time, and seizing them by the backs of their necks as they successively come within his reach, shakes them off, not without biting a piece out.

* Apparently not at present.

But it would seem that the most common method of catching them is by imitating their sharp but not very shrill whistle, and thus bringing them within shot of the Indian's poisoned arrow.

Lieut. Maw, who, as we have above seen, brought a young animal of this species to England, speaks of it as feeding upon herbs and the branches of trees, and going much into the water, walking along or rather perhaps across the bottoms of rivers. 'It possesses,' says Lieut. Maw, 'great strength, particularly in the fore part of the body; but is harmless, except when attacked. It is said to pass directly through the thickets without following any previous track.* We were told that when the Tapir is attacked by a Tiger' (*Felis Onça*) [Leopard, vol. xiii., p. 435], 'the Tiger generally springs upon the Tapir's back, when the latter rushes into the woods and endeavours to kill the assailant by dashing him against some large tree. Although strongly and apparently heavily made, the Tapir is said to be fleet.' (*Journal of a Passage*, &c.)

This species is mild in captivity and easily domesticated. Sonnini states that several tame Tapirs are permitted to go at liberty through the streets of Cayenne, and to wander into the woods, whence they return in the evening to the house where they are kept and fed. He adds that they are capable of attachment to their owner, and expresses his opinion that care and attention might convert its qualities of strength, docility, and patience to account as a beast of burthen.

American Tapir.

Fossil Tapirs.

Dr. Buckland, in his *Reliquiæ Diluvianæ*, notices the remains of Tapir in company with those of rhinoceros, elephant, horse, ox, deer, hyæna, bear, tiger, fox, wolf, mastodon, hog, and beaver, in the Val d'Arno, on the authority of Mr. Pentland; and in his interesting and instructive first plate illustrative of his *Bridgewater Treatise* figures a Tapir in little among the mammalia of the first period of the Tertiary series (Eocene of Lyell). In the Epplesheim sand (Miocene of Lyell), Professor Kaup found two species larger than those now living.

It should be borne in mind that the second or Miocene system of tertiary deposits contains a mixture of the extinct genera of lacustrine mammalia of the first or Eocene series, with the earliest forms of existing genera. M. Desnoyers first noticed this in the Faluns of Touraine, where the remains of *Palæotherium*, *Anthracotherium*, and *Lophiodon* were found mixed with the bones of the tapir, mastodon, rhinoceros, hippopotamus, and horse. These remains were fractured and rolled, and sometimes covered with flustra, and must, Dr. Buckland observes, have been derived from carcasses drifted into an æstuary or sea.

Von Meyer records the following species: *Tapir Avernensis*, Croiz. and Job., from the diluvium, Puy-de-Dôme, Cussac; *Tapir Mastodontoides*, Harlan, from Kentucky, with a justifiable query, whether it is a Tapir at all;† and *Tapir Priscus*, Kaup, from the Epplesheim sand. He also alludes to other remains noticed in the works of Fischer, Clift, and Eichwald. (Diluvium, Irawadi.)

Dr. Lund, in his 'View of the Fauna of Brazil,' states that he had in vain looked for either remains or foot-prints of the living Tapir; whence he concludes, that it does not take refuge in caves: but he says that he is in possession of fossil bones which evidently belong to the genus, though they are too imperfect to determine their relation to the recent animal.

TAPPING, or Paracentésis (in Surgery), is the operation usually employed for the removal of fluid from any of the serous cavities of the body in which it has collected in a dangerous quantity. It is accomplished by means of an instrument called a trocar, and a tube, or canula, in which it exactly fits. The trocar is of steel, cylindrical through the chief part of its length, and terminated by a three-sided pyramid which ends in a very sharp point. The canula being placed upon its shaft, the trocar is thrust into the cavity containing the fluid, and being then withdrawn through the canula, the latter is retained in the aperture till all the fluid is discharged. The diseases for which tapping is chiefly performed are ascites, hydrothorax, hydrocele, and, occasionally, hydrocephalus, and effusions of fluid in the pericardium.

TAPTY. [Hindustan, p. 211.]

TAPUH. [Sooloo Archipelago.]

TAR, a well-known empyreumatic product.

The properties of tar are, that it is a viscid brown semi-fluid mass, which long preserves its softness. If it be mixed with water, it acquires a yellow colour and the taste of tar, with slightly acid properties; this solution is well known by the name of tar-water, and has been used in medicine. Tar is soluble in alcohol, in æther, and in the fixed and volatile oils.

If tar be distilled with water, there passes over a brown liquid which consists of much empyreumatic oil and some oil of turpentine; this product is called oil of tar; by redistillation with water it becomes colourless; the substance remaining in the still is pitch; so that, in fact, tar is a mixture of oil and pitch.

Within a few years, tar has been subjected to a minute examination by Reichenbach, who has obtained from it a variety of substances possessing very different properties; the most important of these is creasote. [Creasote.]

After what has been stated of the many different compound substances of which tar is constituted, no exact analysis could of course be stated; its chief constituent is carbon, combined with hydrogen and oxygen, and a small portion of azote.

TAR (French, *Goudron;* German, *Theer;* Italian, *Catrame;* Spanish, *Alquitran;* Polish, *Smola Gesta;* Russian, *Degot, Smola shitkaja;* Swedish, *Tjära*), is obtained from wood or coal by distillation in close vessels, or in piles from which the air is excluded. Pitch (French, *Poix;* German, *Pech;* Italian, *Pece;* Spanish, *Pez;* Russian, *Smola gustaja*) is commonly obtained by the inspissation of tar, or by boiling it until all the volatile matters are driven off. For the chemical properties of tar, see the preceding article.

Tar is extensively manufactured from the roots and branches of pines and firs in Norway, Sweden, Germany, Russia, North America, and other countries in which those trees abound; but that made in the north of Europe is considered far superior to what is produced in the United States. The process usually followed is described in Dr. E. D. Clarke's 'Travels in Scandinavia,' and is, he states, similar to that which, according to Theophrastus and Dioscorides, was practised by the ancient Greeks. He observes indeed that 'there is not the smallest difference between a tar-work in the forests of Westro-Bothnia and those of ancient Greece.' After describing the noble forests which cover the soil down even to the water's edge, about the inlets of the Gulf of Bothnia, Dr. Clarke says, 'From the most southern parts of Westro-Bothnia to the northern extremity of the Gulf, the inhabitants are occupied in the manufacture of tar, proofs of which are visible in the whole extent of the coast. . . . . The situation most favourable to the process is in a forest near to a marsh or bog; because the roots of the fir, from which tar is principally extracted, are always most productive in such places. A conical cavity is then made in the ground (generally in the side of a bank or sloping hill), and the roots of the fir, together with logs and billets of the same, being neatly trussed in a stack of the same conical shape, are let into this cavity. The whole is then covered with turf, to prevent the volatile parts from being dissipated, which, by means of a heavy wooden mallet, and a wooden stamper worked separately by two men, is beaten down and rendered as firm as possible above the wood. The stack of billets is then kindled, and a slow combustion of the fir takes place,

* But see above.

† Professor Owen believes this so-called Tapir to be the young of *Mastodon giganteus*.

without flame, as in making charcoal. During this combustion the tar exudes; and a cast-iron pan being at the bottom of the funnel, with a spout which projects through the side of the bank, barrels are placed beneath this spout to collect the fluid as it comes away. As fast as the barrels are filled, they are bunged and made ready for exportation.' 'From this description,' he adds, 'it will be evident that the mode of obtaining tar is by a kind of distillation *per descensum*; the turpentine, melted by the fire, mixing with the sap and juices of the fir, while the wood itself, becoming charred, is converted into charcoal.' The process of tar-making in Sweden, north of the Bothnian Gulf, has been more recently described in Laing's 'Tour in Sweden,' in which work it is stated that fir-trees which are stunted in growth, or from their situation unsuitable for the saw-mill, are prepared for this purpose by peeling off the bark to the height of one or two fathoms up the stem. This is done by degrees, so that the tree may not decay and dry up at once, but may remain for five or six years in a vegetative state,—alive, but not growing. The sap, thus checked in its circulation, makes the wood richer in tar, so that, when cut down, the tree is almost entirely converted into the substance from which tar is distilled. The roots, rotten stubs, and scorched trunks of trees felled in clearing land, are all applied to the purpose of producing tar. It is stated, in the last-mentioned work, that the state of the weather during the process of burning or distilling greatly affects the amount of produce. The labour required to convey the tar from the forests to the rivers is often very great; and not unfrequently the barrels are committed to the stream in order to pass rapids or falls.

In some parts of France and Switzerland tar is extracted in a kind of oven or kiln, built of stone or brick, in the form of an egg, with its smaller end downwards. These kilns are sometimes as much as ten feet deep and six feet in diameter; and they are provided with a gun-barrel or tube at the lower end to conduct the tar, as it is made, to vessels placed to receive it. The wood is cut into billets, and freed from its bark; and the kiln is filled with bundles of billets, chips being inserted to fill up the interstices. A layer of chips is also placed at the top of the kiln, which, when charged, is covered over with flat stones, so arranged as to form a kind of vaulted chimney. Fire is applied to the dry chips at the top, through an opening left in the centre, and, as soon as the pile is fairly lighted, the chimney is closed in with a large stone, and wet earth is heaped upon the top of the kiln until the escape of smoke is effectually prevented. It is however necessary occasionally to refresh the fire by the admission of a little air through holes in the sides of the kiln. The average product of tar is stated to be from ten to twelve per cent. of the weight of the charge; but the red wood and the knots furnish about one-fourth of their weight of tar. By this plan the wood is charred more equally, and the tar is of superior quality. A considerable quantity of lamp-black collects upon the stones which form the roof and chimney of the kiln, and this is removed after each operation. Probably a still better plan would be to distil the wood in close retorts, similar to those used in the manufacture of coal-gas; but any such apparatus is unsuitable for the wild forest districts in which tar is principally made.

The great importance of tar and pitch as naval stores enabled the Tar Company of Sweden, in 1703, to put England to considerable inconvenience, by refusing to supply those articles excepting at their own price, in such quantities as they might choose, and in Swedish shipping. This circumstance induced parliament to offer bounties for the importation of these and other naval stores from the British colonies in North America, a measure which produced highly beneficial results. It was computed at that period that the annual consumption of foreign tar and pitch in Great Britain and Ireland was about 1000 lasts, and that of other European countries about 5000 lasts, of which four-fifths was tar; and it was stated that besides Sweden, which afforded the chief supply, considerable quantities were made in Norway and in Russia. Probably this estimate was much too small; for Anderson states that in 1730 the quantity of tar annually shipped from Archangel in Russia was computed to be 40,000 lasts. The American war of independence, by interrupting the trade between England and North America, revived the former difficulty respecting the supply of tar, and led to the establishment of the manufacture of tar from pitcoal; an object which had been previously attempted. Becher, a foreign chemist, who lived about the time of Charles II., is supposed to have been the first to propose the making of coal-tar; and it was made for many years in the bishopric of Liege, and in other parts of Germany; the coal being distilled in a kind of still formed of cast-iron. No. 228 of the 'Philosophical Transactions' (vol. xix., p. 544), which was published in May, 1697, contains an 'Account of the making (of) pitch, tar, and oil out of a blackish stone in Shropshire, communicated by Mr. Martin Ele, the inventor of it.' The mineral used is described as a blackish porous rock, lying over the strata of coal, in Broseley, Bently, Pitchford, &c.; and the bituminous part was separated by breaking the rock to powder, and boiling it with water. About the year 1779, in consequence, as before stated, of the American war, some lamp-black manufacturers at Bristol turned their attention to the manufacture of tar from pit-coal; and in 1781, Lord Dundonald, a nobleman distinguished for his scientific pursuits, obtained a patent for improvements upon the process previously followed. Mr. Pitt, of Pendeford, near Wolverhampton, in a letter addressed to the Society of Arts, in 1790, on the subject of converting the smoke of steam-engine furnaces into tar, alludes to three establishments at Bradley, Tipton, and Dudley Wood, erected by Lord Dundonald and the gentlemen associated with him; and states that the business was then carried on with success. 'These tar-works,' says Mr. Pitt, 'are erected in the vicinity of large iron and coal works: the iron-masters furnish the tar-works with raw coal *gratis*, and receive in return the cokes produced by such coal; and the proprietors of the tar-works have the smoke only for their labour and interest of capital.' (*Transactions of the Society of Arts*, vol. ix., p. 132.) The process adopted at these works is fully detailed by Mr. Pitt. The manufacture of coal-tar has not proved so important as was at one time anticipated, although for some purposes it is deemed superior to that made from wood. The author of the article 'Navy,' in the *Supplement to the Encyclopædia Britannica*, considers tar from sea-coal to be an important resource in case of England being compelled to revert to her own resources for naval stores; and observes that for painting or tarring wood-work of every kind, it is said to stand exposure to the weather better than the common tar. He also refers to the pitch-lake of Trinidad [TRINIDAD] as a source whence an almost inexhaustible supply of mineral pitch and tar might be obtained. Tar is produced in large quantities in the manufacture of coal-gas; but in some districts its value is considered so trifling that it is mixed with the fuel by which the retorts are heated. It is usually separated from the gas by condensation; but the introduction of a quantity of brushwood into the condenser, so as to form a mechanical interruption to the passage of the gas, is found greatly to assist the operation.

The import duty upon tar has been for some years past 12*s.* per last,* if from British possessions, and 15*s.* if from foreign countries; but under the new tariff of Sir Robert Peel (1842), it is respectively 6*d.* and 2*s.* 6*d.* per last. The quantity imported in the five years from 1835 to 1839, was 60,622 lasts, or about 12,124 lasts per annum; of which 58,106 lasts, or 11,621 lasts annually, were entered for home consumption. During this period the duty amounted to 44,023*l.*, or upon an average 8804*l.* per annum. Of the above quantity Russia furnished about 50,155 lasts; the United States, 6446 lasts; Sweden, 2297 lasts; Denmark, 1300 lasts; and Norway, 348 lasts; the remainder being made up of small quantities from Germany, Prussia, &c.

Pitch is extensively manufactured in Great Britain, yet the quantity imported in 1829 is stated, by M'Culloch, to have been about 10,752 cwt. The duty is 10*d.* per cwt., if from foreign countries, and 9*d.* if from British possessions; or, under the new tariff, 6*d.* and 1*d.* per cwt. respectively.

TARA. [SIBERIA.]

TARABLOUS. [SYRIA.]

TARAI. [HINDUSTAN, p. 217.]

* A last is twelve barrels, and each barrel is, by the Custom-House regulations, to contain not more than thirty-one gallons and a half.

TARAKAÏ is the name of a large island, which has long figured on our maps under the name of Saghalien or Saghalian, and has at different times been supposed to be called Tchoka, Karafto, and Sandan. This island extends from south of 46° to 54° 20′ N. lat., more than 600 miles in length, but the width is various. Towards the southern extremity, north of the Bay of Aniva, it is nearly 100 miles wide, but it soon contracts to about 25 miles, which is about its average width as far north as the Bay of Patience, where it suddenly expands to 120 miles, Cape Patience running far out into the Pacific. From this point (49° N. lat.) northward the island again grows narrower, but very gradually, so that at 51° N. lat. it is still nearly 80 miles wide. Farther north its average width does not exceed 50 miles. The area of the island probably exceeds 30,000 square miles, which is not much more than that of Scotland, if we include the islands.

Tarakaï extends along the eastern coast of Asia between 142° and 145° E. long., and is separated from the continent by a strait, which is called the Gulf of Tartary, because the country of the Mantchoos for a long time was known by the name of Tartary. This gulf or strait is 200 miles wide at its most southern extremity, but it grows narrower as we advance farther north, until near 51° 30′ N. lat. it is less than 40 miles wide. So far this sea has been navigated, but at that point a shoal extends across the gulf, on which there is only water for boats. That portion of the gulf which lies between 51° 30′ and 52° 30′ N. lat. is not known. Krusenstern thinks that this part of the island of Tarakaï is united to the continent of Asia by an isthmus, but La Perouse expressly states that dried fish is carried from the western shores of the island to the river Amur in boats, which could not be done if the isthmus of Krusenstern existed. It may appear strange that these two navigators have not been able to decide this point, as one sailed up from the south to 51° 30′, and the other from the north to nearly 53° N. lat., but they found the sea always covered with thick fogs, and hardly ever could see a few miles before them, and the water shoaled so suddenly and constantly that they did not think it advisable to proceed farther. If an isthmus exists, it must be near 52° 30′ N. lat., where a low sandy cape certainly stretches so far to the east as to approach very near the western shores of the island. North of this narrow and shallow part, the gulf presents a circular basin, about 50 miles wide, which receives the waters of the river Amur, and is therefore called by Krusenstern the Liman of the Amur. This basin is united with the sea of Okhotzk by a strait, which in the narrowest part is about ten miles wide. It does not appear that there is any current in this gulf, which is in favour of the opinion of Krusenstern. The southern extremity of Tarakaï is divided from the island of Yeso by the Strait of La Perouse, which, between Cape Crillon on Tarakaï and between Cape Soja on Yeso, is hardly thirty miles wide, and in which the tides run with great velocity. La Perouse, who visited the Gulf of Tartary in June, found that southern winds were blowing nearly uninterruptedly; but Broughton, who was there in September, experienced eastern and north-eastern winds.

Though the coast of the island is of great extent and much indented, it does not appear that there are many good harbours. Along the western shores only open roadsteads have been found. At the southern extremity of the island, between Cape Crillon and Cape Aniva, is a wide open bay, the Bay of Aniva, which is enclosed by two projecting tongues of land, and extends 50 miles from south to north. There is good anchorage at its most northern extremity. The projecting headland, which occurs near 49° N. lat., on the eastern side of Tarakaï, and terminates with Cape Patience, encloses the Bay of Patience, which is very extensive, but open and exposed to eastern and southern winds. At the most northern extremity of the island is the Northern Bay, between the cape of that name and Cape Mary. It is not very large, and offers in several places good anchorage and shelter.

The island is naturally divided into three tracts: the mountainous, which occupies the southern portion; the level, in the middle; and the hilly tract, which extends over the northern districts. The mountain-region is the largest, and comprehends more than one-half of the island, terminating on the north at Cape Dêlisle de la Croyère (near 51° N. lat.). A chain of mountains begins at Cape Crillon, and continues in an uninterrupted line northward to an elevated summit called Peak Bernizel, where it seems to be united to another and lower chain, which traverses the eastern peninsula, and incloses the Bay of Aniva on the east. Cape Aniva is formed by a high isolated hill, which is connected by a low isthmus with the chain of hills which lies farther north, and joins the principal range at Peak Bernizel. Farther north occur other summits, as Peak Lamanon, Peak Mongez, and Mount Tiara: the two last mentioned are north of 50° N. lat. None of these summits have been measured, but their elevation probably does not exceed 5000 feet above the sea-level. Along the western coast the mountains in some places come close up to the water's edge, but a narrow level tract generally separates them from the shore, and this tract is covered with high trees, while the declivities of the mountains are mostly bare, probably owing to the rapidity of their slope. Extensive flats occur at Aniva Bay and the Bay of Patience. The low country which skirts the shore on the eastern side of the mountains appears to be more extensive and less interrupted than that along the western shores. On the eastern side the shore in some places is level and low, and in others elevated. The country extending from 51° to 53° N. lat. is so low that the shores are not visible at the distance of five or six miles, and it is sandy and overgrown with bushes. The interior is in general level, partly sandy and partly swampy, and a great part of it is covered with short bushes or small trees. A number of low sand-hills are dispersed over the country, which are destitute of trees, and appear like islands in a sea of verdure. The hilly tract occupies the most northern part of the island, or that which extends from 53° N. lat. to Cape Elizabeth. The coast is in general high and steep, being generally composed of perpendicular white cliffs. There are only a few tracts in which the coast sinks down to the level of the sea; and here the villages are built. The interior consists of a succession of high hills covered with full-grown trees to the very summits; the valleys which intervene between them are partly wooded and partly covered with a fine close turf. This part of Tarakaï seems to possess a considerable degree of fertility.

Climate.—As European navigators have only occasionally visited this island, and have only stayed there a few days, or at the utmost a couple of weeks, our information respecting the climate is extremely deficient. We only know that even at the beginning of June the higher summits of the mountains have still some snow on them, which indicates that the country must be much colder than Great Britain, which is nearly at the same distance from the pole: otherwise the summer months seem to be temperate, but the continual fogs which enclose the island nearly all the year round are more dense than those that occur on the coasts of Nova Scotia.

Productions.—No kind of grain is cultivated, not even round the settlements of the Japanese, nor are orchards or kitchen-gardens mentioned. The inhabitants however derive profit from the spontaneous products of the soil: they dry the roots of a species of lily for winter food, and collect great quantities of garlic and angelica, which are found on the skirts of the woods. The forests consist of oak, maple, birch, and medlar, but chiefly of fir. Large tracts are covered with juniper-trees. Gooseberries, raspberries, and strawberries abound, and also wild celery and watercresses. It does not appear that wild animals are numerous: only martens and bears are mentioned, and even these do not seem to be common. The sea supplies the inhabitants with the means of subsistence. Salmon is perhaps nowhere so abundant as in the Gulf of Tartary. The account of La Perouse in this respect seems hardly credible. Dried and smoked salmon, together with the skins of salmon, are prepared for the foreign market, and constitute the principal articles of export. Herrings, which are very abundant, are likewise cured and exported. Cod occurs, but it does not seem to be taken to such an amount as to form an article of export. Whales are numerous in the Strait of La Perouse and along the eastern coast, and train-oil in bladders is an article of export. In the same parts seals, fur-seals (*Phoca ursina*), sea-lions (*Phoca jubata*), and sea-otters (*Lutra marina*) are very frequent. No mines are worked.

The inhabitants are aborigines, among whom a few Japanese have settled on the Bay of Aniva, and a few Mantchoos on the Northern Bay. In the Japanese settlements are a few Japanese officers, but no Chinese authorities have been

seen, nor is this island enumerated among the possessions of the Chinese. The aborigines call themselves *Aïnos* (*i.e.* men), and are at present known under that name as a nation. This nation extends northward to the peninsula of Kamtchatka, of which it occupies the most southern extremity near Cape Lopatka, and it inhabits the Kurile Islands, the Japanese island of Yeso, Tarakaï, and the coast of the continent of Asia from the mouth of the Amur river southward to the very boundary-line of Corea. They never cultivate the soil, nor apply themselves to hunting wild animals, and they keep no domestic animals except dogs, which they use in winter for drawing their sledges, like the inhabitants of Kamtchatka. La Perouse found them somewhat shorter in stature than Europeans, rarely exceeding five feet six inches, and some hardly five feet. Their countenances are benevolent and friendly; they have tolerably large eyes, thick lips, rather high cheek-bones, and a somewhat broad and compressed nose. Their cheeks and chins are covered with long, thick, black beards: there are many individuals whose body is covered with hair, as occasionally is the case in Europe. The only kind of manufacture among them is a kind of cloth made of the bark of willow-trees, which are very common in the island, and do not seem to differ from the European species. They use in this manufacture a machine. The other articles of cloth they obtain by barter from the Japanese and Mantchoos. They show also some skill in the erection of their huts and the building of their boats. Their huts are of wood, covered with the white bark of birch, and have a roof of wood thatched with dry straw. La Perouse compares them with the cottages of the peasants of France. Their boats are of large size and strongly built. Some of their costumes are evidently adopted from the Chinese, as the practice of letting their nails grow to a considerable length, and their mode of saluting by prostration. Like them, they sit on mats, and eat with little sticks. Their language does not resemble either that of the Japanese, Chinese, or Mantchoos. The Mantchoos visit the northern and western coast to barter dried and smoked salmon, and dried herrings, for some nankeens, tobacco, and utensils. The Japanese visit the southern and eastern districts, where they obtain train-oil, herrings and salmon, and a few furs, and give in return lacquered wooden eating and drinking vessels, tobacco and tobacco-pipes, kitchen utensils, rice, coarse cotton-cloth, and some minor articles.

TARANTA'SIA, or TARANTAISE. [Savoy.]

TARANTISMUS is the name given to a peculiar nervous affection which was long supposed to be the consequnce of the bite of the Tarantula Spider. It seems to have occurred frequently in the kingdom of Naples during the sixteenth century, and to have been nearly similar in its characters to the disease which was originally called St. Vitus's dance [Chorea], and to that which has occasionally prevailed in parts of Scotland, and has been called the 'leaping ague.'

The patients, nearly all of whom were women, soon after being bitten (as it was supposed) used to fall into a profound stupor, from which nothing roused them but the sound of such music as pleased them, on hearing which they had an irresistible desire to dance. So long as the music continued, and was in tune and sufficiently lively, they would go on jumping and dancing till they felt exhausted; and, all the time, some used to shriek, some to laugh and sing, some to weep. When, after a short rest, they had recovered from their fatigue, they would again begin to dance with as much vigour as before, unless the music were played slowly or confusedly, when they would stop and grow anxious and melancholy, or even, if the music were not soon made agreeable to them, would fall into a dangerous state of stupor. The disease used to last about four days, and seemed to be cured by the profuse perspirations brought on by the active exercise; but it often returned at the same time in the following year, or even for a succession of years, and on every occasion required the same treament.

Since it has been found that the bite of the Tarantula can produce no such strange effects as these, many have suspected that the disease ascribed to it never really existed, but was feigned for the purpose of exciting pity or for the pleasure of dancing. There is good reason to believe that in most instances it was merely counterfeited: but there can be no doubt that such a disease had occurred and had given occasion to the practice of the fraud. Besides its similarity to diseases whose reality is generally admitted, such as the St. Vitus's dance and the leaping-ague, cases have occasionally been met with in recent times which closely resemble it, and in which there could be no just suspicion of fraud. Such a case is described by Mr. K. Wood, in the seventh volume of the 'Medico-Chirurgical Transactions;' another is recorded by Mr. Crichton, in the 31st volume of the 'Edinburgh Medical and Surgical Journal;' and in the 'Cyclopædia of Practical Medicine,' art. 'Chorea,' several cases of analogous affections are related. All these however occurred singly. That the Tarantismus and the St. Vitus's dance should have assumed the characters of epidemics may be ascribed to their propagating themselves, as all convulsive affections are apt to do among nervous and superstitious persons, by the propensity to imitation, the effects of which are still frequently seen in the production of hysteria, chorea, and other similar diseases.

TARANTO, a town of Apulia, in the kingdom of Naples, in the administrative province of Lecce, or Terra d'Otranto. It is an archbishop's see, and the head town of a district: it contains 18,000 inhabitants. It occupies only a small part of the site of the antient Tarentum, being confined to the island or peninsula at the entrance of the inner harbour or Mare piccolo, on which formerly stood the fortress or acropolis of Tarentum. There are few remains of the antient town. Modern Tarento is ill built: it is fortified and has a castle, several churches and convents. It carries on some trade by sea in small craft. It has also some manufactures of linen and of 'pinna marina,' the name of a kind of mussel or shell-fish, the silky filaments of which are woven into gloves and other articles. A part of the population is employed in fishing. Excellent oysters are found on the coast. The inner port is nearly filled up, but the outer or large port is accessible to vessels of good size, and is protected by two islands which are situated at the mouth. Taranto has the advantage of being the only safe harbour in that part of the eastern coast of Italy which extends from Messina to Cape Leucas. The large gulf which lies between the coast of Calabria and the Iapygian peninsula is called the gulf of Taranto. Much wool is grown in the neighbourhood of Taranto. Two lagoons, one of them of considerable extent, which lie south-east of the town, and which communicate with the sea, yield a great quantity of salt by evaporation. The district of Taranto contains above 87,000 inhabitants. [Otranto, Terra di.] (Neigebaur; Serristori; Afan di Rivera, *Considerazioni sulle due Sicilie;* Petroni, *Censimento dei Reali Dominj.*)

Antient Tarentum, the Taras (Τάρας) of the Greeks, was one of the principal, or rather the principal Greek city on the east coast of Italy. It is said to have been a town of the Messapians, to which were joined some Cretan colonists from the neighbouring town of Uria. About 694 B.C., according to the story, Phalantus, one of the Partheniæ, or illegitimate sons of the Spartan women born during the absence of their husbands in the first Messenian war, having left his country with a number of others of the same condition, arrived on the coast of Iapygia, took Tarentum, and expelled the original inhabitants. He organized the new colony, and remained at the head of it until he was expelled by an insurrection, and withdrew to Brundusium, where he died. (Justin, iii. 4.) A war between the Tarentines and the Iapygians ensued, in which the people of Rhegium assisted the Tarentines, but they were defeated by the Iapygians, who destroyed a great number of the Tarentines. (Diodorus, xi.) Tarentum however recovered from its losses, and it flourished by commerce, acquired a considerable extent of territory, and became the most powerful city of Magna Græcia. Heraclea was a colony of Tarentum. Herodotus (iii. 136) mentions Aristophilides as king of Tarentum in the time of Darius Hystaspes. The government however underwent several changes, and Strabo (vi. 193) speaks of Tarentum as being at one time a democracy. Archytas, a native of Tarentum, is said to have made a body of laws for the Tarentines. [Archytas.]

About 338 B.C. the Tarentines, being engaged in war with their neighbours the Lucanians, applied to Sparta

for assistance. Archidamus, the son of Agesilaus, was sent to them, and he was killed in fighting on their side. Some years after, being hard pressed by the Lucanians and Bruttii, the Tarentines applied to Alexander, king of Epirus, and uncle to Alexander the Great. He came to Italy with troops, obtained considerable advantages, but was at last surprised and killed by the Bruttii, near Pandosia, B.C. 323. (Justin, xii. 2; Livy, viii. 24.). The Tarentines had by this time degenerated; like most of the Greeks on the Italian coast, they had become luxurious and effeminate. Ælian (*Var. Hist.*, xii. 30) speaks of their habit of drinking early in the morning, and their appearing intoxicated in the forum.

In the year 282 B.C. the Romans, after having conquered the Samnites, made war upon the Lucanians. The Tarentines, who saw with jealousy the encroachments of Rome, unexpectedly attacked a Roman fleet, commanded by the Proconsul L. Valerius, which was sailing near their coast, and killed a great many of the crew. The Roman senate sent commissioners to demand reparation for the outrage, but the Tarentines treated them with insult. Aroused however to a sense of their danger, they applied to Pyrrhus, king of Epirus, for assistance, and sent vessels to convey him over with his troops, B.C. 281. Pyrrhus soon found that the Tarentines were too effeminate to give him much support, and he was obliged to assume a dictatorial power in order to enforce something like order and obedience among them. Chiefly with his own troops, he carried on the war against Rome for several years, but was at last defeated by the consul M. Curius Dentatus, and obliged to re-embark for Epirus; leaving however a garrison in Tarentum, B.C. 275. [PYRRHUS.] The Tarentines having shortly after quarrelled with the Epirote garrison, applied to the Carthaginians for assistance to drive away the Epirotes. The Romans having had notice of this negotiation through Milo, the Epirote commander, sent the consul L. Papirius Cursor, who took Tarentum, and allowed the Epirote garrison to return home. It appears however from Livy (*Epitome*, xv. 1) that the Tarentines, though treated with severity, were placed in the condition of allies of Rome, which they continued to be till after the battle of Cannæ, when Hannibal, who occupied Campania and Apulia, began to carry on secret intelligence with some of the Tarentine chief citizens, who were dissatisfied with their forced Roman alliance.

In the year 212 B.C. the hostages of the Tarentines ran away from Rome, but being pursued and overtaken near Terracina, they were brought back, and after being beaten with rods were thrown down the Tarpeian rock. This cruel punishment irritated the people of Tarentum, an agreement was made with Hannibal, and his troops were admitted into the city by night. The Roman garrison stationed in the citadel was besieged by sea and by land. The example of Tarentum was followed by Metapontum and Thurium. The Roman garrison in the citadel of Tarentum defended it most gallantly, although they suffered greatly from want of provisions. An attempt which was made to introduce supplies by vessels from Sicily was defeated by the Tarentine squadron under Democrates, with the loss of several Roman ships. In 209 B.C. the consul Q. Fabius Maximus retook Tarentum by surprise, and through the treachery of the garrison left by Hannibal, which consisted of Bruttian auxiliaries. The Tarentines made only a slight defence. Nico, Democrates, and Philomenus, the leaders of the party which was hostile to Rome, fell during the assault. A great booty was made by the Romans, said to be nearly equal to that made at the taking of Syracuse. But the consul Fabius abstained from taking the statues of the gods, saying he would leave to the Tarentines their angry deities. (Livy, xxv. 7, 11; xxvi. 39; and xxvii. 15, 16.)

From that time Tarentum remained in subjection to Rome; and although it greatly declined in wealth and importance, it was still a considerable place in the time of Augustus. Horace calls it 'molle Tarentum' (*Satir.*, ii. 4), and 'imbelle Tarentum' (*Epist.*, i. 7). The Greek language and manners were retained by the inhabitants even after the fall of the Western Empire. Tarentum was one of the chief strongholds retained by the Byzantine emperors in Southern Italy. About A.D. 774, Romualdus, the Longobard duke of Beneventum, took Tarentum from the Byzantines. The Saracens landed at Tarentum about A.D. 830. The town was afterwards several times taken and retaken and sacked, and it was during this period that the old town on the mainland was abandoned, and the inhabitants retired to the island as being more fitted to their reduced numbers, and also better capable of defence. At the breaking up of the Longobard state of Beneventum, Tarentum was for a time a separate principality, like Capua and Salernum. In the eleventh century it was taken by the Normans with the rest of Apulia, and Robert Guiscard made his son Bohemund prince of Tarentum. Under the Suabian dynasty, Frederic II. gave the principality of Tarentum to his illegitimate son Manfred. Charles II. of Anjou gave it to his younger son Philip, whose descendants acted a considerable part in the civil wars of the kingdom of Naples under Joanna I. Tarentum came afterwards into the possession of the powerful family of the Orsini, upon whose extinction it reverted to the crown.

(Giannone; Giovani, *De Antiquitate et varia Tarentinorum Fortuna;* D'Aquino, *Deliciæ Tarentinæ Libri IV.*, Naples, 1771.)

TARARE. [RHÔNE.]

TARASCON, a town in France, in the department of Bouches du Rhône, 452 miles south-south-east of Paris, by Auxerre, Lyon, Valence, Le Pont St. Esprit, and Beaucaire; and 48 miles west-north-west of Aix, the capital of the department.

Tarascon is mentioned by Strabo, who writes the name Ταράσκων, and by Ptolemy, who writes it Ταρουσκών; but it appears to have been of little importance in antient times. Under the counts of Provence, to whom in the middle ages it was subject, it was of more consequence from its frontier-position. It had a castle at least as early as A.D. 1251; of which the present castle occupies the site. This latter was built, according to Millin, by Louis II. of Anjou, count of Provence (A.D. 1384-1417); but according to other authorities Charles II. *le Boiteux* (A.D. 1285-1309) commenced the structure and Louis finished it. It is popularly called 'Château du Roi Réné' ('King Réné's Castle'), but it was undoubtedly erected before his accession.

The town is on the left bank of the Rhône, immediately opposite Beaucaire, on a rocky site sufficiently elevated above the bed of the river to secure it from inundation. The communication with Beaucaire was antiently by a stone bridge; a mass of stone-work, the remains of this bridge, lately existed, and probably still exists, in the middle of the river, between the two towns; the rest of the bridge had been swept away by the stream. In later times the communication was by two bridges of boats, extending one from each bank to this fragment of the old bridge. Within the last few years a suspension bridge of iron-bars has been constructed.

Tarascon is surrounded by an old ruined wall flanked with towers, and is entered by three gates. Some of the streets are straight and tolerably wide. The castle is a picturesque Gothic building of freestone in pretty good preservation: from the platform on the top of the castle there is an extensive view along the valley of the Rhône. Sainte Marthe (Martha) is the principal church in the town; in the crypt is a monument with a marble statue apparently sculptured early in the 16th century, and shown as the monument of Sainte Marthe. In the same church is the uncouth figure of a monster called the Tarasque, which, according to the legend, fed on human flesh and haunted the banks of the Rhône between Arles and Tarascon, and was overcome by Sainte Marthe. This figure is paraded through the city on Whit-Monday amidst the shouts of the idlers of the place, whose riotous behaviour frequently leads to serious accidents: it also makes part of the procession on the festival of Sainte Marthe. These customs, which had been disused after the Revolution, were renewed under the empire of Napoleon, if not before. There are a town-hall, a court-house, a commercial court (*Tribunal de Commerce*), two hospitals, a theatre, barracks, and abattoirs, or public slaughter-houses; these are most of them, if not all, modern buildings.

The population of the commune, in 1831, was 9225 for the town, or 10,967 for the whole commune. The neighbourhood of the town is very fertile, and a considerable trade is carried on in corn, wine, and oil; the townsmen are engaged in throwing silk and spinning cotton-yarn, and in manufacturing hussars' and grenadiers' caps, hats, brandy, vinegar, and starch; there are tan-yards and cooperages. There are three fairs in the year. The industry of the inhabitants and their lively temperament

impart to the place an air of life and activity which contrasts remarkably with the ordinary dulness of Beaucaire.

Tarascon has a communal college or high school and a public library of 2000 vols.: it was the birth-place of Leon Ménard, the antiquary. The town was for a long time after the Revolution the seat of a subprefecture, or capital of an arrondissement; but about the time of the first restoration of the Bourbons, the subprefecture was removed to Arles.

(Vaysse de Villiers, *Itinéraire Descriptif de la France*; Millin, *Voyage dans les Départemens du Midi de la France*; *Dictionnaire Géographique Universel*.)

There is another town in France called Tarascon, in the department of Ariège, and on the river Ariège above Foix: it is from its position sometimes distinguished as Tarascon-sur-Ariège. D'Anville is disposed to identify it with the Tarusconienses of Pliny (*Hist. Nat.*, lib. iii., c. 5, 6), which others would fix at Tarascon on the Rhône. Tarascon-sur-Ariège is a small place, a mart of the ironstone dug in the adjacent Pyrenees. The population is probably about 1500.

TARA'XACUM. [Leontodon.]

TARAZO'NA, a considerable district of Aragon in Spain, bordering on the north and east on the province of Navarre; on the south on the province of Soria; and on the west on the Corregimiento de Borja. The capital, Tarazona, the antient Turiaso, is situated at the foot of a lofty mountain-range called the Moncayo, on the banks of the river Queiles, in 41° 35′ N. lat., 2° 4′ W. long. Tarazona is the see of a bishop, who is suffragan of Saragossa. The town is badly built, and the streets narrow and crooked. With the exception of the cathedral, a fine Gothic pile erected in the thirteenth century, there is no other building worth notice. Miñano (*Diccionario Geografico*, vol. viii., p. 392) estimates the population of Tarazona at 10,000 inhabitants, in 1827. The neighbourhood is well cultivated, and yields abundant crops of all sorts of grain. There is also a small town in La Mancha called Tarazona.

TARBES, a town in France, capital of the department of Hautes Pyrénées, or High Pyrenees: about 400 miles from Paris, in a direct line south-south-west; 453 miles by the shortest road through Orléans, Châteauroux, Limoges, Périgueux, Agen, and Auch: or 533 miles by Limoges, Cahors, Montauban, Toulouse, and Auch, which is the route given by Reichard in his *Itinéraire*. It is in 43° 13′ N. lat. and 0° 5′ E. long.

Tarbes is mentioned in the 'Notitia Provinciarum et Civitatum Galliae,' where it is called Tuba: it was the chief town of the Bigerrones, Bigerri, or Begerri, a nation which has given name to the district of Bigorre. In the town or adjacent to it was a fortress, called, in the 'Notitia,' *Castrum Bigorra*, the site of which is now occupied by the cathedral. In the middle ages, Tarbes was the capital of the county of Bigorre; it suffered from the ravages of the Saracens and the Normans, and was held for a time by the English. There was some sharp fighting near the town, in the campaign of the Duke of Wellington, A.D. 1814.

Tarbes is situated in a fertile plain, nearly 1000 feet above the level of the sea, watered by the Adour (on the left bank of which the town stands) and by the Lechez, and bounded on the south by the Pyrenees. The town is walled; the streets are well laid out, broad, paved, and watered by little brooks or streams, which contribute both to coolness and cleanliness. There are two public places or squares, that of Maubourget, which is planted with trees, and that of Marcadieu, remarkable for its size; beside these two places, there is an agreeable promenade, called Le Prado, outside the walls. The houses in the town are generally of two or three stories, well built, of brick, some of marble, and roofed with slates. They have for the most part good gardens. The principal public buildings are the cathedral; the prefect's office, formerly the residence of the bishop, which from its elevated situation commands a pleasant prospect; and a handsome theatre of quite modern erection. The old castle of the counts of Bigorre is used as a prison. Tarbes has five faubourgs, or suburbs, on the five roads which lead from it in different directions: the suburbs are that of Rabastens on the east, on the right bank of the Adour, which separates it from the town; that of Vic on the north; that of Bagnères on the south; all on the roads leading respectively to those places; that of Sainte Anne on the west, on the road to Pau; and that of Sainte Catherine on the south-west, on the road to Lourdes and Argellez.

The population of the commune, in 1826, was 8712; in 1831, 9706; in 1836, 12,630. There are copper-mills and manufactories for copper utensils, paper-mills, and tanyards; the town is the general mart for the supply of the department; there is a considerable market every fortnight for agricultural produce of every kind and for cattle, much frequented by the Spaniards, who make large purchases of live stock. There is a marble-quarry near the town.

Tarbes has a subordinate court of justice and a commercial court, some fiscal and other government offices; a communal high school with a library, and school buildings of good architecture; a free school of drawing and architecture; an hospital; a society of agriculture; and a government stud, for which there are two large ranges of stables and a handsome riding-school, just outside the town.

The arrondissement of Tarbes has an area of 505 square miles, and comprehends 197 communes: the population, in 1831, was 104,022; in 1836, 110,542; and is divided into eleven cantons, or districts, each under a justice of the peace. The bishopric of Tarbes dates from the sixth century, and now comprehends the department: the bishop is a suffragan of the archbishop of Auch.

(Millin, *Voyage dans les Dép. du Midi de la France*; Malte Brun, *Géographie Universelle*; *Dictionnaire Géographique Universel*.)

TARDI'GRADA, Cuvier's name for the first family of the Edentata, comprising, of living genera, the Sloths only. [Ai; Unau.] The *Tardigrada* form the eighth order in Illiger's method, and comprise the Sloths and *Prochilus*; but the latter cannot be said to have any claim to such a collocation. [Bear, vol. iv., pp. 90, 91.]

TARDI'VOLA, Mr. Swainson's name for a genus of the subfamily Tanagrinæ, and thus characterized by him:—

Bill lengthened, conic, somewhat slender; the sides not gibbous; the commissure slightly or not at all sinuated. Wings very short; the first quill shorter than the four next, which are equal and longest. Tail lengthened, cuneated or graduated. Feet large. Tarsus and toes long. Outer toe rather shorter than the inner. Claws slender, slightly curved.

Example, *Tardivola sphenura*. [Tanagers.]

TARE. We hardly know whether *all* the words *tare*, *tret*, *cloff*, *suttle*, *gross*, *net*, are still used in commerce; they all hold their places in works of arithmetic. *Tare* is said to be the allowance for the weight of the box or bag in which goods are packed; *tret*, an allowance of 4lb. in 104lb. for waste; *cloff*, an allowance of 2lb. in 3 cwt., that the weight may hold good when sold by retail; the *gross* weight, that of the goods and package all together; the *suttle* weight, that which remains when tare only is allowed; the *net* weight, that which remains when all allowances are made. We shall merely state what we know of these words.

Tare (written *tara* in some of our older arithmetical works) is made from the Italian *tarare*, to abate. In that language *tara* is a technical term implying abatement of any kind, not for weight of package only. We believe *cloff* to have been the English word which originally stood for the allowance for package: in our older arithmeticians, tare and cloffe generally go together, and the latter seems to be for the package, the former for other abatements. *Cloff* or *clough* is defined in an old dictionary as that wherein any thing is put for carriage sake. Humphrey Baker (1562) speaks only of tare and cloffe; Masterson (1592), of tara, cloffe, and tret, but the first two terms are used together. We cannot find cloff used in the sense given to it by our modern books of arithmetic until about the end of the seventeenth century.

Tret seems to be from the Italian *tritare*, to crumble. Stevinus, in his Latin treatise on book-keeping, uses *intertrimentum* in the sense of deduction from the quantity charged for. *Gross* weight needs no explanation; the Italian form *netto* was formerly used for net weight. It being well known that these terms generally come to us from the Italian, we must suppose suttle to be from *sottile*, which is used in the sense of fine and valuable, and is applied to the finer part, as separated from the coarser. One of our old writers (Masterson, 'Arithmetike,' 1592) uses suttle weight in a manner which makes us imagine we see the origin of the *hundred* weight being a hundred

and twelve pounds. Without any explanation, as if it were matter of notoriety, he contrasts *suttle* and *averdupois* weight, the former having 100 pounds to the hundredweight, the latter 112. In the rougher sort of goods, at the same period, the tare was (as appears by the tables they give) very often 12 pounds in 112: perhaps then the hundredweight of 112 pounds was only an allowance for the weight of the box, barrel, or other package.

TARES are a most important green crop in the improved systems of agriculture, especially on heavy soils, where they thrive best. When sown in autumn, with a small sprinkling of wheat or rye, they cover the ground in spring, and supply abundance of fodder in summer. A good crop of tares is fully equal in value, if not superior, to one of red clover: it comes off the ground in sufficient time to give the land a hasty summer tillage, which is so useful in destroying weeds, and to allow turnips to be sown in the same season. They smother annual weeds if the crop is plentiful, which should always be secured by an abundant manuring: thus they are a good substitute for a summer fallow in heavy soils, and amply repay the labour and manure bestowed upon them.

There are many species and varieties of tares; but that which is found the best adapted for agricultural purposes is the common tare (Vicia sativa), of which there are two principal varieties, very slightly differing in appearance, one of which is hardy, and will stand the severest winters: the other is more tender, and is therefore only sown in spring; but it has the advantage of vegetating more rapidly, so that spring tares sown in March will be fit to cut within a fortnight or three weeks after those which were sown in autumn. By sowing them at regular intervals from September to May, a succession of green tares in perfection, that is, in bloom, or when the pods are formed, may be cut for several months, from May to October. A prudent farmer arranges his crops so that he shall have artificial green food for his horses and cattle at least six months in the year, by having tares fit to cut between the first and second cut of clover. When there are more tares than is absolutely required for this purpose, and the weather permits, they make excellent hay; or, if the weather is not favourable, they are cut and given to sheep, which are folded on the portion already cut. It is an advantage to have portable racks for this purpose, that the fodder may not be trod under foot and wasted; or the tares may be placed between hurdles, tied two and two, which form extemporaneous racks. It is prudent to raise sufficient seed for another year; but a crop of seed-tares raised for sale is seldom profitable, as they greatly exhaust the soil: and the price varies so much in different seasons, that it becomes too much of a speculation for a farmer. The difficulty in distinguishing the seed of the winter tare from the spring variety is so great, that it should either be raised at home, or only purchased from neighbours, or from the most respectable seedsmen. It is a common practice with dealers to mix the seeds of the winter tares, after the time of sowing is past, with spring tares, which are in request at a later period. The inconvenience of this is, that they do not vegetate equally, and consequently the winter tare is not in bloom when the spring tare is fit for the scythe. Foreign tares, which are imported in large quantities, are often the growth of southern climates, and will not stand the winter; or they have been raised from seed sown in spring, so as to be really spring tares. The difference is probably more owing to habit than to any real botanical distinction between them. When spring tares are sown in autumn instead of winter tares, they may occasionally stand the frost, if not very severe; but, in general, they rot on the ground and never recover; whereas the real hardy winter tares, whose vegetation is slower, seem insensible to the severest frosts.

In the early part of summer green rye and tares, mixed, are sold at a great price in large towns, for horses which have worked hard and been highly fed in winter. They act as a gentle laxative, and cool the blood: near London, where every produce is forced with an abundance of manure, tares are often fit to cut early in May, and the land is immediately ploughed and planted with potatoes, or sown with mangel wurzel or ruta baga, which come off in September or October, in time for wheat-sowing. Thus two very profitable crops are raised during the time that the land, according to the old system, would have been fallow; and at the same time it is left as clean, by careful hoeing, as the best fallow would have made it.

There are a great many species of tares or vetches, for the terms are synonymous, many of which have been proposed to be introduced into general cultivation; but none seem, on the whole, to be so well adapted to our climate as the common tare: some have biennial and some perennial roots. The *Vicia biennis* has a strong stem and large leaves, and grows four or five feet high; but it is not so succulent as the common sort. It might, perhaps, by cultivation and early cutting, become a useful early fodder, and it may be worth while to make some experiments with it. There are several species of tares which grow wild in bushes and hedges; but they have never been cultivated in the fields, perhaps from the difficulty in collecting the seeds, which shed as soon as they are ripe. Of these, the *Vicia cracca* appears most deserving of attention. It bears its blue flower on stems or spikes longer than the leaves, which are downy. It is very common in France among wheat; and, although a decided weed there, it is not much dreaded by the peasants, as it improves the fodder greatly. It has the appearance of great luxuriance in its growth, where it meets with a proper support. If it were mixed with some plants with a strong stem, such as the Bokhara clover (Melitotus arborea altissima), which itself affords much fodder, it might probably be cultivated to great advantage.

In the south of France there is a white perennial vetch or tare, called *Vicia pisiformis*, which is cultivated for its white seeds, of which soups are made, as with the pea and lentil. It grows in very light soils; and, although indigenous to a southern climate, it is said not to be impatient of frost. It has been called by some the Canadian lentil, or the white tare.

We shall only notice one more of the wild tares, which is an annual; it is called the yellow tare (*Vicia lutea*). It grows in stony soils and among bushes, is very branching, and rises from one to two feet high. From some experiments made by the Agricultural Society of Versailles several years ago, it would appear that this tare might be cultivated with great advantage, and is even superior to the common sort, because it can be cut two or three times during the summer, and affords a very good pasture in winter, which does not stop its vegetation: it will even bloom in a mild winter. Although short, it is so thick upon the ground, that its first cut is as heavy as that of the common tare, which is seldom worth cutting a second time.

Tares should be sown on land which is well pulverised. If after wheat, the stubble should be ploughed in with a deep furrow after a powerful scarifier has gone over the land several times to loosen it: five or six cart-loads of good farm-yard dung should be ploughed in. The tares should be drilled or dibbled, and the surface well harrowed. The intervals should be hoed early in spring: this will accelerate the growth, and insure a complete covering of the ground. As soon as the tares show the flower, they may be cut daily till the pods are fully formed; after this, any which remain uncut should be made into hay or given to sheep; for if the seeds are allowed to swell, the ground will be much exhausted. Another piece should be ready to cut by this time, and thus there may be a succession of tares and broad clover from May to November. Tares may be sown as late as August, on a barley or rye stubble, for sheep-feed early in winter, or to be ploughed in to rot in the ground where beans or peas are intended to be sown early in spring: this is perhaps the cheapest mode of manuring the land, the only expense being the seed; for the tillage is necessary at all events. In light soils, tares and buckwheat sown together immediately after barley or rye harvest, will produce a considerable crop of vegetable matter, which may be ploughed in in November. In favourable seasons, wheat may be sown immediately after, without fearing the effect of two white crops following each other; for the tares and buckwheat intervening, by their shade, and the two ploughings of the ground, one when they are sown, and the second when they are ploughed in, will entirely destroy all weeds, and give to the soil that improvement which will enable it to bear as good a crop of wheat as it would have done had it been sown the year after on a clover ley. Clover, which could not be sown with the barley, from the foul state of the land, may be sown among the wheat in the next spring, when it is hoed for the

second time. This is held out as a hint to show how an accidental interruption in a rotation may be remedied without any loss of crop or great deviation. As no rule is without exception, so no rotation can always be strictly adhered to; and those crops which admit of being sown at different times of the year are of the greatest use as substitutes for others which could not be conveniently sown without materially altering the succession of crops. In the common course of cultivation of heavy soils, where occasional fallows are necessary to clean the land, one-half of the land which requires fallowing may be sown with tares; and thus the clean unproductive summer fallow will only return at every second rotation. If the tares have been manured, or if they are fed off with sheep folded upon the land, the wheat or other crop which is sown after them will be as good as on a clean fallow, or after a good crop of clover. This alone would make tares a valuable crop; and they may be compared in their effect on heavy lands to turnips on lighter soils.

The seeds of the tare are occasionally ground into meal and made into bread. It is a very poor food; and when there is more seed than can be profitably disposed of, it may be given to pigs: but poultry, especially pigeons, are very fond of it. When given to horses, the seeds of tares are found very heating; and although they produce a fine glossy coat, they are not to be recommended for this purpose.

TARENTUM. [TARANTO.]

TARGUMS, or CHALDEE PARAPHRASES OF THE OLD TESTAMENT. During the Babylonish captivity, the language of the Jews was affected by the Chaldee dialect spoken at Babylon, to such an extent, that upon their return they could not understand the pure Hebrew of their sacred books; and therefore, when Ezra and the Levites read the law to the people, they found themselves obliged to add an explanation of it, undoubtedly in Chaldee. (*Nehem.*, viii. 8.) [HEBREW LANGUAGE; ARAMAEAN LANGUAGE.] In course of time such explanations were committed to writing, and from their being not simple versions, but explanatory paraphrases, they were called by the Chaldee word *Targum* (תרגום), which signifies 'an explanation.'

There are ten Targums extant:—1. *The Targum of Onkelos*, on the Pentateuch, is the most antient. Onkelos is supposed to have lived at Babylon. The Babylonish Talmud makes him a contemporary of Gamaliel, at the very beginning of the Christian æra. No critics place him lower than the second century. His language approaches nearer than that of the other Targums to the pure Chaldee of the books of Daniel and Ezra. He follows the Hebrew text so closely, that his work is less a paraphrase than a version, and he is free from the fables which prevailed among the later Jews.

2. *The Targum of Jonathan Ben Uzziel*, on the Prophets, is by many ascribed to an author contemporary with Onkelos, or even a little older, namely, Jonathan the son of Uzziel, a disciple of the elder Hillel. The mention of his name in the Talmuds proves him to have lived earlier than the fourth and fifth centuries. But Jahn points out certain internal marks, from which he concludes that this Targum was compiled, towards the end of the third century after Christ, from other paraphrases, some of which at least were considerably older. The Jews make Jonathan contemporary with the prophets Malachi, Zecharinh, and Haggai, and relate marvellous stories respecting the composition of his Talmud.

This Targum is more paraphrastic than that of Onkelos; its dialect is not so pure; the version is not so accurate, and indeed varies in accuracy in different parts; but it is free from the fabulous stories of the later Talmuds. It comprises the Prophets, in the Jewish sense of the word, namely, the books of Joshua, Judges, Samuel, Kings, Isaiah, Jeremiah, Ezekiel, and the twelve minor Prophets.

3. *The Targum of the pseudo-Jonathan*, on the Pentateuch, is so called from its having been erroneously ascribed to Jonathan Ben Uzziel. In purity of dialect, in its general style, and in its mode of exposition, it is far inferior to the Targum of Jonathan. It abounds in silly fables, and displays great ignorance of Hebrew on the part of its author. From internal evidence, such as its mention of the Turks and Lombards, it is evident that it could not have been written earlier than the seventh, or perhaps the eighth, century.

4. *The Jerusalem Targum*, on the Pentateuch, of which however it omits large portions, and sometimes explains only single words, is evidently later than that of the pseudo-Jonathan, which it generally follows closely, occasionally departing from it for the worse. Its dialect is very impure, abounding in Greek, Latin, and Persian words.

The other Targums scarcely deserve a separate notice. An account of them, and lists of the editions and Latin versions of the Targums, will be found in the works quoted at the end of this article. Taken together, the Targums form a paraphrase of the whole of the Old Testament, except the books of Daniel, Ezra, and Nehemiah, which called the less for such an exposition, as they are to a great extent written in Chaldee.

(Prideaux's *Connection*, pt. ii., bk. viii.; the 'Introductions' of Horne and Jahn.)

TARI'FA, a small sea-port town situated in the narrowest part of the Strait of Gibraltar, on a point of land projecting into the sea; in 36° 3′ N. lat. and 5° 36′ W. long. The Arabs called it Jezirah Tarif (the Island of Tarif), because a Berber, named Tarif Ibn Malek Al-ma'feri, who was the lieutenant of Músa Ibn Nosseyr, landed on the little island facing the port with a small force, two years before the final conquest of Spain by the Arabs. [MOORS.] Tarifa is now a dependency of Cadiz, which has been made of late the capital of a province of the same name. In 1295 it was besieged by the Africans under Abú Yúsuf, but it was stoutly defended by Don Alonso Perez de Guzman 'el Bueno,' the progenitor of the dukes of Medina Sidonia, who would not surrender that fortress to them, notwithstanding they threatened to behead his only son, which they did before his eyes. In 1340 a great battle was fought near Tarifa, between Alphonso XI. of Castile and Abú-l-hasan, sultan of Fez and Morocco, when the former was victorious.

TARIFF, a table of duties to be paid on goods imported or exported. The principle of a tariff depends upon the commercial policy of the body by which it is framed, and the details are constantly fluctuating with the change of interests and the wants of the community, or in pursuance of commercial treaties with other states. The British tariff has undergone six important alterations within the last sixty years, namely in 1787, in 1809, 1819, 1825, 1833, and 1842. The act embodying the tariff of 1833 is the 3 & 4 Wm. IV., c. 56. Its character has been described in the Report of a Committee of the House of Commons in 1840, on the Import Duties, as presenting 'neither congruity nor unity of purpose: no general principles seem to have been applied. The tariff often aims at incompatible ends: the duties are sometimes meant to be both productive of revenue and for protective objects, which are frequently inconsistent with each other. Hence they sometimes operate to the complete exclusion of foreign produce, and in so far no revenue can of course be received; and sometimes, when the duty is inordinately high, the amount of revenue becomes in consequence trifling. An attempt is made to protect a great variety of particular interests at the expense of the revenue and of the commercial intercourse with other countries.' The schedules to the act 3 & 4 Wm. IV., c. 56, contain a list of 1150 articles, to each of which a specific duty is affixed. The unenumerated articles are admitted at an *ad valorem* duty of 5 and of 20 per cent, the rate having previously been 20 and 50 per cent. In 1838-9, seventeen articles produced 94¼ per cent. of the total customs' duties, and the remainder only 5¾ per cent., including twenty-nine, which produced 3⅝ per cent. The following table of the tariff of 1833, showing the duties received in 1838-9, is an analysis of one prepared by the inspector-general of imports for the parliamentary committee to which allusion has been made:—

	No. of Articles.	£
1. Articles producing on an average less than 24*l.*	349	8,050
2. Ditto less than 240*l.*	132	31,629
3. Ditto less than 713*l.*	45	32,056
4. Ditto less than 2,290*l.*	107	244,933
5. Ditto less than 22,180*l.*	63	1,397,324
6. Ditto less than 183,864*l.*	10	1,838,630
7. Ditto less than 2,063,885	9	18,575,071
8. Articles on which no duty has been received	147	Excess of drawback 5,398
	862	22,122,095

The new tariff, which is on the point of becoming law, contains very numerous alterations. Cattle and fresh meat are admitted, for the first time, on payment of duty; and the reduction of duty on salt-meat is considerable. Time will be required to show the result of the various changes which it contains. The heads of the tariff are comprised under nineteen heads, and the articles enumerated are as many as those in the tariff of 1833.

TARIK. [Roderic.]

TARLTON, RICHARD, a comic actor of great celebrity in the reign of Queen Elizabeth, was born in the hundred of Condover, in Shropshire. The date of his birth is not known. He died in 1588, and was buried (September 3) at St. Leonard's, Shoreditch, London.

Tarlton was especially distinguished for his performance of the clowns of the old English drama, in which he is spoken of as having been unrivalled, and seems besides to have been one of those clowns who spoke 'more than was set down for them:' he was famous for his extempore wit, which indeed must have been an important addition to the dull and vulgar speeches generally assigned to the clowns before Shakspere's time—he interlarded with his wit the lean and hungry prose. Dr. Cave, 'De Politica,' Oxford, 4to., 1588, says (we translate Cave's Latin), 'We English have our Tarlton, in whose voice and countenance dwells every kind of comic expression, and whose eccentric brain is filled with humorous and witty conceptions.'

Stow mentions that Tarlton was one of the twelve actors whom Queen Elizabeth, in 1583, constituted grooms of the chamber at Barn Elms: he seems indeed to have been one of her especial favourites; for Fuller says, that 'when Queen Elizabeth was serious (I dare not say sullen), and out of good humour, he could undumpish her at his pleasure. Her highest favourites would, in some cases, go to Tarlton before they would go to the queen, and he was their usher to prepare their advantageous access to her.'

One of Tarlton's last performances was in 'The Famous Victories of Henry V.;' this was in 1588, at the Bull in Bishopsgate Street, to which theatre he seems to have been generally attached. Of this play, which is a much earlier one than Shakspere's 'Henry V.,' a full account is given in the introductory notice to 'Henry VI., Parts I. and II.,' in Knight's 'Pictorial Shakspere.' It is one of the 'Six Old Plays,' printed by Nichols in 1779.

Tarlton is known to have written at least one play, 'The Seven Deadly Sins,' which, though never printed, and now lost, was much admired. Gabriel Hervey, in his 'Four Letters and certaine Sonnets especially touching Robert Greene and other Parties by him abused,' 4to., 1792, speaks of a work written by Thomas Nashe, 'right formally conveyed according to the stile and tenour of Tarlton's president, his famous playe of 'The Seven Deadly Sinnes,' which he designates as a 'most deadly but most lively playe.'

There is a portrait of Tarlton, in his clown's dress, with his pipe and tabor, in the Harl. MS. 3885; and a similar portrait of him (probably the one is a copy of the other) in the title-page of a pamphlet called 'Tarlton's Jests,' 4to., 1611. A copy of the former portrait is given in Knight's 'Shakspere,' at the end of 'Twelfth Night.' The peculiar flatness of his nose is said to have been occasioned by an injury which that feature received in parting some dogs and bears.

(Baker's *Biographia Dramatica*, by Reed and Jones.)

TARN, a river in France, belonging to the system of the Garonne. It rises near Mount Lozère, one of the Cévennes, in the department of Lozère, and flows first west to Sainte Enimie in the same department, 27 miles, and then south-west 27 miles to Milhau, in the department of Aveyron; from thence west-south-west 88 miles, by Alby and Gaillac, department of Tarn, to St. Sulpice; and from thence 48 miles north-west and west by Montauban (department of Tarn and Garonne) into the Garonne, below Moissac. The navigation is marked in Brué's map of France as commencing at Gaillac, and has a length of about 60 miles; other authorities make the navigation commence at Alby, and this statement agrees with the official accounts, which assign to the river a navigation of 90 miles. It has several tributaries, but none of them are navigable. [France; Garonne; Tarn (department); Tarn et Garonne.]

TARN, a department in the south of France, bounded on the north and north-east by that of Aveyron, on the south-east by that of Hérault, on the south by that of Aude, on the south-west and west by that of Haute Garonne, and on the north-west by that of Tarn and Garonne. The form approximates to that of a parallelogram, having its sides respectively facing the north-east, south-east, south-west, and north-west. The extreme length, from north-west to south-east, from the neighbourhood of Penne on the Aveyron to the border of the department of Hérault, near St. Pons, is 65 miles; the extreme breadth, from the neighbourhood of Valence to that of Puy-Laurens, is 46 miles. The area is estimated at 2222 square miles, which is somewhat under the average area of the French departments, and rather greater than the conjoint areas of the two English counties Surrey and Sussex. The population, in 1826, was 327,655; in 1831, 335,844; and in 1836, 346,614, showing an increase in five years of 10,770 persons, or above 3 per cent., and giving 156 inhabitants to a square mile. In amount and density of population it is below the average of the French departments, and is very far below the county of Surrey alone in amount, and in density of population below both Surrey and Sussex. Alby, the capital, is on the Tarn, 339 miles in a straight line nearly due south of Paris, or 482 miles through Orléans, Châteauroux, Limoges, Cahors, Montauban, and Toulouse; a very circuitous route, but the only one laid down in Reichard's Road-book.

The department is very mountainous in the south-east part, where it comprehends a portion of the Cévennes. A range of hills branching off from this chain, and running nearly parallel to it, crosses the north-west part of the department, skirting the valley of the Tarn; and there are some other ranges of less elevation and importance. The peak of the Cévennes, which overlooks the town of Sorèze, in the south of the department, has an elevation of 1760 feet. The eastern side of the department, bounded by a line drawn southward or south by east from the junction of the Viaur and the Aveyron, is chiefly occupied by the granitic or other primary or by the earlier secondary formations: west of this boundary-line the tertiary formations prevail; only on the banks of the Cerou and the Aveyron in the northern part, and about Puy-Laurens in the southern part of the department, the secondary formations, which lie between the cretaceous group and the new red-sandstone group, crop out from beneath the tertiary rocks. The mineral productions are of no great importance. There was, in 1834, only one coal mine worked; it gave employment to 273 workmen within the mines and 42 others, making a total of 315: the quantity of coal produced was 19,933 tons, and the total value 13,152*l.*, or 13*s.* 9*d.* per ton on the average. The quantity produced in 1835 was 18,420 tons. There were, in 1834, two iron-works with three forges for the manufacture of wrought-iron: the ore was converted directly into malleable iron, and charcoal was the only fuel employed. Lead and copper ore are said to be found, but no mines are now worked. There are marble-quarries, plaster-pits, and pits for porcelain and potters' clay.

The department belongs entirely to the basin of the Garonne. The Tarn, one of the principal feeders of that river, touches the border of the department just above the junction of the little river Rance, and flows along the border till that stream (which belongs altogether to the department of Aveyron) joins it; it then quits the border and flows westward to Alby and then south-west to the junction of the Agout, shortly after which it quits the department to enter that of Haute Garonne: the navigation commences at Gaillac, or, according to some authorities, at Alby. Just above Alby the Tarn has a fall, or rather a series of falls, over the steep face of a limestone rock, in which it has worn a number of channels, which so divide the stream, that when the water is low it may be crossed by leaping from one prominence to another: this fall is called Saut du Sabot or Saut du Tarn. The tributaries of the Tarn which belong to this department are the Aveyron, the Tescou, and the Agout. The Aveyron has only a small part of its course in this department, and another small part along the border; its affluent the Viaur has part of its course along the border; but the Cerou and the Verre, two other affluents of the Aveyron, belong to this department almost entirely. The Agout rises in the department of Hérault, but belongs almost entirely to this department,

as do its affluents, the Viau (which receives the Vebre), the Gijou (which receives the Gijas and the Berlou), the Tauré (which receives the Lam and the Lamette), the Sor, the Bagas, and the Adou. None of the tributaries of the Tarn or their affluents are navigable, though some of them are of considerable length, the Aveyron being above 120 miles, the Viaur 60, the Agout 75, and the Adou 45; the others are smaller.

There are in the department five Routes Royales, or government roads, which had, January 1, 1837, an aggregate length of 207 miles, of which 116 miles were in good repair, 85 miles out of repair, and 6 miles unfinished. None of these roads are of the first class: the principal are those which lead from Alby south-west, by Gaillac, Lisle, and Rabastens, to Toulouse; south, by Réalmont and Castres, across the Cévennes into Languedoc; east by Villefranche to La Cavalerie, on the high road from Paris to Montpellier; and north-east by Carmeaux to Rodez, in the department of Aveyron. Roads branch from the Alby and Toulouse road at Gaillac, and lead, one west to Montauban and Bordeaux, one north by Cahusac and Cordes to Autillac, in the department of Cantal. Another road leads from Castres by Lavaur to Toulouse. The departmental roads had at the same time an aggregate length of 485 miles, of which 296 were in repair and 189 out of repair. The vicinal roads had an estimated aggregate length of 7500 miles in round numbers.

The area of the department is equal to rather more than 1,400,000 acres; considerably more than one-half of this is under the plough. The soil, except in the mountainous parts, is generally fertile; but agriculture is in a very backward state; manures are neglected, and the system of rotation is very faulty. These deficiencies are chiefly observable in the arrondissements of Alby and Gaillac, which comprehend the beautiful valley of the Tarn; in the arrondissements of Castres and Lavaur, in the south of the department, improvements have been more readily adopted. The produce in grain, comprehending wheat, barley, oats, rye, maize, and buckwheat, is sufficient to supply the consumption of the department and to leave a little for exportation. Pulse, flax, hemp, woad, aniseed, coriander, and saffron are also raised; the growth of woad is of long establishment and considerable importance. The meadow and grass lands may be estimated at about 100,000 acres, and the heaths, commons, and other open pastures at 150,000 acres. The valleys and the slopes of the hills afford good pasturage, and the breeding of cattle is one of the principal sources of the wealth of the department. Sheep and pigs are numerous, and the veal is in high repute. The breed of horses is improving. The vineyards occupy nearly 80,000 acres; the cultivation of the vine is very skilfully and carefully managed. The red wines of Cunac, Caisaguet, St. Juéry, St. Amarans, and Gaillac are of the first class; those of Meilhart, La Roque, Florentin, La Grave, Tecon, and Rabastens are of the second class: Gaillac produces some white wines. The average produce of the vintage is estimated at above 430,000 hectolitres, valued at 5,500,000 francs. The orchards and gardens occupy about 6000 acres. The olive is not cultivated to any extent.

The woodlands occupy 200,000 acres; the oak, the beech, the ash, the maple, the chestnut, the walnut, the mulberry, and the wild cherry-tree are common.

Bees are numerous, but the breeding of the silkworm is not carried on to the extent of which it is capable. The wild boar, the roebuck, the wolf, the fox, the badger, the polecat, and the hedgehog are found; and small game is tolerably abundant.

The department is divided into four arrondissements, as follows:—

Name.	Position.	Area in Square Miles.	Population. 1831.	Population. 1836.	Communes.	Cantons.
Alby	N.E.	553	80,954	84,929	96	8
Castres	S. and E.	861	131,154	136,188	95	14
Gaillac	N.W.	496	71,323	72,001	79	8
Lavaur	S.W.	312	52,413	53,496	57	5
		2,222	335,844	346,614	327	35

In the arrondissement of Alby are—Alby, or Albi on the Tarn; population, in 1831, 9049 for the town, or 11,665 for the whole commune; in 1836, 11,801 for the commune [ALBY]; Castelnau and Lescure, on the Tarn; Réalmont (pop. 2100 for the town, or 2660 for the whole commune) on the Adou, and Villefranche and Denat on a tributary of that river; Valence, Carmeaux, Monestiés, and Salles, on the Cerou, or its tributaries; Villeneuve, on the Verre: and Pampellonne, on the Viaur. Castelnau, distinguished as Castelnau-de-Bonnafoux, is built on a slope rising from the north bank of the Tarn, just below Alby, and is commanded by an old castle. Lescure was anciently fortified; it is a little above Alby. Réalmont has a Protestant church, and is a tolerably well-built town: there are some linen manufactories and a bleach-green; serge and cotton and worsted hose are also made: eight fairs are held in the town. Villefranche has nine considerable cattle-fairs. Valence is regularly laid out with straight streets, in a well-wooded district, from which a considerable quantity of timber is sent to Alby, Gaillac, and Bordeaux: the town has five large fairs, chiefly for cattle. Leather and glass are made at Carmeaux; and considerable trade is carried on at Monestiés in linen, thread, and cattle. Monestiés has thirteen fairs, Salles two, and Villeneuve (distinguished as Villeneuve-sur-Verre) five. Pampellone, or Pampelonne, is surrounded by the remains of its fortifications, and has two gates. There are two principal streets, and two large places or squares. Considerable business is done in horsecloths, which are manufactured; and there are six yearly fairs.

In the arrondissement of Castres are—Castres, on the Agout, population, in 1831, 12,032 for the town, or 16,418 for the whole commune; in 1836, 17,602 for the whole commune [CASTRES]; Brassac, Fort-de-Ferrières, Roquecourbe, Burlats, and Vielmeur, all on the Agout; Angles, Hautpoul, Mazamet (pop. 3896 for the town, or 7098 for the whole commune), and La Brugière, on the Tamé or its tributaries; La Caune (pop. 1650 for the town, or 3681 for the whole commune), on the Gigas; Vabres, on the Gijou; Mondragon, on the Adou; La Bessonié and Lautrec, between the Adou and the Agout; and Dourgne and Sorèze (pop. 1574 for the town, or 2817 for the whole commune), in the southern corner of the department. Brassac, distinguished as Brassac-de-Belfourtes, is the centre of a considerable manufacture of dimity and other cotton goods, carried on in the village of Brassac-Castelnau (which is included in the commune of the town), and other villages around. Fort de Ferrières takes its name from an antient fort, once used as a state prison, now as a manufactory of cotton goods. Roquecourbe, situated in a fertile district, has a Protestant church, and is the seat of a considerable manufacture of woollen stockings; it has four yearly fairs. Vielmeur, or Vielmur, has a manufacture of cotton yarn and of knitted stockings; it has five fairs. Angles has manufactures of woollen and cotton yarn, and woollen and cotton goods. Hautpoul has an antient castle, formerly the capital of the barony of Hautpoulois: it was stormed, A.D. 1212, by Simon de Montfort. Mazamet is a busy town; it has a number of manufactories for woollen goods of various sorts, some dye-houses, and several paper-mills; it has four fairs for cattle, wool, and manufactured goods. Flannels, blankets, and other woollens are manufactured at La Brugière, distinguished as La Brugière-Dulac; hosiery and dimity at La Caune; and calicoes, dimities, and other cotton goods, and flannel at Vabres, distinguished as Vabres-des-Sénégats. Vabres has a Protestant church: four fairs are held in the year. Mondragon, now of little importance, was formerly of considerable note: it has six yearly fairs; a number of pigs are sold here. Lautrec is on a small eminence, and has the ruins of an antient castle; it has ten yearly fairs. The neighbourhood produces good wine and melons. Lautrec was formerly a viscounty: it was held in the time of François I., by Odon de Foix, a general of considerable distinction in the Italian wars of that king. Dourgne has some manufactures of coarse woollens, three cattle-fairs, and in the environs some important quarries of white and gray marble. Sorèze had formerly a Benedictine abbey, where twelve young persons of noble family, but without fortune, received a gratuitous education: it has now a college or high school, one of the most important in the south of France. Cotton yarn, woollen and cotton hosiery, and leather are made: and there are two yearly fairs. Sorèze was fortified by the Huguenots in the religious wars of the sixteenth century, but the ramparts

were destroyed in the reign of Louis XIV. At La Roquette, near Castres, are two remarkable natural curiosities: Le Rocher tremblant, a mass of stone, comprehending about 360 cubic feet, and resting on a very narrow base, so as to rock or vibrate sensibly when pushed, like the Logan or Logging Stone, in Cornwall; and the grotto which bears the name of St. Dominic, from having served as a retreat to that celebrated ecclesiastic.

In the arrondissement of Gaillac are—Gaillac (population in 1831, 5552 for the town, or 7725 for the whole commune; in 1836, 8199 for the commune), on the Tarn; Lisle (pop. 1726 for the town, or 5065 for the whole commune) and Rabastens (pop. 3417 for the town, or 6966 for the whole commune), on the same river; Penne, on the Aveyron; Cordes (pop. 2239 for the town, or 2602 for the commune), on the Cerou; Cestayrols, Cahuzac, Castelnau de Montmirail, and Puiceley, on or near the Verre; Salvaignac, near the Tescou; and Cadalen, between the Tarn and the Adou. Gaillac is on the right or north bank of the Tarn; it is an old town without any striking public building; there are an hospital and a small theatre. East of the town is a suburb, well laid out and pleasantly situated. There are brandy distilleries and cooperages, and one or two tan-yards, dye-houses, and yards for building boats and other river-craft. Trade is carried on in corn, wine, and vegetables: there are seven yearly fairs. Lisle (otherwise L'Ile d'Alby), on the right bank of the Tarn, is a small town, with a place or square regularly laid out and adorned with a fountain. Considerable trade is carried on in corn and wine, and there are seven yearly fairs for cattle, linen cloth, and wool. Rabastens, in a fertile plain on the right bank of the Tarn, is an ill laid out and ill-built town. There is a pleasant suburb, and adjacent to it an agreeable promenade. Some blankets are manufactured, and some trade carried on in corn, wine, and fruit: there are six yearly fairs. Rabastens has the ruins of an antient castle, which was taken by Simon de Montfort in the religious wars of the thirteenth century, and by the English in the wars of the fourteenth century. Cordes is on an elevated site on the left bank of the Cerou: it has a handsome place or square, and the ruins of an antient castle: linen and leather are manufactured; there is a considerable weekly market for corn and fruit, and there are six yearly fairs. Castelnau de Montmirail was antiently a place of strength: it is in a district fertile in corn and fruit. Coarse marble is quarried in the neighbourhood. Puiceley is on a height on the right bank of the Verre, not far from Castelnau de Montmirail; the chief business of the town is the manufacture of casks, joiners' and other wood work, and cheeses of great delicacy: there are four yearly fairs. Abundance of wood is obtained in the adjacent forest of Grésine. Salvaignac, or Salvagnac, is pleasantly situated on an eminence not far from the left bank of the Tescou: it has some iron-forges, and considerable trade is carried on in cattle: there are six yearly fairs. Some trade in cattle is carried on at Cadalen.

In the arrondissement of Lavaur are—Lavaur or Laveur, near the Agout (population in 1831, 4422 for the town, or 7179 for the whole commune; in 1836, 7205 for the commune), Giroussens and St. Sulpice, on or near the same river; Puy-Laurens (population 1799 for the town, or 6160 for the whole commune), near the head of the Giron, an unimportant feeder of the Garonne; and Graulhet (population 2458 for the town, or 5097 for the whole commune) and Briatexte, on or near the Adou. Lavaur is on the left bank of the Agout, which is here crossed by a modern bridge of bold construction. The town was defended by walls and protected by a castle in the eleventh century. In the religious wars which signalised the early part of the thirteenth century, it was one of the strongholds of the Albigenses, from whom it was taken, A.D. 1211, by Simon de Montfort, who committed the most fearful cruelties. The place is divided into the old town and the new town, but is altogether ill built. The chief branch of industry is silk-throwing. The raw silks of Haut or Upper Languedoc are brought here; and when thrown are sent to Nîmes and Lyon. Some silk-stuffs for the upholsterers, and silk-stockings are made; and there are dye-houses and tan-yards: there are three yearly fairs. Lavaur has a high school, a small public library, an agricultural society, and a subordinate court of justice. Giroussens was formerly a place of strength, and the object of contest in the English wars of the fourteenth century. It stands on the right bank of the Agout: the townsmen manufacture brown pottery, but their ware is less in request than formerly. There is one yearly cattle-fair. Puy-Laurens is on a small eminence commanding the surrounding fertile plain. It was one of the strongholds of the Huguenots in the religious wars of the sixteenth century: but the fortifications were rased in the reign of Louis XIII. The town appears to have been after this still occupied by the Protestants, who had here an Academy of Sciences, which was suppressed after the revocation of the Edict of Nantes. Silk-throwing is carried on, and there is considerable trade with Spain in horses and mules: there are five well-attended yearly fairs. Graulhet, on the left bank of the Adou, has a considerable manufacture of hats and woollen stuffs, and a number of tan-yards. Considerable trade in horses is carried on, and there are five cattle-fairs. The district round the town is fertile: millstones are dug.

The population, when not otherwise described, is from the census of 1831.

That part of France which now constitutes this department was chiefly comprehended, in the earliest historical period, in the territory of the Ruteni. The southern portions were comprehended in the territory of the Umbranici, and the south-western in that of the Tolosates. That part of the territory of the Ruteni which was comprehended in the department is considered by D'Anville to have been occupied by the Ruteni Provinciales, distinguished by Cæsar by that epithet from the other Ruteni, as being within the limits of the Roman province at the time of his command in Gaul. The Umbranici and Tolosates were also within the province. The Ruteni were defeated by Fabius Maximus, B.C. 121, and it was probably at this time that part of them (the Ruteni Provinciales) became subject to Rome. The independent Ruteni took an active part in the general revolt of the Gauls under Vercingetorix, near the close of Cæsar's command, and were sent by Vercingetorix to ravage the lands of the Volcae Arecomici, who were Roman provincials. They were subdued by Cæsar. All these nations appear to have belonged to the great Celtic stock. Under the Romans the Ruteni (including the Ruteni Provinciales) appear to have been comprehended in the province of Aquitania Prima; the Umbranici and Tolosates, in Narbonensis Prima. The town of the Albienses (*Civitas Albiensium*) of the 'Notitia' was probably Alby: the Albigi of the anonymous Geographer of Ravenna was probably the same place. No other Roman town can be identified with any locality within the department. The river Tarn is noticed by Ausonius (*Mosellæ Descriptio*, 465) and Sidonius Apollinaris (*Carmen*, xxiv. 45) under the name of Tarnis: the former bestows on it the epithet 'aurifer,' 'the gold-bearing;' the second calls it 'citus,' the 'swift.'

In the middle ages, and down to the period of the Revolution, the larger portion of this department was known as the territory of L'Albigeois; the arrondissement of Lavaur, and the adjacent parts, formed the district of Le Bas (Lower) Lauraguais: both these were comprehended in Le Haut (Upper) Languedoc. Alby was the chief town of L'Albigeois; Lavaur of Bas Lauraguais.

Upon the downfal of the Roman Empire this part of France passed into the hands of the Visigoths, and subsequently of the Franks under Clovis. The district of L'Albigeois was part of the great duchy of Guienne in the time of the later kings of the Merovingian dynasty. It was subsequently held in succession by the counts of Toulouse, the viscounts of Béziers, and the counts of Carcassonne: and was, in the early part of the thirteenth century, the scene of the fearful cruelties perpetrated in the crusade against the Albigeois or Albigenses, a sect deriving their name from the district, and persecuted by the Romish church as heretical. [ALBIGENSES.] In the sequel of this crusade the district of L'Albigeois was annexed to the crown. The district of Lauraguais was successively held by the counts of Carcassonne and Barcelona; one of these latter, having become king of Aragon, ceded Le Lauraguais to the Viscount of Béziers, who again ceded it to St. Louis, king of France. It was alienated by Louis XI., who gave it to the counts of Auvergne, but was reunited to the crown by Henri IV.

TARN ET GARONNE, a department in the south of France, situated between 43° 47′ and 44° 23′ N. lat., and 0° 40′ and 2° 0′ E. long. It is bounded on the north by the department of Lot, on the north-east by that of Avey-

ron, on the east and south-east by that of Tarn, on the south by that of Haute Garonne, on the south-west by that of Gers, and on the north-west by that of Lot et Garonne. Its form is irregular; the greatest length is from north-east to south-west, from the border of the department of Aveyron near Parisot, to the bank of the little river Larax, near Lavit-de-Lomagne, 64 miles; the greatest breadth at right angles to the length, is from the border of the department of Lot et Garonne, near Montaigut, to the border of the department of Haute Garonne, near Grizalles, 44 miles. The area of the department is estimated at 1421 square miles, which is not so much as two-thirds of the average area of the French departments, and is rather less than the area of the English county of Sussex. The population, in 1826, was 241,586; in 1831, 242,509; and in 1836, 242,184, showing a very trifling increase (598 persons, less than 0·25 per cent.) in the ten years from 1826 to 1836; and in the latter half of the term a positive decrease. The number of inhabitants to a square mile, in 1836, was 170, which is rather above the average density of the population of France; but the department is inferior in amount of population to most other departments; and both in amount and density of population to the English county with which we have compared it. Montauban, the capital, is 335 miles in a direct line south by west of Paris, or 408 miles by the road through Paris, Orléans, Châteauroux, Limoges, and Cahors.

This department was not one of those formed at the first establishment of the departmental division of France by the National Assembly, A.D. 1790; but was created by a senatus-consultum under the reign of Napoleon, A.D. 1808. It was formed from the arrondissement of Montauban, taken from the department of Lot; the arrondissement of Castel Sarrasin, taken from the department of Haute Garonne; the cantons of Auvillard, Montaigut, and Valence, taken from the arrondissement of Agen, in the department of Lot et Garonne; the canton of Lavit-de-Lomagne, taken from the arrondissement of Lectoure, in the department of Gers; and the canton of St. Antonin, taken from the arrondissement of Villefranche, in the department of Aveyron. The department thus formed was divided into three new arrondissements, Montauban, Moissac, and Castel Sarrasin.

The department has no mountains and scarcely any hills; slight undulations alone vary its surface. The greater part is occupied by the tertiary formations of the basin of the Gironde: the part north-east of St. Antonin, on the Aveyron, and Puy-la-Roque, is occupied by the secondary formations which intervene between the chalk and the red marl or new red sandstone. Some of our authorities enumerate coal among the productions of the department; but this is hardly consistent with its geological character, nor were any coal-mines wrought in 1834 and 1835, of which the official returns are before us. Some iron is obtained; and there was, in 1834, one iron-work, with two furnaces for making pig-iron, and five forges for making wrought-iron. Charcoal was the fuel almost exclusively employed. Marble and good freestone are quarried in the north-east parts of the department; and limestone, marl, and potters'-clay are dug in several places.

The department belongs altogether to the basin of the Garonne. The Garonne itself enters it on the south side, a little below Grenade, and flows north-west by Verdun and Le-Mas-Garnier, to the junction of the Tarn: it then flows a few miles west by Auvillard; and turning again north-west, and passing Valence, quits the department. It has about 40 miles of its course (49 miles, according to the official account) in this department, navigable throughout. The Tarn enters the department on the south-east: it flows first north-west by Montauban to the neighbourhood of La Française; and then, in a winding channel, westward into the Garonne, which it joins on the right bank: its whole course in this department may be estimated at 36 miles (40 according to the official account), navigable throughout. These are the only navigable rivers. Of smaller streams, the Garonne receives on the left bank the Lambon, the Gimone, and the Serre, above the junction of the Tarn; and the Larax, or Rats, below the junction of that river. The Barguelone (formed by the junction of the Grande Barguelone and the Petite Barguelone) and the Saône (which receives the Seune) join the Garonne on the right bank, below the junction of the Tarn, and beyond the limits of the department, to which however a considerable part of their course belongs. The Aveyron, a considerable feeder of the Tarn, which it joins on the right bank, between Montauban and La Française, has the lower part of its course in this department or along the boundary. The Tarn receives also the Tescou (of which the Tesconnet is a feeder) and the Lemboulas (of which the Latté is a feeder), both on the right bank. The Aveyron receives the Seye, the Bonnette, and the Lere, on the right bank; and the Verre and the Tause on the left bank.

The department had, 1 Jan., 1837, seven Routes Royales, or government roads, with an aggregate length of 158 miles, viz. 150 miles in good repair and 8 miles unfinished: the aggregate length of the departmental roads at the same time was 234 miles, viz. 156 miles in good repair and 78 miles unfinished: the bye-roads and lanes had an aggregate length of above 4200 miles. The principal road is that from Paris to Montauban and Toulouse: it enters the department on the north side, at the village of La Madeleine, and runs southward by Caussade and Réalville to Montauban; and from thence, still southward, by Grizalles, a little beyond which it quits the department, to Toulouse. A road from Montauban runs west-north-west, parallel to the course first of the Tarn, afterward of the Garonne, by La Française, Moissac, and Valence, to Bordeaux: another road runs south-west, by Montech and Beaumont-de-Lomagne, to Auch; and a third, east-south-east, to Gaillac and Alby, in the adjacent department of Tarn. A road which enters the department on the north-east runs by Caylus and Septfons, and, uniting with the road from Paris to Toulouse at Caussade, forms the communication between Rodez and Montauban. A road running from Moissac along the valley of the Garonne, by Castel Sarrasin, St. Porquier, Seatalen, and Fignan, to Grizalles, forms the shortest communication between Bordeaux and Toulouse.

The climate is generally mild, but subject to variations, which occasion frequent attacks of catarrh and rheumatism. The mean temperature in winter is from 36° to 39° of Fahrenheit, that of spring and autumn from 59° to 64°, and that of summer from 81° to 86°. Rains are frequent in spring: the summer heat increases gradually towards the end of July, when it is very great: autumn is the pleasantest season of the year: winter, though sometimes very cold, is generally dry. Snow rarely falls.

The area of the department may be estimated at about 910,000 acres in round numbers, of which about 575,000 acres, or above six-tenths, are under the plough. The soil is various; in some parts stiff and clayey, in others light and sandy; so sandy in some places as to be incapable of cultivation. The greater part however is very fertile: the plains and alluvial tracts which line the banks of the Garonne, the Tarn, and the Aveyron, are among the richest in France; but those along the banks of the Garonne are liable to be injured by the inundations of that river. The farms are generally separated by quick-hedges, and adorned with clumps of the wild quince-tree. The most important article of agricultural produce is wheat, which is of excellent quality. It is ground into flour, especially at Montauban; and large quantities are exported to America. Barley, oats, rye, maize, pulse, potatoes, vegetables of excellent quality, rape, flax, and hemp, are also cultivated to a considerable extent.

The meadows have an extent of about 43,000 or 44,000 acres, the heaths and open pastures of more than 41,000 acres. The number of horned cattle and sheep is not by any means so considerable as it might be: the breed of sheep has been however gradually improving, and the wool is of good quality. Horses, fitted for the light cavalry, are reared; and a considerable number of mules are bred for the Spanish market. The breeding of swine is on the increase. Poultry, especially ducks and geese, are numerous: they are salted in considerable quantity; and their livers, which sometimes weigh two pounds, are made into the pies for which this part of France, Toulouse especially, is so famous. The quills also form an important article of trade.

The vine is extensively cultivated on the slopes and more elevated plains, where the soil is commonly of a whitish colour, of mingled clay and fine sand, little adapted for the growth of corn, but suited to the vine, which succeeds admirably in the district between the Tarn and

the Garonne. The vineyards have an extent of about 90,000 acres. A large part of their produce is made into brandy for exportation. The wine is of fair quality, but not first-rate; and in general of a deep colour, which it loses by age.

The orchards and gardens occupy about 4500 acres: the walnut and chestnut trees are of great size: the white mulberry is cultivated in order to rear the silk-worm, which is an object of attention, though not so extensively as it might be made. The woods occupy about 110,000 acres. Game and fresh-water fish are abundant: great quantities of the lamprey and the shad are taken in the Garonne in the spring.

The department is divided into three arrondissements, as follows:—

Name.	Situation.	Area in Sq. miles.	Population in 1831.	Population in 1836.	Cantons.	Communes.
Montauban	E.	619	107,853	106,799	11	62
Moissac	N.W.	341	62,489	62,735	6	49
Castel-Sarrasin . .	S.W.	461	72,167	72,650	7	80
		1421	242,509	242,184	24	191

In the arrondissement of Montauban are—Montauban, on the Tarn (population, in 1831, 18,255 for the town, or 25,460 for the whole commune; in 1836, 23,865 for the commune) [MONTAUBAN]; La Française (pop. 3686), near the Tarn; Varen, St. Antonin (pop. 2861 for the town, or 5482 for the whole commune), Montricoux, Bioullé, Négrepelisse, and Réalville (pop. 3030), on or near the Aveyron; Bruniquel, on the Verre; Parisot, on the Seye; Caylus (pop. 1518 for the town, or 5319 for the whole commune), on the Bonnette; Puy-la-Roque, Septfons, Caussade (pop. 2441 for the town, or 4479 for the whole commune), on or near the Lerc or its affluents; Montpezat and Molières, on or near the Lemboulas; Mirabel, between the Lerc and the Lemboulas; and Montelar, on the Tescounet. La Française has a manufacture of pottery from the fine clay which is dug in the neighbourhood. St. Antonin is on the right bank of the Aveyron, at the junction of the Bonnette. There are manufactures of serge and other woollen stuffs, and there are tan-yards and paper-mills: considerable trade is carried on in leather and dried plums. Montricoux has twelve yearly fairs: marble is quarried near the town. Négrepelisse was formerly inhabited chiefly by the Huguenots; and when Louis XIII. besieged Montauban (A.D. 1621), he put a garrison into this town; but the inhabitants rose upon the garrison, and put them to the sword, in consequence of which the town was taken and burnt by the royal army. Cotton goods are woven, and trade is carried on in corn, wine, and hemp: there are ten yearly fairs. At Réalville considerable trade is carried on in corn and flour: there are five yearly fairs. Bruniquel has an iron-work. Caylus has eleven yearly fairs, and a trade in corn. Caussade has some manufactures of linen and woollen; and the townsmen carry on trade in corn, flour, saffron, and truffles: there are eight yearly fairs.

In the arrondissement of Moissac are—Moissac, on the right bank of the Tarn (population, in 1831, 5950 for the town, or 10,165 for the whole commune; in 1836, 10,618 for the commune) [MOISSAC]; Auvillard or Auvillar (population 1963 for the town, or 2302 for the whole commune), on the Garonne; Valence (population 1994 for the town, or 2875 for the whole commune), between the Garonne and the Barguelone; Lauzerte (population 1753 for the town, or 3685 for the whole commune) and Miramont, on the Petite Barguelone; Monjoy or Montjoye and Castel-Sagrat, on or near the Saône; Le Bourg-du-Visa, on a small feeder of the Saône; Montaigut or Montaigu (population 2000 for the town, or 4172 for the whole commune) and Roquecor, on the Seune; and Dunes, near the western border of the department. At Auvillard or Auvillar (sometimes written Auvillards) are manufactures of earthenware and worsted hose: there are four yearly fairs. The neighbourhood is productive in wine. Valence (distinguished as Valence d'Agen) has four yearly fairs: the townsmen tan leather and prepare quills for writing. Lauzerte is in a picturesque situation on a rocky eminence, at the junction of the Lendou with the Petite Barguelone: it has eleven fairs, where much business is done in corn, wine, and cattle. Montaigu has some manufactures of woollen stuffs and leather, and five yearly fairs. Dunes has nineteen yearly fairs for cattle, corn, and linen cloth.

In the arrondissement of Castel-Sarrasin are—Castel-Sarrasin, near the right bank of the Garonne (population, in 1831, 3346 for the town, or 7092 for the whole commune; in 1836, 7408 for the commune); Verdun (population 1809 for the town, or 4234 for the whole commune), Le Mas-Garnier, and St. Nicolas-de-la-Grave, on the Garonne; St. Porquier, Scatalen, Montech, Fignan or Finhan (population 1600 for the town, or 1730 for the whole commune), and Grizalles or Grizolles (population 1724 for the town, or 2091 for the whole commune), between the Tarn and the Garonne; Bouillac, near the Lambon; Beaumont de Lomagne (population 3126 for the town, or 4130 for the whole commune), on the Gimone; and Lavit de Lomagne, near the Serre. Castel-Sarrasin suffered much in the religious wars, and the quantity of bones and of arms dug up in the neighbourhood bears testimony to the frequency or severity of the conflicts it has witnessed. The town is agreeably situated in a fertile plain about a mile from the Garonne, and is well built. The old walls and ditches have been destroyed, and replaced by agreeable promenades. The townsmen manufacture serge and other woollen stuffs, hats, and leather: there are three yearly fairs. There are one or two subordinate government offices. Verdun, distinguished from other places of the same name as Verdun-sur-Garonne, is on the left bank of the river: it has much declined from its former importance, but has still some woollen manufactures and three yearly fairs. St. Nicolas-de-la-Grave is known for the excellent melons grown in the surrounding district: there are four yearly fairs. St. Porquier is known for the extensive cultivation of tobacco and saffron in the neighbourhood: it has three yearly fairs. Grizalles or Grizolles is in a fertile plain, a short distance from the right bank of the Garonne: the townsmen manufacture a considerable quantity of cutlery, especially excellent scissars: there are three yearly fairs for cattle and horses. At Beaumont-de-Lomagne coarse cloth and other woollens, hats, and leather are manufactured, and trade is carried on in corn: there are seven fairs in the year.

The population, when not otherwise described, is that of the commune, and from the census of 1831.

This part of France, at the earliest historical period, was occupied by the Cadurci, a Celtic people, who were north of the Garumna (now the Garonne), the Tarnis (now the Tarn), and the river now known as the Tescou; by the Tolosates, also Celts, who inhabited the part south of these rivers; and by the Lactorates (of the Aquitanian stock), in whose territories that small portion of the department which lies south of the Garonne and west of the Larax or Rats was included. Perhaps some small portions of the north-western border may have belonged to the Nitiobriges, a Celtic people, and some portions of the eastern border to the Ruteni, who were also Celts: but these portions, if there were any, must have been very small. The Tasconi of Pliny, who appear to have left their name to the little rivers Teseou and Tescounet, on the banks of which they dwelt, were probably either a subdivision of the Tolosates, or a small tribe subject to them. In the Roman division of Gaul the Tolosates, with the Tasconi, were included in the province of Narbonensis Prima; the Cadurci and the Ruteni in that of Aquitania Prima; and the Nitiobriges and Lactorates in Novempopulana.

Only two places mentioned by Roman authorities are supposed to have been in this department. Cosa, mentioned in the Theodosian or Peutinger Table, was probably on the bank of the Aveyron, near Réalville; and the Fines of the same authority may be placed on the Tescou, near the junction of the Teseounet.

In the middle ages, the north-western parts, about Montaigut, Castel-Sagrat, and Valence, as far south as the Garonne, were included in L'Agenois; the northern and north-eastern parts, as far south as the Tarn, in the district of Le Bas Quercy, except just about Parisot and St. Antonin, which belonged to La Basse Marche in Rouergue; L'Agenois, Quercy, and Rouergue were all subdivisions of Guienne. South of the Garonne the whole was included in Gascogne or Gascony; the part west of the Larax being comprehended in Le Condomois, a district of Gascogne Proper; and the part eastward of the Larax in Lomagne and Rivière-Verdun, two districts in Bas (Lower) otherwise Noir (Black) Armagnac. The districts between the Garonne and the Tarn belonged to the district of Le Toulousain, or the county of Toulouse, properly so called, in Languedoc.

These territories, upon the overthrow of the Roman empire, passed into the hands of the Visigoths, from whom they were afterwards wrested by the Franks. The county of Toulouse was annexed to the crown in the reign of Philippe III. le Hardi; the county of Armagnac first by Louis XI. and finally by Henri IV., and Rouergue finally by François I. Le Quercy and L'Agenois were for a long time part of the English possessions in France. The English were finally driven out in the middle of the fifteenth century.

TARNOPOL is a circle in the eastern part of Austrian Galicia, bordering on the Russian government of Podolia. The area is about 1400 square miles, and the population 212,500, of whom about 13,000 are Jews. The surface of the country is an undulating plain broken only by a few hills. The forests are very extensive, and the soil in general extremely fertile: it produces corn, flax, hemp, tobacco, garden vegetables, and fruits. 'The fine meadows,' says Hassel, 'would enable the inhabitants to breed great numbers of cattle, but it is only the breeding of horses that is more considerable than in the rest of Galicia; they are of the true Polish race. In 1817 there were 36,273 horses, 9412 oxen, 26,339 cows, and 59,282 sheep.' According to the very detailed statistical tables for 1830 (published in 1834, which are the latest that we have seen), there were 41,223 horses, 11,156 oxen, 26,065 cows, and 81,283 sheep. There is no large river in the circle; the Podhorze forms the eastern boundary towards Russia, and the interior is watered by the Sered, the Tryna, the Guila, and other small streams.

TARNOPOL, the capital of the above circle, is a considerable town, with 10,500 inhabitants, of whom nearly half are Jews. It is situated on the river Sered, which there passes through a lake. There are in the town a Roman Catholic and a Greek church, three synagogues, a Jesuits' college, a gymnasium, and a philosophical seminary. In the year 1820, 50 of the Jesuits expelled from Russia were allowed to settle in a Dominican convent at Tarnopol. The sum of 300 florins a year was assigned to each, with a moderate sum for the establishment of the gymnasium, it being intended that they be solely employed in the education of youth in and out of the town. The inhabitants have a pretty considerable trade, but have not made much progress in manufactures. The principal establishments are tanneries. As in most Polish towns, the houses are of wood, and the streets unpaved, where filth of all kinds is suffered to accumulate.

(Hassel; Stein; Cannabich; *Mission from the Church of Scotland to the Jews*, 1842.)

TARNOW, a circle of Austrian Galicia, is bounded on the north by the Vistula, which separates it from Poland, on the east by Rzeszow, on the south by Jaslo, on the south-east by Sanok, and on the west by Bochnia. The area is 2000 square miles, and the population at present must be at least 240,000; since, according to the statistical tables for 1830, it was 238,453, of whom 14,608 were Jews. The country is an extensive plain, with here and there an inconsiderable eminence. The soil is on the whole not very fertile, in many parts sandy, and ill-cultivated. The rivers are, the Vistula on the north, the Dunajec on the west, and the Wisloka, which flows through the middle of the circle. Though the chief occupation of the inhabitants is agriculture, its operations are performed in a very slovenly manner, and the breeding of cattle is by no means in proportion to the extent of the country: the forests however are very profitable, and there is no other circle in Galicia where the people make so many wooden wares of various kinds, pipe-staves, &c. There are no manufactories, properly speaking, except in the chief town and its neighbourhood, but the country-people manufacture a great quantity of linen.

TARNOW, the capital of the circle, is pleasantly situated on an eminence near the river Biala, over which there is a handsome wooden bridge of one arch of 180 feet span, which is entirely covered over. The population of the town, without the suburb, is 2250, of whom 1650 are Jews; with the suburb the population is 4800. The houses are for the most part well built of brick, two stories high. This town is the see of a Roman Catholic bishop, and the seat of the tribunal of the circle. It has a cathedral, a Franciscan convent, a synagogue, a gymnasium, a Jewish infirmary, a military hospital, erected in 1835, and several schools. The inhabitants manufacture linen, damask, wooden-ware, and cabinet-work. They have many tanneries, and carry on a brisk trade. The cathedral contains the monuments of the princes Janusz von Ostrog, and of the counts of Tarnow-Tarnowsky: two of them are from 60 to 70 feet high, and reach to the roof of the church. These two monuments are very highly spoken of as works of art.

TARPEIAN ROCK. [ROME.]

TARPORLEY. [CHESHIRE.]

TARQUI'NII (*Ταρκυνία*, or *Ταρκυνίναι*), an antient town of Etruria, on the southern bank of the river Marta, which empties itself into the sea a few miles below. According to Strabo (v. 2, p. 355, ed. Tauchnitz), the town was founded by Tarcon, one of the companions of Tyrrhenus (Stephanus Byzant., *s. v. Ταρκυνία*; Virgil, *Æn.*, viii. 505; Silius Italicus, viii. 473); and, according to others, it was a colony of Thessalians and Spinambrians. In the reign of Ancus Marcius, Demaratus of Corinth is said to have come with a band of his countrymen to Etruria, and to have been favourably received by the Tarquinienses; and the story describes him as the father of L. Tarquinius Priscus. [TARQUINIUS.] Whatever may be thought of this tradition, it seems clear that Etruria and Tarquinii in particular experienced at an early period considerable influence from Greece. Tarquinii appears to have become in a short time a great and powerful city, as is clear from the wars which it carried on with Rome, and from the important remains which have recently been discovered; and there is little doubt that it formed one of the twelve republics of Etruria, consisting of the city and an extensive territory around it. After the expulsion of Tarquinius Superbus from Rome, in B.C. 509, the Tarquinienses were the most forward in his cause, and unsuccessfully endeavoured to restore him by force of arms. (Liv., ii. 6, &c.) About the year B.C. 397, the Tarquinienses again made war upon the Romans, and ravaged their territory, but they were defeated by A. Postumius and L. Julius. This however did not deter them from renewing their hostilities against Rome, and from making inroads upon her territory. It was on such an occasion, in the year B.C. 358, that a war broke out between the two states, which lasted for several years. The Romans in their first campaign, under the consul C. Fabius, were unsuccessful, and the Tarquinienses made 307 Roman soldiers prisoners, all of whom were sacrificed to the gods. Rome for some time carried on the war on the defensive, while her enemies acquired new allies, and invaded the Roman territory as far as the Salinæ, at the mouth of the Tiber. At last however, in 356 B.C., they were defeated by the dictator Marcius Rutilus, and the year after they were compelled by C. Sulpicius to lay down their arms. The Romans now took cruel revenge for the outrage which had been committed upon their prisoners. The common Tarquinienses who fell into the hands of the Romans were all massacred, but 358 nobles were sent to Rome, where they were beaten to death in the forum. (Liv., vii. 12-19.) Shortly after the Tarquinienses sued for a truce, which was granted for forty years. Tarquinii, like the rest of the Etruscan towns, was henceforth neutral in the wars of Rome with other nations, and remained in almost perfect independence of Rome. Shortly after the expiration of the truce the Tarquinienses obtained a peace of the same duration. At a later period Tarquinii became a Roman Municipium (Cicero, *pro Cæcin.*, 4).

The site of the antient Tarquinii is clearly discernible in the ruins still extant on the hill of Tarchino, near the modern town of Corneto. The place has in modern times acquired a peculiar interest through the numerous works of art which have been discovered in the tombs and catacombs. The first of these were opened in 1699, and what was found in them was described by Buonarotti. New discoveries have frequently been made there since that time; the most important are the paintings with which the walls of the catacombs are decorated; but besides these, thermæ and temples with inscriptions, mosaics and vases, and other works of art, are found there. Respecting these discoveries, see Wilcox and Morton, *Account of some subterraneous Apartments with Etruscan Inscriptions and Paintings, &c.*, in the *Philosophical Transactions for* 1763, vol. vii., 127; Von Stackelberg, *Aelteste Denkmäler der Malerei, oder Wandgemälde aus den Hypogäen von Tarquinii*, 1827, with numerous plates.

TARQUINIUS. According to early Roman history the family of the Tarquinii gave two kings and one consul to Rome. Its origin was traced to the town of Tarquinii in Etruria, and thence to Greece. Modern investigations

however have shown that the Tarquinii did not come from Etruria, but must originally have belonged to Latium, and that from the earliest times there existed at Rome a gens Tarquinia. (Niebuhr, *Hist. of Rome*, i., p. 373, &c.) We subjoin a list of those members of the house of the Tarquins who play a prominent part in the early history of Rome.

Lucius Tarquinius Priscus. The old story concerning his birth and his arrival in Rome ran thus:—During the tyranny of Cypselus at Corinth, Demaratus, a wealthy merchant who belonged to the noble family of the Bacchiads, was obliged by the tyrant to quit his native city. He sailed to Etruria, which he had often visited before on his mercantile voyages, and took up his residence at Tarquinii. Here he married a woman of noble rank, who bore him two sons, Lucumo and Aruns. (Dionys., iii. 46; Liv., i. 34; Polyb., vi. 2.) As an aspiring foreigner could never hope to satisfy his ambition in Etruria, Lucumo, after the death of his father and brother, resolved to emigrate with his wife Tanaquil and a numerous band of friends to Rome, where several strangers had already obtained the highest honours. He was confirmed in his expectations by a miraculous occurrence which happened just when he was approaching the city, and by the interpretation of it by his wife, who was well skilled in augury. At Rome Lucumo was favourably received by King Ancus Marcius, and lands were assigned to him. To omit nothing on his part which might characterize him as a complete Roman, he adopted the name of Lucius Tarquinius, to which subsequently the name Priscus was added to distinguish him from other members of his house. His wealth and prudence induced King Ancus to allow Tarquin to take part in all the affairs of state, and in his will he made him the guardian of his children, who were yet under age. [Ancus Marcius.] Tarquin himself aspired to become king of Rome. Accordingly, on the death of Ancus, he sent the young princes out hunting, and during their absence he held the comitia for electing a successor to Aneus, and succeeded in persuading the people to elect him, to the exclusion of the sons of Ancus, 616 B.C.

This is the common story of the descent of the fifth king of Rome, of the manner in which he came to Rome, and was raised to the throne. How much there may be historical in the tradition cannot be ascertained. Thus much however appears certain, that the arrival of Demaratus in Etruria cannot have been contemporaneous with the tyranny of Cypselus, and that, as stated above, Tarquinius was not a foreigner, but belonged to a Latin gens Tarquinia. (Niebuhr, *Hist. of Rome*, i., p. 373, &c.)

L. Tarquinius Priscus distinguished himself during his reign no less in war than in the peaceful administration of the state. His first war was against the Latins, from whom he took great spoil. With equal success he carried on war with the Sabines, whom he defeated in two great battles, and from whom he took the town of Collatia with its territory. After this he again made war on the Latins, and after he had subdued them and made himself master of many of their towns, he concluded a peace with them. During the intervals between these wars he introduced various improvements into the constitution of the state, which are mentioned in the articles Rome, p. 104, and Senatus, and which were intended to organize the body of the plebeians, and perhaps to place them on an equality with the patricians. But he could only partially carry his schemes into effect, as he was thwarted by the augur Attus Navius, who probably acted at the instigation of the patricians. After his first Latin war, Tarquin built the Circus Maximus for the exhibition of the public spectacles, and is said to have been the founder of the Roman or great games (Ludi Magni or Romani). He also assigned the ground round the forum to private individuals, that they might there build porticoes and places for transacting business; and lastly he is said to have formed the plan of enclosing the city by a stone wall, which he was prevented from accomplishing by the outbreak of the Sabine war. After the second war against the Latins, he returned to his plan, and is said to have made actual preparations for building the wall; but the completion of it was reserved for his successor Servius Tullius. The greatest work at Rome, which owes its origin to Tarquin, and which has survived all the vicissitudes of the city, are the gigantic sewers (cloacae) in the lower districts of Rome. [Cloaca.]

The sons of Ancus Marcius, who had been deprived of the throne by their guardian Tarquin, never forgot the injury, and when they discovered that it was his and Tanaquil's intention to secure the succession to Servius Tullius, they formed the design of murdering Tarquin. [Servius Tullius.] For this purpose they hired two sturdy shepherds, who went to the king's palace, and there conducted themselves as if they were engaged in a violent quarrel. At last the king himself appeared to settle their dispute, but while he was listening to one of them, the other split the king's head with an axe. Thus died L. Tarquinius Priscus, after a reign of thirty-eight years, in B.C. 578. The queen kept his death secret until the succession was secured to Servius Tullius. The assassins were seized, and the sons of Aneus fled to Suessa Pometia. (Livy, i. 34-42; Dionysius, iii. 46-73.) Tarquinius Priscus left two sons, Lucius and Aruns Tarquinius.

During the reign of this king Rome appears as a powerful state in comparison with what it is said to have been before him. According to the historians this greatness was not the result of his reign, but is supposed to have existed before it, and to have enabled him to do what he did, so that this increase of the power and dominion of Rome must have taken place previous to his reign, although we do not know how it was effected. Some traditions mentioned (Tacitus, *Annal.*, iv. 65) that under Tarquinius Priscus an Etrusean of the name of Caeles Vibenna came with a colony to Rome and settled on the Caelian hill, which derived its name from him.

Lucius Tarquinius Superbus, the seventh and last king of Rome, was the son of Tarquinius Priscus, and brother of Aruns. Tullia, a daughter of Servius Tullius, was married to the gentle Aruns, and her sister to L. Tarquinius. In concert with Lucius, Tullia murdered her own husband Aruns and her sister, and then married L. Tarquinius. Lucius placed himself at the head of a conspiracy, and murdered his own father-in-law, the aged Servius Tullius. Tarquinius, who received the surname of the Haughty or the Tyrant (Superbus), succeeded his father-in-law as king of Rome, 584 B.C., without either being elected by the people or confirmed by the senate.

There is no doubt that the hatred of the very name of king which prevailed at Rome during the republic, has greatly contributed to exaggerate the cruelty and tyranny of the last king, and thus to corrupt his history. But notwithstanding all this, it is clear that Tarquin by his talents, both as a general and a statesman, quickly raised Rome to a degree of power which it had never possessed before. The first act attributed to him after his accession is the death of all the senators who had supported the reforms of Servius Tullius, and in order to render his own person safe, he formed an armed body-guard which always accompanied him. He in fact undid all that Servius had done: he took on himself the administration of justice, put persons to death or sent them into exile according to his own pleasure, and kept the whole internal and external administration in his own hands, without either consulting the people or the senate. In order that the senate might sink into insignificance, he never filled up the vacancies which so frequently occurred through his executions, banishments, or through the natural death of senators. To secure himself still more, he formed a close connection with the Latins, to one of whom, Octavius Mamilius of Tusculum, he gave his own daughter in marriage. The influence which he thus gained among the Latins was most visible in their assemblies on the Alban Mount by the temple of Jupiter Latiaris, in which Rome also had a vote. Tarquinius, by cunning and fraud, or, according to others, by force of arms, subdued the towns of Latium and placed Rome at the head of the league (Livy, i. 50, &c.; Dionysius, iv. 45, &c.; Cicero, *De Re Publ.*, ii. 24), which was now also joined by the Hernicans and the Volscian towns of Ecetra and Antium. The wealthy town of Suessa Pometia was besieged and taken, perhaps because it had refused to join the league. The Latin town of Gabii experienced a similar fate. Sextus, the king's youngest son, went thither under the pretext of being a deserter, and contrived to put himself at the head of the Gabian army. After having put to death or sent into exile the most distinguished citizens of Gabii by the advice of his father, he treacherously surrendered the town to him. The whole account of the war with Gabii bears the character of a fable, and resembles in many respects other fabulous stories of early Grecian history. The treaty which was formed

with Gabii after its surrender, was engraved on a wooden shield, and preserved in the temple of Jupiter Fidius to the time of Dionysius of Halicarnassus. Tarquin founded in the conquered territory of the Volscians the two colonies of Signia and Circeii, by which he extended and strengthened the power of Rome.

Tarquin is said to have been fond of splendour and magnificence. He built the capitol, with the threefold temple of Jupiter, Juno, and Minerva, and adorned it with brazen statues of the gods and of the early kings. (Livy, i. 53; Dionysius, iv. 59; Pliny, *Hist. Nat.*, xxxiii. 4; xxxiv. 13.) Here he also deposited the oracular books which he had purchased from a Sibyl. [SIBYL.] After the establishment of the colonies of Signia and Circeii, a fearful omen was seen, which seemed to bode ruin to his family; and in order to ascertain its import he sent his two sons, Sextus and Arruns, accompanied by his nephew, L. Junius Brutus, to Delphi. To the question as to which of the three ambassadors was to reign at Rome, the Pythia answered: he who should first kiss his mother. Brutus, who had always assumed the appearance of an idiot, understood the oracle, and on landing in Italy, fell down and kissed the earth, the mother of all. Tarquin's coffers were now exhausted by the great works that he had undertaken, and he was tempted to make himself master of Ardea, a wealthy town of the Rutuli. As however he did not succeed in his first attack, he laid siege to the town. While this was going on, a dispute arose between the sons of Tarquin and their cousin, C. Tarquinius Collatinus, respecting the virtue of their wives. This led to the violation of the chaste Lucretia, the wife of Collatinus, who lived at Collatia, by Sextus, the king's eldest son. As the highest pride of a Roman woman at this time was her virtue, Lucretia sent for her husband, father, and Brutus, and killed herself in their presence, after having cursed the family of the king, and implored her friends to avenge the injury which she had suffered. Brutus immediately marched with an armed force from Collatia to Rome, and roused the people to avenge the indignity and throw off the yoke of their tyrant. The citizens were easily persuaded; they deprived the king, who was yet in the camp of Ardea, of his imperium, and banished him with his wife and children from Rome, 510 B.C. After these occurrences Tarquin hastened to Rome, but finding the gates of the city shut upon him, and learning that he was declared an exile, he retired to Caere, whither he was followed by his son Arruns. His other son Sextus sought a refuge at Gabii, but the citizens, remembering his former treachery, put him to death. The simple fact of the banishment of King Tarquin, which was commemorated at Rome every year by a festival called 'The King's Flight' (Regifugium or Fugalia), is beyond all doubt historical; but what is described as its immediate cause, and its accompanying circumstances, may be poetical inventions.

Tarquin however did not give up the hope of recovering what he had lost. He first sent ambassadors to Rome to demand the surrender of his moveable property. During their stay in the city the ambassadors formed a conspiracy, in which young patricians chiefly are said to have joined them. The conspirators were discovered and put to death, and the moveable property of the royal family was given up to the people, in order to render reconciliation impossible. The king is said to have found favour and protection with the inhabitants of Caere and Tarquinii, and with the Veientines, and to have led the united forces of these people against the Romans, who however defeated their enemies near the forest of Arsia. Brutus fell in this battle in single combat with Arruns. Tarquin now sought and found assistance at Clusium, which was then governed by the mighty Lar Porsenna. [PORSENNA.] During the war of this chieftain with Rome Tarquin is entirely lost sight of in the narrative of the historians; but after its conclusion we find him supported by the Latins, and waging a fresh war against Rome under the Latin dictator Octavius Mamilius of Tusculum. The battle near lake Regillus (496 B.C.), in which the king lost his only surviving son, decided the whole contest. The account of the detail of this battle is as fabulous as any part of the early history of Rome, and formed, as Niebuhr supposes, the concluding part of the 'Lay of the Tarquins.' The aged king, now deprived of all his hopes, retired to Cumae, which was then governed by the tyrant Aristodemus, where he died the year following, 495 B.C.

(Livy, ii. 19, &c.; Dionysius, vi. 2, &c.; Niebuhr, *Hist. of Rome*, i., p. 555, &c.)

LUCIUS TARQUINIUS COLLATINUS, the son of Egerius, and the husband of Lucretia. After the banishment of the king he was elected consul together with L. Junius Brutus. But the people beginning to suspect that he might perhaps be tempted to follow the example of his kinsman, and endanger the freedom of the young republic, he was compelled to abdicate, and to submit to the sentence of exile, which was now pronounced upon the whole family of the Tarquinii. (Livy, i. 57, 60; ii. 2.)

TARRAGO'NA, a province of Spain, bordering on the north on Catalonia, on the south on Valencia, and on the west on Aragon. The capital, Tarragona, is situated on the coast of the Mediterranean, on the declivity of a mountain rising to 760 feet above the level of the sea, and near the mouth of the river Francolí, 41° 7′ N. lat. and 1° 17′ E. long. Tarragona, the Roman Tarraco, is one of the most antient cities of Spain; as it is supposed to have been founded by the Phœnicians. During the second Punic War it became a Roman colony (Plin., *Hist. Nat.*, iii. 3), and, subsequently under Augustus, the capital of Hispania Citerior, or Tarraconensis, which comprised Catalonia, Aragon, Navarre, Biscay, the Asturias, Galicia, a portion of Leon, and the Balearic Islands. Tarraco was also the chief city of one of the seven conventus, or divisions of the province for purposes of administration, and chiefly for justice. In A.D. 467 it was taken by Euric, king of the Goths, and levelled with the earth. The Arabs reduced it in 710, like most cities on that coast, and it remained in their hands until Raymond IV., count of Barcelona, took it from them, about the close of the eleventh century. The city being found in a very ruinous and dilapidated state, Don Bernardo, archbishop of Toledo, undertook to rebuild it on condition that the pope would absolve him of an oath he had taken, and not fulfilled, of repairing to the Holy Land. The absolution having been granted, the archbishop of Toledo destined the greatest portion of the revenues of his see to the rebuilding of Tarragona. During the War of Succession, the English took possession of the city, which they intended to keep and began to fortify. Some of the outworks and redoubts thrown up by them are still visible. In 1810 the French, under Marshal Suchet, laid siege to it, and took it by storm on the 20th of June, 1811, after a siege of several months. The conduct of the French commander on this occasion is greatly to blame; he not only justified, but even encouraged, the perpetration of all kinds of atrocities, on the ground that he wished by one dreadful example to terrify the people and prevent all further resistance. An attempt to retake the city, made in June, 1813, by the allied forces under General Sir John Murray, failed completely; for at the approach of Suchet, who was advancing from Valencia, that officer raised the siege and re-embarked his troops with such precipitation that he left all his artillery and stores behind.

Tarragona is tolerably well built, and the Roman remains render it interesting. Besides the circus, which is now almost entirely built upon, it has a very fine amphitheatre, in a good state of preservation, and a large Roman building, probably a temple, which the inhabitants call 'the palace of Augustus.' The remains of a splendid aqueduct, which once supplied Tarragona with water, which was brought from a distance of 16 miles, afford likewise a proof of the importance of the city under the Romans. About three miles east of the city there is a very fine mausoleum, which the vulgar call 'El Sepulcro de los Scipiones' (the tomb of the Scipios), from a belief that Cnæus and Publius Scipio are buried under it. Of the Moorish domination there remain no other traces than a large building close to the sea, which is believed to have been their arsenal. The cathedral is by far the most interesting building in the city, and is well deserving of attention for its vast dimensions and the elegance and purity of its Gothic architecture. It was erected in the year 1117, but has since been greatly added to. The chapel of Santa Theela, which is entirely built of rich marbles and jaspers, is one of the richest and most tastefully decorated in the church. The great altarpiece too is much admired for its exquisite carvings, executed by a native artist in 1426. Tarragona is the see of an archbishop, who once disputed with that of Toledo the primacy of Spain. During the Moorish domination, several provincial and general councils were held there. At the first, which took place in 816,

it was ordained that the Sabbath should commence on Saturday night. The immediate neighbourhood of Tarragona is well cultivated, and yields corn, wine, oil, and hemp, in great abundance. The principal manufactures are cloth, coarse cotton-goods, hats, and cutlery, which are exported to all parts of Spain, and to the island of Cuba.

TARSHISH (תַּרְשִׁישׁ) is a place mentioned in the Old Testament, particularly in connection with the commerce of the Hebrews and Phœnicians. In *Gen.*, x. 4, the name occurs among the sons of Javan, who are supposed to have peopled the southern parts of Europe. (Compare *Ps.* lxxii. 10; *Isaiah*, lxvi. 19.) In other passages it is mentioned as sending to Tyre silver, iron, tin, and lead (*Ezekiel*, xxvii. 12; *Jerem.*, x. 9); and from *Isaiah*, xxiii. 10, some have inferred that it was subject to the Phœnicians. The prophet Jonah, attempting to avoid his mission to Nineveh, fled from Joppa in a ship bound to Tarshish. (*Jonah*, i. 3; iv. 2.) In several passages of the Bible 'ships of Tarshish' are spoken of, especially in connection with Tyre; and it is pretty generally agreed that that phrase only describes a species of large ship, such as those used in the trade with Tarshish, just as we speak of 'Indiamen.'

From a comparison of the above passages, the majority of critics have concluded that Tarshish must be sought for in the western part of the Mediterranean, or even outside the Straits; and it has been generally identified with the Phœnician emporium of Tartessus in Spain, a place which would undoubtedly furnish the products said to have been brought from Tarshish. The Phœnician name 'Tarshish' would easily become the Greek Ταρτησσός; in fact the Aramæan pronunciation of 'Tarshish' would be 'Tarthesh.' We have abundant proofs that the Phœnicians had established an extensive commercial intercourse with Spain at a very early period.

But there is a considerable difficulty about the position of this Tartessus. The ancient geographers place it, some at the mouth of the river Baetis (Guadalquivir), the most ancient name of which river they state to have been also Tartessus; while others identify it with the city of Calpe, or Carteia, near Mount Calpe, the rock of Gibraltar. (Herod., iv. 152; Strabo, p. 140, 148-151; Mela, iii. 6; Plin., iii. 1; Pausan., vi. 19; Steph. Byzant., *v.* Ταρτησσός.)

The best way to explain and reconcile these statements with each other, and with the biblical accounts respecting Tarshish, seems to be by taking the latter as the name not of a single place, but of the whole country in the neighbourhood of Gibraltar. In this district there may have been more than one city bearing a name like Tartessus. The name survives in various forms in the names of the rock Calpe, of the neighbouring city Calpe, Carpe, or Carteia (for it is written in all these ways), and of the people Carpetani. This statement will be more clearly understood after a reference to the articles on the letters C, P, and T. In confirmation of this view, Strabo states that the country in the neighbourhood of Calpe was called Tartessis.

Respecting the difficulty arising from the conjoint mention of Tarshish and Ophir in the book of *Chronicles*, see OPHIR.

TA'RSIUS, Storr's name for a genus of QUADRUMANA.

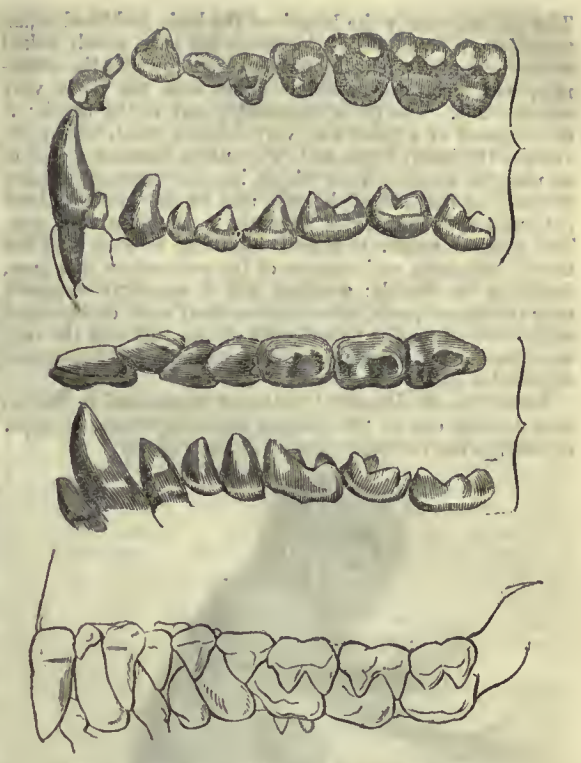
Generic Character.—Head rounded; muzzle short; eyes very large; posterior limbs very much elongated, with the tarsus thrice as long as the metatarsus. Tail long.

Dental formula:—incisors $\frac{4}{2}$; canines $\frac{1-1}{1-1}$; molars $\frac{6-6}{6-6}$ = 34.

Example, *Tarsius Bancanus*.

Description.—Dr. Horsfield remarks, that although the Tarsius from Banca agrees in the essential points with the other species of this singular genus which have hitherto been discovered, it has no intermediate front teeth, and the exterior tooth on each side is, compared with the other species, very minute. Counting (with Desmarest) one canine tooth on each side, above and beneath, it has, says Dr. Horsfield, only five grinders in each jaw.

'The head,' continues Dr. Horsfield, 'in proportion to the size of the body, is large; the arch of the forehead rises high, and the occiput is regularly spheroidal. The proximity of disposition and excessive size of the eyes is equally characteristic in this as in other species. The



Teeth of Tarsius, much larger than the nat. size. (F. Cuv.)

Front view of the teeth of Tarsius Bancanus. (Horsf.)

rostrum, or extremity of the face, is short and obtuse; the nose is slightly rounded, almost flat above; and the nostrils, as usual in this genus, are pierced laterally. The ears, which from their erect position and their projection beyond the cranium give a peculiar distinctive character and appearance to the other species, in our animal are disposed horizontally, and instead of rising up towards the crown of the head, incline backwards and extend but little from its sides; the lobes, as usual, are very thin, membranous, semitransparent, thinly beset with delicate hairs; several tufts of longer hairs arise from the base, where the interior membranaceous lobules are discovered, but in our specimen too much contracted to admit of a detailed description. The neck is very short, and the anterior extremities have the same proportion to the body as in the other species. The hands are externally covered with a very soft down; internally they are naked, and provided with several rather prominent protuberances, which, according to the opinion of Mr. Fischer, are calculated to assist the animal in climbing. The fingers are deeply divided and very delicate; those of the hands have the same proportion, one to the other, as they have in man; on the feet they are more lengthened and slender; the third finger is longer than the middle finger, and the thumb is proportionally short. In all the third phalanx is somewhat thickened, and surrounded by a projecting orbicular border, which, in the thumb particularly, constitutes a delicate ball, supporting the nail. The nails of all the fingers of the hand, as well as of the thumb and the third and fourth finger of the feet, are triangular, and represent a delicate compressed scale: on the index and middle finger of the feet they are erect, sharp, compressed, slightly curved, and not inaptly compared by Mr. Fischer to the thorns of a rose-bush, constituting one of the essential characters of this genus. The body is handsomely formed, and, as in the other species, somewhat contracted towards the pelvis; the lower extremities also have in general a similar character, but the tarsus has less of the extravagant length which is common to the other *Tarsii*.

The tail has nearly the length of the body and head taken together; it is somewhat thicker at the base, nearly naked two-thirds of its length, but covered towards the extremity with a soft down, which forms, near the tip, a very obscure tuft. The fur is remarkably soft to the touch; it is composed of a thick and very delicate wool, which envelopes the body, head, and extremities, forming a coat of an unequal surface, from which irregular straggling hairs project; at the root of the tail, and at the hands of both extremities, it terminates abruptly in the form of a ring. The general colour is brown, inclining to grey; on the breast, abdomen, and interior of the extremities it is grey, inclining to whitish: a rufous tint is sparingly dispersed over the upper parts, which shows itself most on the head and extremities: the naked parts of the tail near the root are considerably darker than the extremity.' (*Zoological Researches in Java.*)

Locality.—Dr. Horsfield obtained this animal in Banca, near Jeboos, one of the mining districts, where, he says, it inhabits the extensive forests in the vicinity.

Tarsius Bancanus. (Horsf.)

M. F. Cuvier remarks that the dentition of the *Tarsier* approximates the animal more to the *Galeopitheci*, and even to the bats, than to the *Quadrumana*. The bones of this genus are well represented in the excellent *Ostéographie* of M. de Blainville.

TARSUS, now TERSOOS, a town on the Cydnus, situated in Itshili, a division of Caraman, and formerly one of the chief towns of Cilicia. It is about twelve miles distant from the sea, and is in 37° N. lat. and 34° 50′ E. long. The traditions about its origin are various. It has been supposed to be the Tarshish of Scripture, but neither Bochart nor Vincent (*Commerce of the Ancients*) countenances this conjecture. Stephanus Byzantinus (*v.* Ταρσός) says it was founded by Sardanapalus (see the inscription on the tomb of that monarch, Strabo, 672, ed. Casaub.). Ammianus, l. xiv., c. 28, and Solinus, *Polyhist.*, c. xli., assert that Perseus was the founder (Lucan, iii. 225), and the name Tarsus has been derived from the fable that his horse Pegasus lost a hoof (Ταρσός) there. (Dionys. Perieget., 868, et seq., and for other fanciful derivations see Stephanus Byz.) Strabo relates that it was a settlement made by those who accompanied Triptolemus from Argos in his quest of Io (p. 750, ed. Casaub.). The first historical notice of Tarsus after this is in Xenophon, *Anab.*, i. 2), who describes Tarsus as a great and flourishing city when it was taken and plundered by the younger Cyrus, who afterwards concluded a treaty with Syennesis, king of Cilicia, who had his palace there.

We learn from Curtius (iii. 4), that Alexander the Great arrived at Tarsus just in time to save it from being burnt by the Persians. In later times the inhabitants joined the party of Julius Cæsar, in honour of whom they took the name Joliopolis; they were in consequence severely punished by Cassius, and rewarded afterwards by Antony, who made Tarsus a free city. (Dion, 47, 342, 344, fol., Hamb., 1750.) Tarsus enjoyed the favour of Augustus, whose tutor Athenodorus, a Stoic, was a native of this place, and persuaded the emperor to release his countrymen from all taxation. (Lucian, *Macrob.*, 21, Lehmann, 1839.) Athenodorus, returning to his native place in his old age, expelled a troublesome faction, at the head of which was Boethus, an unprincipled demagogue, and remodelled the constitution. (See Strabo, p. 674, who gives some curious details.) He was succeeded in his government by Nestor, an Academician.

Tarsus continued to flourish under the emperors, under whom it assumed the several titles—Hadriana, Commodiana, Antoninopolis, Macriniana, Alexandriana, Alexandrinopolis, and finally, in the time of Valerian, Hadriana, Severiana, Antoniniana. (Eckhel, *Doct. Vet.*, III., 'Tarsus.') The Tarsians, according to Strabo, excelled in quickness of repartee and every kind of ready wit; and their schools of philosophy were not less celebrated than those of Athens and Alexandria. The chief among the Stoics were the two Athenodori; among the Academicians, Nestor. Athenæus (v., 215, ed. Casaub.) speaks of Lysias, an Epicurean, who was tyrant of Tarsus at some time. The coins of this city inform us of its relations with Cilicia and the adjacent provinces. The inscriptions ΚΟΙΝΟΣ ΚΙΛΙΚΙΑΣ, on a decastyle temple; ΚΟΙΝΟΣ ΤΩΝ ΤΡΙΩΝ ΕΠΑΡΧΙΩΝ, referring to the games common to the three provinces of Isauria, Caria, and Lycaonia, are to be found in Mionnet, *Recueil des Médailles*, iii. That it was a metropolis appears from an inscription on a coin, ΜΗΤΡΟΠΟΛΕΩΣ ΤΥΧΗ, and from the testimony of Strabo; and Appian's statement that it was a free city is confirmed by the title ΕΛΕΥΘΕΡΑ. St. Paul was a native of this place. (*Acts*, xvi. 37; and xxii. 25-28.) Other interesting types and inscriptions occur on the coins of Tarsus. On those of Septimius Severus there is ΣΕΒΗΡΕΙΑ ΟΛΥΜΠΙΑ ΕΠΙΝΕΙΚΙΑ, recording his victory over Pescennius Niger in Cilicia. Jupiter Nicephorus, Apollo, Hercules engaged in several of his labours, Perseus with the harpa, are frequent types, and confirm the testimony of Dion Chrysostom (*Orat.*, 33, 20), who mentions these among the chief deities of the place.

The figure of Triptolemus, the reputed founder, also occurs; and the name ΒΟΗΘΟΥ, referring perhaps to the demagogue of that name. The imperial series extends as low as Gallienus, and contains some silver coins, a proof of the great wealth and importance of Tarsus. In the Synecdemos of Hierocles, Tarsus is placed in the Provincia Ciliciæ Prima, and styled Metropolis; Constantine Porphyrogennetus (lib. ii., *Them.* 13) places it in the Theme of Seleuceia, and adds, that it was an important outpost for the Arabs. It had been seized by them during the early times of their empire, and had been strongly fortified by Harun al Rashid, whose son and successor Al Mamun, was buried there, A.D. 833. It was recovered by Nicephoros Phocas, the successor of Constantine Porphyrogennetus, after a great resistance. (Leo Diacon., iv. 3, &c.) Ebn Haukal, an Oriental geographer, who wrote in the tenth century, thus describes it:—'Tarsous is a considerable town, with a double wall of stone. The inhabitants are valiant men, horsemen, and fond of warlike achievements. It is a strong and pleasant place. From it to the borders of Roum are many hills and mountains of difficult ascent. They say that in Tarsous there are above a thousand horsemen; and in all the chief cities of Islam, such as Seistan and Kirman, and Pars, and Khuzistan, and Irak, and Hejaz, and Egypt, there are inns, or public places, appointed for the people of this town.' (Ouseley's Translation, p. 46.)

Tarsus was afterwards retaken by the Arabs, but it was wrested from them by the Crusaders, under the command of Tancred, the nephew of Boemond, who resigned his conquest to Baldwin, afterwards count of Edessa. (Guibert de Nogent, *Histoire de la Première Croisade*, iii. 108; Guizot, *Mém. relat. à l'Hist. de France*, ix.) William of Tyre describes it at this time as a metropolis of Cilicia, with suffragan towns, and a population of Greeks and Armenians, much oppressed by the Arabs. Albert d'Aix says that it was populous, and well fortified. In the

twelfth century Benjamin of Tudela speaks of it as the limit of the Greek empire (i. 58, Asher's translat.); and in the thirteenth, during the eallphate of Mostazem, the Arabs attempted to recover Tarsus, but failed. (Abulpharagius, p. 160, ed. Pococke, Oxon., 1673.) It was finally taken by Mohammed II., in 1458. (Von Hammer's *Geschichte des Osmanischen Reiches*, ii. 35.)

Very few remains of the antient city of Tarsus exist: at the north-west end of the antient town is part of an old gateway, and near it a very large mound, apparently artificial, with a flat top, from which is an extensive view of the adjacent plain: on an eminence to the south-west are the ruins of a spacious circular edifice, probably the gymnasium. Lucas, who visited it in 1704, only noticed one inscription, which he gives (i. 271-2, Amster., 1714). For the probable situation of the tomb of Julian, see Rennel, *Western Asia*, 88, &c. On a rock three or four leagues from Tarsus is a fortress, called the Castle of Giants. Kazalu, the port of Tarsus, is now about twelve miles distant, and is closed up by a sand-bar. (Beaufort's *Survey of Caramania*, 276.) The population of Tarsus is about 6000, chiefly Greeks and Armenian Christians, governed by a Moosellim: its site is unhealthy. For further information, see Michaud and Poujoulat's *Correspondence d'Orient*, vii., 146.

TARTA'GLIA, NICHOLAS, a learned Italian mathematician, who was born at Brescia about the beginning of the sixteenth century. When he was six years of age his father, who followed the humble occupation of a messenger, or carrier, died, leaving him in indigent circumstances, and without education. Even his family name is unknown, and that which he bore (designating one who stammers) was given him in derision by his young companions in consequence of an impediment in his speech arising from a wound which he received on his lips from a soldier, when the French army under Gaston de Foix relieved Brescia in 1512.

No account has been transmitted of the means by which Tartaglia obtained a knowledge of the rudiments of science, and it is probable that he owed but little to a preceptor. His own exertions, aided only by a mind endowed with the power of readily comprehending the processes of mathematical investigation, enabled him at length to attain the highest rank among the geometers of his time. Having passed several years as a teacher at Verona and Vicenza, he was appointed professor of mathematics at Brescia, and in 1534 he removed to Venice, where he held the like post till his death, which took place in 1557.

Tartaglia wrote on military engineering and on natural philosophy, but it is on his talents as an algebraist that his fame principally rests. In that age it was the custom for mathematicians to send difficult propositions to each other for solution, as trials of skill; and in the work entitled 'Quesiti ed Inventioni Diverse,' which Tartaglia published in 1546, there are contained some interesting accounts of the circumstances connected with the algebraic questions which he had received and answered. Among these are his investigations relating to equations of the third degree; and the solutions of two cases, in which both the second and third powers of the unknown quantity are involved, are shown to have been discovered in 1530, on the occasion of a question proposed by a person who kept a school at Brescia: Tartaglia states also that, in the year 1535, he found out the solutions of two equations, in which the first and third powers of the unknown quantity enter without the second, while preparing himself for a public contest with Antonia Maria Fiore, who then resided at Venice, and who had challenged him to a competition, in which each was to solve as many as he could of thirty questions to be proposed by the other. It is added that Tartaglia, in two hours, answered all those of his opponent without receiving one solution from the latter in return.

In 1539, Cardan, who had been informed of the discoveries of Tartaglia, applied to the latter for the solution of certain questions which he proposed, in the hope of obtaining from him a knowledge of the processes which he employed in obtaining the roots of equations of the kind just mentioned. The application was made at first through a bookseller, and afterwards by letter; but Tartaglia, who, by the possession of his secret, enjoyed great advantages over the other mathematicians of the time in resolving the questions which were proposed to him, declined making any communication by which his method might become publicly known. Though disappointed in these attempts, Cardan soon afterwards succeeded, by a promise of introducing him to an Italian nobleman, who had the reputation of being a great patron of learned men, in inducing Tartaglia to make a visit to himself at Milan: the latter, while there, yielded to the entreaties of his host, and having exacted a promise of inviolable secrecy, gave him a key to the rule which he had discovered. Cardan immediately found himself embarrassed with what is called the irreducible case, in which the expression $\frac{1}{4}Q^2 - \frac{1}{27}P^3$ [IRREDUCIBLE CASE], entering into the value of the unknown quantity under the sign of the square root, is negative, and he applied to Tartaglia on the subject: the latter however declined giving a direct answer to his inquiry, being himself unable to conquer the difficulty; in fact the solution of the equation in this case is even now usually obtained by the aid of trigonometrical functions.

In the work of Tartaglia above mentioned there is an account given of a dialogue which took place in 1541 between himself and a Mr. Richard Wentworth, who then resided at Venice, and to whom it appears that Tartaglia had given lessons in mathematics. On being pressed by that gentleman to give him the rules for the solution of equations containing the second and third powers of the unknown quantity, the Italian mathematician declined doing so, on the plea that he was about to compose a work on arithmetic and algebra, in which the rules, he said, were to appear.

In 1545 Cardan published his work entitled 'Ars Magna,' and, in direct violation of his solemn promise, gave in it the rule for the solution of the cubic equation containing the first and third powers of the unknown quantity. He does not assert that he is the discoverer of the rule, but observes that it was first found out about 30 years previously by Scipio Ferreus, of Bologna; and adds that it had since that time been independently discovered by Tartaglia. The publication of this work produced, as might be expected, the most animated remonstrances from the man who thus felt himself seriously injured and aggrieved: Tartaglia however revenged himself in no other way than by sending challenges to Cardan and his disciple Lewis Ferrari, to hold with him a disputation on mathematical subjects, by which the public might be judges of their several merits. The discussion actually took place in 1549, in the church of Santa Maria, in Milan, between Tartaglia and Ferrari; but during the sitting, on the former pointing out an error which had been committed by Cardan in the solution of a problem, the people, who appear to have taken the side of their townsman, excited a tumult, and the assembly broke up without coming to a decision. Tartaglia has received no more justice from posterity than he experienced from his cotemporaries, and the formula for the value of the unknown quantity in such equations is still designated Cardan's rule. It must be admitted however that Cardan was the first who published its demonstration.

The works of Tartaglia, all of which were published at Venice, are—'Nuova Scienza; cioè Invenzione nuovamente trovata, utile per ciascuno speculativo Matematico Bombardiero,' &c., 1537: this is a treatise on the theory and practice of gunnery, and it was translated into English in 1588. 'Euclide, diligentemente rassettato,' &c., 1543: this is said to be the first Italian translation of Euclid. 'Archimedes Opera emendata,' &c., 1543. 'Quesiti ed Invenzioni Diverse,' 1550: this is the work above mentioned, and it is dedicated to Henry VIII. of England: it contains the answers to questions which had been proposed to Tartaglia concerning mechanics and hydrostatics; and to one of the books there is a supplement concerning the art of fortifying places. 'La Travagliata Invenzione, ossia, Regola per sollevare ogni affondata Nave,' &c., 1551; 'Ragionamenti sopra la Travagliata Invenzione,' 1551; 'General Trattato de' Numeri e Misure,' 1556-1560; 'Trattato di Aritmetica,' 1556; 'Descrizione dell' Artifiziosa Macchina fatta per cavare il Galeone,' 1560; 'Archimedis de Insidentibus Aquæ Libri duo,' 1565; 'Jordani Opusculum de Ponderositate,' 1565. A collection of his principal works was published in 1606.

TARTAN.. [WEAVING.]

TARTAR. [POTASSIUM.]

TARTARIC ACID. This acid was first obtained in a separate state by Scheele; it exists in several vegetable

products, but principally in hi-tartrate of potash, which is usually called *cream of tartar*, a salt which is deposited from wine.

The tartaric acid of this salt is obtained first by converting the excess of it, one half of it, into tartrate of lime by the addition of chalk, and the other half into the same salt by means of chloride of calcium; the resulting tartrate of lime is decomposed by sulphuric acid, by which sulphate of lime is precipitated, and the solution of tartaric acid thus obtained by single elective affinity and decomposition is evaporated, and crystals of the acid are deposited on cooling.

The properties of tartaric acid are, that it is colourless, inodorous, and very sour to the taste; it occurs in crystals of a considerable size, the primary form of which is an oblique rhombic prism; it suffers no change by exposure to the air; water at 60° dissolves about one fifth of its weight, and at 212° twice its weight; the solution acts strongly on vegetable blue colours, turning them red, and it becomes mouldy and decomposes when long kept; alcohol dissolves it, but more sparingly than water. The crystals, when heated a little above the boiling-point of water, melt into a liquid, which boils at 250°, leaving on cooling a semi-transparent mass, which is rather deliquescent; if it be more strongly heated in a retort, tartaric acid is decomposed, and converted into pyrotartaric acid, accompanied with some other products. When very strongly heated in the air, a coaly mass is procured, which is eventually dissipated. Sulphuric acid acts upon and decomposes tartaric acid, with the production of acetic acid; by means of nitric acid it also suffers decomposition, and a portion of its carbon, by acquiring oxygen from the decomposed nitric acid, is converted into oxalic acid.

Solution of tartaric acid acts with facility upon those metals which decompose water, as iron and zinc; it combines readily with alkalis, earths, and metallic oxides; and these salts are called *tartrates*. For an account of the more important of these we refer to the respective bases. Tartaric acid has a remarkable disposition to form double salts, one of the most distinct and remarkable of which is the tartrate of potash and soda, which has long been employed in medicine under the name of Rochelle Salts.

Tartaric acid free from water, in which state it may be obtained by exposure to a heat of 302° in an oil-bath for some time, consists of

Two equivalents of hydrogen	2	or 3·4
Four equivalents of carbon	24	„ 36·4
Five equivalents of oxygen	40	„ 60·6
Equivalent	66	100·

It is insoluble in cold water.

In the crystallized state it consists of—

One equivalent of anhydrous acid	66	or 88
One equivalent of water	9	„ 12·
Equivalent	75	100

By the action of heat, so as partially to decompose it, tartaric acid is converted into tartrelic acid and tartralic acid, which are not of sufficient importance to require description.

Tartaric acid is largely employed as a discharge in calico-printing, and for making what are called sodaic powders, which are extemporaneous imitations of soda-water.

TARTARIC ACID is entirely confined to the vegetable kingdom, and is found free or uncombined in tamarinds, in the unripe grape, and in pepper; and in combination in tamarinds, ripe grapes, gooseberries, mulberries, squill, dandelion, chenopodium vulvaria, in various species of pines, and as tartrate of lime in the fruit of the Rhus typhina. For medical purposes it should be remarkably pure, when it is without odour, but makes a powerful acid impression on the organs of taste. In small doses, properly diluted, it acts as a refrigerant, and is of much value in fevers, particularly mucous, and in biliary remittents. It excites the appetite of persons in whom the stomach is in a healthy condition; and those who, by long indulgence in stimulating food and drinks, experience loss of appetite, painful digestion, constipation, with a yellow and altered countenance, and diminished muscular power, find in tartaric acid a remedy of singular power. For this state of system a few crystals should be dissolved in two small tumblers, and drank in the morning fasting, an hour intervening between the tumblers. A few grains are sufficient for each tumbler, as when made too strong it excites irritation, followed by purging. Occasionally it disturbs the nervous system in a distressing way, so that patients refuse to continue its use. This plan has in many instances reclaimed individuals addicted to habitual intoxication, to which they have recourse to relieve a painful feeling of sinking and craving of the stomach, which is effectually removed by the acid draught. This is also useful after an attack of *delirium tremens*.

Tartaric acid enters the circulation, and diffuses itself through the whole body, and may be recognised in the urine, generally in combination, often with lime. Tartaric acid is much used to decompose alkaline carbonates, and form effervescing draughts, the employment of which requires caution. [ANTACIDS.]

TARTARS, or, more correctly, TATARS (Khazars and Kiptshak). The name Tatars once designated a great number of different nations in Middle Asia and Eastern Europe, which, according to general opinion, were of one common origin. Careful research however into their history, language, and ethnographical relations, has shown that the name of Tatars never designated any particular race, although it was at first restricted to certain tribes, among which there was no difference of race. It has however gradually become a collective name, under which are comprehended different nations of Mongol, Turkish, and even Finnish origin. The numerous errors and the inextricable confusion in the earlier historians who have written on this subject can only be cleared up by going back to the historical origin of the name of Tatars.

As early as the beginning of the ninth century, the Chinese knew a people called Tâta, who lived to the east and south-east of the lake of Baikal, towards the upper part of the river Amur. They were also called Tatoöl, the Chinese pronunciation of Tatar, and they are probably identical with the Taidjod of the Mongol historian Sánang-Setsen. In the middle of the tenth century the Tatars were divided into three tribes, the White, the Wild, and the Black or Water Tatars, the last of which lived about the sources of the Amur, and were subject to the White, until Insugay (Yessugay), the father of Genghis Khan, a prince of the Water Tatars, subdued the White Tatars, in the middle of the twelfth century. He then united the Wild and all the other tribes of his race; and his son Genghis Khan gave to these warlike nations, the general name of which seems to have been Bede, the name of Köke-Mongols, that is, the Blue Bold, or the Celestial Mongols. A particular circumstance made the change of their name agreeable to his subjects. The word Tatar signifies in the Mongol language 'a tributary people,' and, in consequence, could not be agreeable to nations which had not only ceased to be tributary, but boasted of the noble title of Mongols. (Sánang Setsen, *History of the Eastern Mongols*, ed. J. J. Schmidt, p. 71, and notes 21 and 22; Pallas, *Sammlung Historischer Nachrichten über die Mongolischen Völkerschaften*, vol. ii., p. 429; Schmidt, *Forschungen im Gebiete der Völker Mittel Asiens*, p. 59.)

When Genghis Khan sent his son Tushi Khan to conquer the west, all the Turkish nations which were scattered over Middle Asia, from the sources of the Amur to the Caspian, were subjugated, and thus became Tatars, that is, tributary subjects of the Mongol empire. Eastern Europe, inhabited by other Turks and numerous nations of the Finnish race, shared their fate; the tributary inhabitants were obliged to fight under a Mongol chief; and the names of Mongols and Tatars were not only confounded, but the latter soon gained the ascendency, because it designated the great majority of Mongol subjects. In 1223, when the Mongols made their first invasion of Russia, they were generally called Tatars; and when Batu, the grandson of Genghis Khan, after having laid waste Russia and Poland, appeared on the frontier of Germany, the emperor Frederic II. summoned the princes to rise against the Tatars. The battle of Wahlstatt, or Liegnitz, was fought on the 9th of April, 1241, in which the Mongols, although they defeated a feeble army of Poles and Germans, were so struck with the heroic resistance of the Teutonic knights, that they did not advance any farther. This battle was for some time generally called the Tatar Battle: seven Silesian nobles who survived that day had and have still Tatar-caps in their armorial bearings; and another German knight, whose descendants are still living, had his name

changed in commemoration of the day; but his new name was not Mongol, but Tader. A further proof of the great numerical preponderance of the tributary nations over the true Mongols is, that an army of 660,000 men, with which Batu occupied Russia and the Ural country, contained only 160,000 Mongols; while 500,000 belonged to the subdued Turkish, Finnish, and Slavonic nations. (Hammer, *Geschichte der Goldnen Horde in Kiptshak*, p. 114, 115, 141; Karamsin, iii., p. 275.)

These well-known facts, which might easily be augmented, are sufficient to prove that the name of Tatars was first known in Europe in its etymological signification; that it got a political signification, and was applied to nations which were not of Mongol origin; and that it had lost all precise ethnographical signification even before it reached the West. Tatars became a general name for any nomadic and barbarous hordes which invaded Europe from Western Asia, and thus it appears why in Sweden the gipsies were once known under the name of Tattars, and why in the duchy of Holstein they are still called either by the name of Zikhainers or by that of Tatars. (Benzelius, *Epitome Commentariorum Moysis Armeni*, Stockholm, 1723, 4to., p. 89.)

The incorrect orthography Tartars occurs as early as the appearance of the Mongols in Europe, and was probably introduced by superstitious monks and writers, who, struck with the seeming analogy between Tatar and Tartarus, believed them to have come from the infernal regions. This at least is more probable than the opinion that the name Tartars was introduced by Saint Louis, who, in a letter to his queen Blanche, about the approaching danger of the Tatars, speaks of them in the following terms:—'This divine consolation will always exalt our souls, that in the present danger of the *Tartars* either we shall push them back into the Tartarus whence they are come, or they will bring us all into heaven.' (Klaproth, *Asia Polyglotta*, p. 202.) These words rather prove that in King Louis's time the name and its origin were known.

If the empire of Genghis Khan had lasted longer, the name of Mongols would certainly have prevailed over that of the tributary nations, in the same way as that of the Franks supplanted the names of the Gauls, the Romans, the Goths, and the Burgundians. But the name of Mongols disappeared in Europe, and was no longer heard of except in the remote deserts of eastern Asia. The old name of Tatars however lasted as a designation of the different inhabitants of the empire of Kiptshak, which was founded by the descendants of Genghis Khan on the frontiers of Asia and Europe. There the princes only and part of the nobles were Mongols, and they were sometimes called so by those foreigners who were able to perceive the ethnographical differences among the inhabitants of Kiptshak (Treaties between Venice and the Golden Horde, cited below), but the remaining population was composed of Turkish and Finnish tribes, of which the former were the more numerous. The Russians, who were under the dominion of the Mongols for above two centuries, knew the Finnish tribes by the name of Tshudes, and their application of the name of Tatars exclusively to the Turks of Kiptshak gave rise to the present signification of the name. The other nations of Europe were less able to make such distinctions. Thus, for instance, Olearius, the secretary to the duke of Holstein's embassy to Persia, says, in his 'Travels,' that Moruma (Murom on the Oka) was 'the first town of Tartary on the way from Moscow, and that at Wasiligrod, at the entrance of the Sura into the Wolga, began the country of those Tatars who are called Tsheremisses.' But Murom is situated just at the entrance of the country of the Mordwins, one of the oldest Finnish tribes known to history, and the Tsheremisses are likewise of Finnish origin. Nevertheless Olearius calls them Tatars. He observes however that their language had a particular character, and resembled neither the Turkish nor the Tatar language, an observation which proves that Tatar has here two meanings: it first designates the inhabitants of the conquered territory of Kiptshak (Tartary), and then in a narrower sense the Turkish inhabitants of that country.

At present the name of Tatars is still given to the Turkish inhabitants of southern and eastern Russia, and as their origin is well known, there is no more reason for dropping the name for that of Turks, than there is for refusing the French their name, and calling them Gauls. It is nevertheless an important fact that the Tatars call themselves Turks, and feel highly offended by being called Tatars, a name which in their idiom signifies 'robbers.' This fact refutes the hypothesis of Klaproth, who believes that the subjects of the Mongol empire adopted the name of Tatars as a title of honour, on account of its being the antient name of the chief tribe of the ruling nation. Klaproth's opinion becomes also entirely untenable if put in connexion with a fact stated by Sherefeddin and Arabshah, who tell us that Timur, who, as a descendant of Genghis Khan, undoubtedly belonged to the Mongol race, in a letter to Báyazid, calls himself a Turk, upbraiding this sultan of the Osmanlis with being a vulgar Turkoman. Can we believe that the subdued nations should have distinguished themselves by an ignoble name of their masters, while these, at the same time, made a boast of that of their Turkish subjects! It must be repeated that the tributary nations were called Tatars by the Mongols and by foreigners, and disliked the name on account of its meaning; and that the ethnographical signification of it was supplanted by the general and glorious name of Mongols. [TURKS.]

This account of the origin and the gradual diffusion of the name Tatar is more or less different from those given by Klaproth, Abel Rémusat, and Schmidt, but it is founded entirely on facts the knowledge of which we owe to these authors, and especially to Julius von Klaproth. Besides the above-cited works, the reader may consult Schmidt, in Hammer, *Fundgruben des Orients*, vol. vi., heft 3; Klaproth, *Beleuchtung und Widerlegung der Forschungen des Herrn Schmidt;* Abel Rémusat, *Recherches sur les Langues Tartares;* Abulghasi Bayadurkhan, *Histoire Généalogique des Tartars*, Leyden, 1726, 8vo.; Ahmedis Arabsiadae, *Vita et Res gestae Timuri*, ed. Manger, ii., cap. 19; Sherefeddin Ali, *Hist. de Timour Bey*, trad. par Pétis de la Croix, l. v., c. 14.)

The above-mentioned Turkish nations were known in history long before they were called Tatars. Part of them founded the empire of Khazaria, between the Dniepr and the Yaïk.

The *Khazars*, the Ghysser or Ghazar of Moses of Khorene, inhabited in the time of this Armenian author, in the fifth century A.D., the country north of the Caspian Sea; and in the sixth century they penetrated into the countries north of the Kuban and the Black Sea, where they founded a powerful empire. Among the Byzantine historians, Theophanes is the first who mentions them. As early as A.D. 625 they allied themselves with the emperor Heraclius, and in conjunction with him attacked Anushirwan, the king of Persia, and from that time were in continual political intercourse with the Byzantine emperors, who were always anxious to maintain peaceful relations with this people. Contemporary historians state that the Khazars consisted of two principal races: one of them was little, ugly, with black hair, and probably of Finnish origin; the other was tall and handsome, and spoke a Turkish dialect: many other races however were mixed up with them, so that Leo Diaconus justly calls them a 'colluvies gentium.'

(Ouseley, *Oriental Geography of Ebn Haukal*, pp. 185-190; Frähn, *Veteres Memoriæ Chazarorum ex Ibn Toszlano, &c.*; *Mémoires de l'Académie de St. Pétersbourg*, vol. viii.; Theophanes, iii. 28; vi. 9.)

Their kings were called Chagan, or more correctly Khaghan, which was the name of the old Mongol kings a thousand years before the appearance of the Khazars. In the time of the emperor Constantinus Porphyrogenitus the Khazarian empire extended in the south to the Black Sea, and contained the northern part of the Crimea, which preserved the name of Khazaria until the thirteenth century, and the island of Taman, then inhabited by Goths; on the Caucasian isthmus it was separated from the Alans by the present river of Manytsh. The western coast of the Caspian Sea belonged to it as far as Derbent in the present country of Daghestan, where they were contiguous to the Arabs. The eastern boundaries of it were probably the river of Yaïk or Ural. On the north it extended even beyond Kasan, and on the west it was bounded by the Dniepr. In the eighth century the Khazars made the Russians of Kiew for some time tributary, as well as the Sewerians, the Radiwitshes, the Viatitshes, and other Slavonic nations. Constantinus Porphyrogenitus recommends his son to maintain an alliance with the mighty Khazars, but he severely blames his predecessor Leo, who had assumed the imperial dignity

against the will of the patriarch, and who had crowned his disobedience against the ecclesiastical authority by marrying the daughter of the Khaghan. 'For,' adds this historian, 'the Khazars, far from being orthodox Christians, are no Christians at all, but impious heathens; and Leo was punished for his crime by a carbuncle in his face, of which he died young, after severe sufferings.'* Christianity indeed, although some feeble traces of it appear in Khazaria as early as 740, was not adopted by the majority of the Khazars. On the contrary, their kings were Jews, and many Jews had founded great families in that country.

However strange this circumstance may appear, it is an undoubted fact. According to Frähn, one of the best writers on the Khazars, the religion of Moses was propagated among this people by the Jews, who were expelled from the Byzantine empire at the end of the eighth century. The princes, states Ibn Haukal, were obliged to be Jews, but the nine ministers of the Khaghan might be Jews, Christians, Mohammedans, or heathens, a fact from which we must conclude that there was great toleration in Khazaria. In the subsequent centuries we meet with some Christian princes, such as Georges Tzuda, in 1016, but the Khaghan Cosro (Khosrew), who reigned about 1140, was a Jew who had been converted to the religion of Moses by the rabbi Isaak Sangarus, as is stated by the rabbi Jehudah, in his work cited below, which is dedicated to that king.

(Ibn Haukal; Massudi, in Silvestre de Sacy, *Chrest. Arabe;* Herbelot, *Bibliothèque Orientale*, sub voce 'Khozar;' Frähn; Lehrberg, *Untersuchungen zur älteren Geschichte Russlands;* Karamsin and Bulgarin, *Hist. of Russia;* Müller, *Der Ugrische Volksstamm;* Joh. Buxtorfius, fil., *Liber Cosri*, Basileae, 1660, 4to. This last book was originally written in Arabic, by Jehudah Levita, and was translated into Hebrew by Jehudah Abn Tybbon, both Spanish rabbis.)

The Khazars were very different from those barbarous Mongol tribes which afterwards invaded Europe. Although many of them led a nomadic life, they were generally settled in villages and towns, which they embellished with magnificent buildings erected by Arabian and Byzantine architects, and the ruins of which still attest their former splendour. Ignorant historians have asserted that neither navigation nor commerce flourished among them, but there are numerous facts which prove the contrary. In the first place, the number of Jews and the toleration that existed in Khazaria may be considered as certain indications of the flourishing state of its commerce. The Khazars were renowned for their fine carpets, which were principally manufactured in their capital, Itel, the present Astrakhan, which was also called Bilándsher and Nihije, Semend, with the surname of Seraï Banu, or 'the palace of the lady,' now Tarku, Old Kasan, and Sarkel, a fortress on the Don, were also commercial towns. Honey, skins, leather, furs, fish, salt, copper of the Ural, were the goods they exchanged in the southern countries for silk, wines, spices, jewellery, which they carried to the inhabitants of the north. Gold and silver vessels, which were fabricated in India in antient times, have been found in our own days at Perm on the Kama, in the north-eastern corner of Russia. The Wolga with its tributary rivers and the Dwina were the commercial roads by which they communicated with the kingdom of Perm, the Biarmia of the old Scandinavian and Anglo-Saxon writers, and with the Norwegians, who, after having doubled North Cape, anchored in the mouth of the Dwina. This route ceased to be used when the Tatars of Kiptshak stopped all intercourse across eastern Russia, and was not re-opened before the end of the sixteenth century, when Jenkinson, an Englishman, discovered it again. Another road followed the Dniepr as far as Orkha, and, reaching the Duna in the west and the Wolkhow in the north, brought them into communication with the Baltic, and with Julin, the famous city of the Wendes. The Arabs took a considerable part in this commerce, and their presence in these northern regions is attested not only by their geographers, such as Ibn Foszlan, Massudi, Shemseddin, and Yakut, but also by numerous Kufic coins which have been found in Scandinavia, and in the vast country between the Baltic and the Black and the Caspian seas. In short, in the period from the seventh to the eleventh century, the Khazars and the Arabs followed certain commercial routes in Russia, the natural advantages of which were so obvious, that the emperor Constantinus Porphyrogenitus, overlooking entirely the tract between the upper part of the Dniepr and the sources of the Lovat, believed that the Russians of Nemogarda, the present Novgorod on the Wolkhow, sailed with their ships directly to Kiew on the Dniepr. (*De Adm. Imp.*, cap. 9.) The present canal system of Russia, which is generally regarded as the realization of an idea of Peter the Great and field-marshal Münnich, is founded on that system of commercial intercourse which had been carried into effect by the Khazars a thousand years before.

The power of the Khazars in Europe was broken by the Russians in 1016, who made their Khaghan Georges Tzula a prisoner; but in Asia it continued for two centuries longer, until it gradually sank under the repeated attacks of the Pechenegues, the Uzes, the Bulgars, the Kumanes, the Yasses, and their very name had disappeared, when, in the beginning of the thirteenth century, eastern Europe was overwhelmed by the greatest of all conquerors, Genghis Khan. (Constantinus Porphyrogenitus, *De Administrando Imperio;* Nestor; Frähn; Lehrberg; *Nova Acta Acad. Petropolitanae*, vol. iii., p. 46; *Mémoires de l'Académie de St. Pétersbourg*, vol. i., p. 527; vol. ii., p. 297; vol. iii., p. 73; vol. viii., p. 577; Hüllmann, *Geschichte des Byzantinischen Handels;* Moderach, *Déscription Economique du Gouvernement de Perm; Description of Perm*, in Hermann, *Statistische Annalen; History of the Commerce of Russia*, in Storch, *Gemälde des Russischen Reiches*, vol. iv.; Krestinin, *Geschichte der Stadt Archangel;* Lelewel, *Numismatique*, sect. 'Poland;' Hanway, *Historical Account of the British Trade over the Caspian Sea;* Hakluyt, *Navigation*, with regard to Jenkinson and Chancellor.)

Tatars of the Golden Horde, or of Kiptshak.—While Genghis Khan was carrying his arms into India and China, Batu, his grandson, invaded the west as far as the frontiers of Germany, conquered the easternmost part of Europe, which was inhabited by Slavonic, Turkish, and Finnish nations, and compelled the princes of Russia to become his vassals. One of Genghis Khan's last acts (1227) was to bestow upon Batu the dignity of a Khan or viceroy of the western conquests, which formed one of the four, and afterwards five, uluses, or under-kingdoms, into which the Mongol empire was divided. The new viceroy chose for his vast dominions the name of Kaptshak, more correctly Kiptshak, or 'the hollow tree,' which was the name of a warlike Turkish people who lived in the flat country between the Wolga and the Don, the name of which was Deshti Kiptshak, or 'the steppe of the hollow tree.' The narrower signification of this name, which still belongs to a district near the mouth of the Terek, must therefore not be confounded with its larger meaning as that of an empire the frontiers of which varied according to the military success of its inhabitants. A second name of Batu's kingdom was that of the Golden Horde, or rather, of the Golden Camp, *ordu*, the camp, having been confounded with *orda*, the horde. In his golden tent, which was at Great Seraï on the Akhtuba, a branch of the lower part of the Wolga, Batu received the Russian princes who were his vassals; Saython, king of Armenia; and Plano Carpini and Ruysbroek (Rubriquis), the ambassadors of Saint Louis, king of France, who, while fighting against the Mohammedans in Egypt as enemies of Christ, courted the friendship of heathen Tatars as useful in his schemes against Germany. Batu founded the town of Great Seraï, his capital; Seraï, called afterwards Baghji-Seraï, in the Crimea; and New Kasan at a short distance from Old Kasan. He died in 1255.

After the short reign of Sertak and Ulaghji, the eldest and the youngest sons of Batu, the throne was occupied by their paternal uncle Berke, who seized the government in spite of the right of the second and the third sons of his late brother. Berke was the first khan of Kiptshak who was converted to the Mohammedan religion, and he showed himself so zealous that he ordered all persons to be put to death who refused to follow the Korán. This happened before 1258, and thus the Islám took root on the banks of the Wolga and in the snowy deserts of Siberia. In 1260 Berke sent Noghaï, his greatest captain,

* Constantinus confounds two of his predecessors. The emperor Flavius Constantinus, a great heretic, married Irene, the daughter of the Khaghan, and died in 775; their son Flavius Leo, surnamed Chazarus, on account of his maternal origin, was a still greater heretic, and died in 780, of carbuncles in his face in his thirtieth year. (Bandurius, *Com in cap.* 13, *De Admin. Imp.*; Du Cange, *Hist. Byzant. P. I. Familiae ac Stemmata*, p. 124-126.)

against Hulaku, the Mongol governor of Persia, who aimed at independence, but was defeated on the 19th of January, 1263, in a bloody battle on the banks of the Terek, and had a considerable part of his army drowned in retreating across the frozen river. It was in the same year that Marco Polo came to the Golden Camp, where he stayed for a whole year. Berke, who is generally represented as a prince of great merit, and whose influence in Asia Minor was sensibly felt by the Byzantine emperors, died in 1266, and was succeeded by Mengku Timur, a grandson of Batu. This prince ceded to the Genoese Kaffa in the Crimea, a town which was then one of the great markets where the Tatars used to sell the immense number of prisoners that they made in Russia and Poland, as slaves to the southern nations, and especially to the Sultans of Egypt, who there recruited the body of the Mamluks. He sent commissioners into all the subject Russian towns, who sold as slaves all who did not pay the heavy poll-tax imposed upon them by the Tatars. This proceeding caused such great mischief to the commerce of Old Novgorod, that the Germans of Lübeck and other Hanseatic towns, in order to save their stores, sent ambassadors with rich presents to Mengku Timur, who reached the Golden Camp in 1269. Mengku Timur Khan died about 1283. His successors, Tuday Mengku and Talabugha, ravaged Hungary and Poland, threatened Germany, and kept up diplomatic relations with France. (Abel Rémusat, *Mémoires de l'Acad. des Inscript. et B. L.*, vol. vii.)

The following khan was Toktay, whose reign is important in many respects. Under him, paper money, an old invention, afterwards imitated in Persia, was introduced into Kiptshak under the name of Jaw, many years before any such thing was known in Europe. (J. von Klaproth, *Origin of Paper Money*; Von Hammer, p. 222.) Toktay owed his elevation to the throne to Noghaï, above mentioned, a powerful under-khan of the southern Turks of Kiptshak, who belonged to the house of Genghis Khan, and who was married to Euphrosyna, a natural daughter of the emperor Michael Palaeologus. The power and the influence of Noghaï were so great, that he would perhaps have made himself master of Kiptshak, if jealousy had not arisen among his sons and led to a civil war, in which Toktay took an active part. After a struggle of seven years, Noghaï was defeated, and died of a wound in 1295, but he left his name to his tribes, who from that time to the present day have been, and are still known under the name of Tatars Noghaïs, or Nogay Tartars. Toktay Khan, who died in the year 1313, abandoned the Islám and adored idols and the stars, but he never showed himself intolerant to other believers. He was married to a natural daughter of his ally the emperor Andronicus, who followed the policy of some other Byzantine emperors, who gave their legitimate princesses to Christian princes, while they abandoned their natural daughters to Turks and Tatars, who did not set much value on the difference between legitimate and illegitimate children.

Usbeg, the successor of Toktay, a boy thirteen years of age, found the Russian princes disobedient: they delayed to take the oath of vassalage until the young khan peremptorily ordered the first of them, Michael, grand-duke of Moscow, to appear in the Golden Camp. Michael immediately went, justified himself, and was dismissed without punishment, but Usbeg seized him some years later, and, after having punished him for some months, ordered him to be put to death. This happened (in 1319) precisely a year after the pope had written a letter to Usbeg, in which he thanked him for the kind protection that he had granted to his Christian subjects. (Mosheim, *Hist. Tutar. Eccles., Append.*, p. 130.) In 1327, the Tatarian garrison of Twer having been surprised and cut to pieces by the Russian inhabitants, who were excited to this act of national vengeance by their prince Alexander Wassiliewicz, Usbeg Khan invaded the country, slaughtered the inhabitants, expelled Alexander, and ordered John Jaroslawiez, prince of Riäsan, to be executed. Alexander also and his two sons were beheaded in 1339, and their death was preceded or followed by the execution of six princes more, among whom was Juri Danilowicz, grand-duke of Moscow. Many common people shared their fate, and for forty years after this bloody revenge, peace was never again disturbed in Russia by any rebellion against the authority of the Tatars. By a treaty of the 7th August, 1333, the first which was made between the Tatars and European states, Usbeg granted considerable commercial advantages to the Venetians of Azof or Tana. (The treaty is contained in Hammer, *Geschichte des Osmanischen Reiches*, vol. iii., p. 665.) Usbeg's court was brilliant. Although as a Mohammedan he had several wives, he was far from keeping them in that close confinement to which the women of the Oriental nations have always been subjected. Sitting on a silver throne under a golden canopy, and surrounded by his royal children and the nobles of his court, the gallant khan rose when one of his women entered the room, and stepping forwards, took the hand of the unveiled lady and led her to a seat by his side. (Hammer.) One of his daughters was married to Kusun, sultan of Egypt, a native of Kiptshak. Usbeg died in 1340, and his descendants became khans of some Turkish tribes to the east of the Caspian Sea, which are still known by the name of Usbecks.

One of Usbeg's successors, Berdibeg (1359), murdered his old father, strangled his twelve brothers, and assumed the title of 'king of the just, the sublime support of the world and of religion.' He himself was murdered three years later, and with his death the house of Batu became extinct. The reign of all the following khans was short and bloody. Civil wars shook the empire, and Kiptshak was divided for some time into several khanats, the most powerful of which were those of Kasan, of Astrakhan, of the Crimea, and of the Yaïk, each of which claimed the supremacy. At last Mamay was successful in reuniting them for a short time. He made an alliance with Jaghello, the grand-duke of Lithuania, for the purpose of subjugating the different Russian princes, who had become less dependent on Kiptshak in proportion as its strength was undermined by war and rebellion. Dmitri, the grand-duke of Moscow, had just assembled his troops, when, on the 8th of September, 1380, he was attacked in the plain of Kúlikow, by 700,000 (?) Tatars and Lithuanians. (Karamsin, v., p. 31; and all the other Russian historians.) The Tatars were defeated with dreadful slaughter; 200,000 (?) of them were left on the field, and Mamay fled to Kaffa in the Crimea, where he was treacherously murdered. For the first time during a hundred and forty years, a hope of national independence consoled the Russians.

Toktamish Khan, the son of Urus Khan, who was the founder of the dynasty of the White Horde, avenged the defeat of Kúlikow. In 1382 he took Moscow by storm, burnt the town, and ravaged Russia. He renewed the treaties with the Venetians and the Genoese, and Kiptshak was in a fair way to recover from all its calamities, when Timur, or Tamerlane, the conqueror of Asia, appeared on the banks of the Yaïk. Toktamish was twice defeated by Timur, and in a third battle on the banks of the Kama, north of the mouth of the Bielaya, which happened on the 18th of June, 1391, his whole army was slaughtered. The khan of Kiptshak, however, did not despair: he appeared in the field with a new army, and advanced to meet Timur. The encounter took place near the mouth of the Terek, on the 15th of April, 1395; but notwithstanding their heroic resistance, the Tatars were again defeated, and Timur's host overwhelmed Russia. Seraï and Astrakhan were destroyed, Moscow was threatened, and saved by the interposition of the Holy Virgin, who appeared on the walls (26th of August, 1395), and Toktamish fled to Witold, grand-duke of Lithuania. Meanwhile Timur had left Kiptshak, and his beys, unable to maintain themselves in the hostile country, were driven out in 1399 by some enterprising Tatar chiefs. One of them, Kostlogh Timur, became khan of Kasan, and the others maintained themselves in the Crimea, on the Yaïk, and at Great Seraï, the khan of which assumed the name of khan of the Golden Horde, without having much authority over the others. Encouraged by the divisions among their masters, the Russian princes paid their tribute very irregularly, and ceased to appear in the Golden Camp and to take the oath of vassalage. In 1450 Haji Ghiray was almost independent in the Crimea. From 1462 there were constant wars between the khan of Kasan and Ivan Wassiliewicz, grand-duke of Moscow, who at last conquered the whole khanat, and took the capital, Kasan, in the autumn of 1468. During this time, Casimir, king of Poland, defeated the Southern Tatars, and when the Great Khan of Seraï was bold enough to send ambassadors to Ivan to claim the

tribute which was due, the grand-duke refused it haughtily, cut off the noses of the ambassadors, and sent them back in this state to the Golden Camp. He then allied himself with Mengli, khan of the Crimea, and attacked the great khan, who was defeated, in 1480, at the Oka, and near Azof on the Don. This was the last war between Russia and the Golden Horde. Russia, free from the yoke of foreigners, was master of Kasan; Mengli became an independent khan in the Crimea, and Yaghmurji in Astrakhan. The khanat of Astrakhan was conquered by the Russians in 1544. The khanat of the Crimea, although it became a vassal state of Turkey, existed for three centuries, when it was conquered by Potemkin, under Catherine the Great. Thus the powerful kingdom of Kiptshak, the creation of Genghis Khan, became a province of Russia.

In this long struggle with the Tatars, the Russians were taught to bear chains, and to forge them for other nations. From 1240 to 1440, two hundred and fifty Russian princes went to the Golden Camp and humbly knelt before the majesty of a Tatar king; twelve of them were beheaded. One hundred and thirty noble families of Russia and many of the common people are descended from the Tatars. Many words in the Russian language, several legal customs, various social usages, and articles of dress, several names of weights, measures, and coins, ceremonies at the emperor's court, the knout itself, are of Tatar origin. The influence of the Tatars upon the Russians has never been better characterized than by that bon-mot of Napoleon: 'Scrub a Russian, and you will find a Tatar.' [Astrakhan; Casan; Crimea; Turkey; Turks.]

(Hammer, *Geschichte der Goldenen Horde in Kiptshak;* Mohammed Riza, *Asseb u's Seyiâr* (the Seven Planets); *Histoire des Khans de la Crimée*, traduite du Turk par Mirza-Kasem-Bey, 1832, in 4to.; Abulghazi; D'Ohsson Krestinin, *Geschichte der Kasanischen Zare*, Petersburg, 1791; Fischer, *Sibirische Geschichte*, Petersburg, 1768; Deguignes, *Histoire des Huns.*)

TA'RTARUS (Τάρταρος) was, according to the notions of the Greeks and Romans, a part of the lower world, and was inaccessible to the light of the sun and to the winds. Homer describes it as being as far below Hades as heaven is above the earth, and as being provided with brazen gates at its entrance. (*Iliad*, viii. 13, &c., 481.) He further regards it chiefly as the place in which the gods were punished. Hesiod entertains on the whole the same idea, but he adds that Tartarus is surrounded by a brazen wall and triple night; the roots of the earth and the sea hang down into it. It is the prison of the Titans. (Hesiod, *Theog.*, 720, &c.) In later times Tartarus designated that part of the lower world in which the shades of the wicked were punished (Plato, *De Re Publ.*, p. 616; Virgil, *Æn.*, vi. 543), and the ideas then formed of it were more awful than in earlier times. According to Virgil's description, which we may take as an example of the later ideas, the road into the lower world was divided at a certain point into two roads, the left of which led into Tartarus, which was surrounded by a triple wall and the fiery river Phlegethon, and was closed with an adamantine gate. At its outer side Tisiphone kept watch, and at the inner side the fifty-headed hydra. Rhadamanthys was the judge in Tartarus, and at his command the Furies scourged the shades of the wicked. Tartarus was twice as far below the earth as heaven above it.

Tartarus was also the name of a small river in Gallia Transpadana, which is now called Tartaro. It was connected with the Padus and Athesis by the Fossae Philistinae.

TARTARY, or more correctly TATARY. This name was in former times given by the European nations to the country of Kaptshak or Kiptshak [Tartars], or the three Khanats of Astrakhan, Kasan, and the Crimea [Astrakhan; Casan; Crimea], the last of which had the special name of Little Tatary. [Turkey.] Great Tatary, on the contrary, designated the vast country between the Caspian Sea on the west, the desert of Gobi on the east, Siberia on the north, and Persia, Afghanistan, and Tibet on the south. The greater part of it has now the more convenient name of Turkistan. [Turkistan.] The name of Tatary has entirely disappeared from geography, but it occurs frequently in the history of those regions.

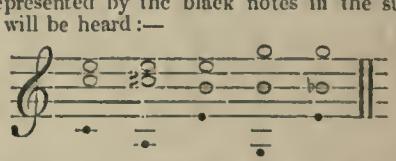
(Ritter, *Asien.*)

TARTESSUS. [Tarshish.]

TARTI'NI, GIUSEPPE, a name celebrated in the annals of music, was born at Pisano, on the coast of Istria, in 1692, and educated at the university of Padua, for the profession of jurisprudence; but his love of music triumphed over his graver pursuit, and after some struggles, and several adventures of rather a romantic kind,—among which the fighting of many duels, the marrying a cardinal's niece against her uncle's and his father's consent, and his consequent flight to a monastery, where, to avoid the effects of his eminency's resentment, he remained during two years secreted, may be thus slightly mentioned,—he became a professed violinist, and the founder of a school which in after-times boasted of a Nardini, a Pugnani, a Viotti, and a Baillot among its disciples.

Tartini was also a composer, and his productions are much extolled by a very competent judge, M. Baillot, an eminent French violinist and good critic: but he is more generally known by his writings on the art, among which his *Trattato di Musica seconda la vera Scienza dell'Armonia* (1754), a strictly scientific work, is still read, and was freely and ably translated and explained in 1771, by Edward Stillingfleet, under the title of 'Principles and Powers of Harmony,' who cleared it of many of the obscurities which D'Alembert justly complained of, and by his additions and illustrations rendered it entertaining as well as instructive. This Treatise is partly founded on the author's theory of a *Third Sound*, a subject which has so long engaged the attention of all writers on acoustics, and on which most of Tartini's work is built, that we here give an explanation of it nearly in the words of the above-named translator, or, rather, commentator.

'Two sounds being given on musical instruments that admit of the tones being held out and strengthened at pleasure, as violins, oboes, horns, &c., a third sound will be heard. On the violin let the intervals C E, C♯ E, B E, B G, B♭ G, be sounded with a strong bow, and the third sounds, represented by the black notes in the subjoined example, will be heard:—



'A similar result will occur if the same intervals be sounded by two players on the violin, distant from each other about 29 or 30 feet; always using a strong bow, and holding out the notes. The auditor will hear the third sound much better if stationed exactly between the two instruments. Two oboes will produce the same effect placed at a much greater distance.'

'This discovery of the *Grave Harmonics*, as these third sounds are called, was made so nearly at the same time by Tartini and Romieu, that both seem to have an undoubted claim to be considered as discoverers. M. Romieu was a member of the Royal Society of Sciences of Montpellier. The memoir which he read before the society is entitled "A New Discovery of Grave Harmonic Sounds, which are very sensibly produced from the union of Wind Instruments."'

Tartini died at Padua in 1770. To the *Dictionnaire des Musiciens* we are indebted for what relates to his early life: which work also furnished M. Prony with materials for an interesting memoir in the *Biographie Universelle*. In the *Encyclopédie* is an *éloge* by M. Ginguené on the compositions of Tartini, in which they are most indiscreetly compared with those of Corelli.

TARTRATES. [Tartaric Acid.]

TARUDANT. [Marocco.]

TASHKEND. [Turkistan.]

TASMAN, ABEL JANSSEN, one of the greatest navigators of the seventeenth century, whose fame has not equalled his merits, owing to his countrymen, the Dutch, having neglected to make known the important services which he rendered to geography. In the service of the Dutch East India Company he gave such proof of his enterprise and ability as to induce Anthony Van Diemen, the most distinguished governor-general who had presided over the affairs of that company, to commission him, in 1642, to proceed on a voyage, the object of which was to ascertain the extent of the Australian continent, on the western coast of which discoveries had been made by previous Dutch navigators.

On the 14th August, 1642, Tasman sailed from Batavia

in command of two vessels, the Heemskirk and the Zeehaan, directing his course first towards the Isle of France, where he put in for provisions and water. From the Isle of France he set sail on the 3rd October, and proceeded south to about 41° S. lat., afterwards to the south-east, to about 50° S. lat., and then due east. Having passed 127° E. long., he sailed to the north and east, and on the 24th November discovered, at 10 miles distance, a land to which he gave the name of Van Diemen. He did not remain here long, nor did he meet with any of the natives, but he continued on his voyage, sailing to the south-east, and doubled what he conceived to be the southern extremity of the Australian continent, or New Holland, but what in fact was the southern extremity of the island of Tasmania, or Van Diemen's Land. He made an unsuccessful attempt to anchor in a bay, to which he gave the name of the Bay of Tempests—Storm Bay—on the south-eastern coast of Van Diemen's Land; and then ran to the north, where he found secure anchorage in another bay, to which he gave the name of Frederik Hendrik Bay, 42° 52′ S. lat., 147° 57′ E. long. On the shore he erected a standard, to which he attached the colours of the Dutch East India Company, and on the 5th set sail again. Unfavourable winds prevented his surveying, as he had intended, the north coast, and he therefore bore to the east, proposing to visit the Solomon's Islands, of which some account had been given by previous navigators. But on the 13th, being in about 42° 10′ S. lat. and 170° E. long., he found himself in view of a high and mountainous country, which he named Staaten Land—land of estates—now known as New Zealand. Tasman supposed this land to be part of the continent of Australia. He sailed along the coast towards the north-east, and on the 17th anchored at the entrance of what he concluded to be a great bay. The natives from the shore approached in their canoes, but still remained at a distance, and refused to come on board either of Tasman's vessels, although every amicable demonstration was exhibited by the crews. Gathering confidence however, they afterwards came in large numbers, and a quarrel ensuing between them and the Dutch, three sailors were murdered. The bay in which this happened received the name of Mordenaars' Bay, or Murderers' Bay (40° 40′ S. lat., 173° E. long.). Tasman did not revenge the death of his men, but, availing himself of a favourable wind, set sail. Being followed however by two and twenty canoes with natives armed, he fired among them, killed one or two natives, and drove the rest on shore. He did not make any progress owing to the variableness of the weather, and was obliged to anchor again in a bay to the east of Massacre or Murderers' Bay, which yet preserves his name—Tasman's Bay (about 41° S. lat., 173° 30′ E. long.). When enabled to resume the voyage, he continued his course along the coast, bearing northwards, until, on the 4th January, 1643, he found himself in a situation in which the violence of the current bearing to the west, and the swelling of the waves, which bore to the north-west, led him to conclude that the sea in that part afforded a free passage. To the west he perceived a group of small islands which he named the Three Kings (in about 34° 3′ S. lat., 172° 5′ E. long.). Those islands were inhabited, but the violence of the waves prevented all intercourse with the natives. Tasman now resolved to sail to the east, and afterwards to the north as far as 17° S. lat., and then to the west towards the isles of Cocos (15° 50′ S. lat., 174° 10′ W. long.), and of Hoorn (14° S. lat., 178° 20′ W. long.), with a view of obtaining some fresh provisions at one of these islands. On the 6th January he saw an island to the south at three miles distance, but no name is given to it. On the 8th, being, as he represents, in 32° S. lat. and 174° E. long., the force of the waves which rolled from the south-east suggested to him that he ought not to look for land in that direction; he therefore changed his course to the north, and on the 19th discovered an island which he called Pyllstaart (22° 22′ S. lat., 176° W. long.). On the following day he saw two other islands, and on the 21st approached the more northern, which he named Amsterdam, the native name being Tonga Tahoo (21° 30′ S. lat., 175° 20′ W. long.); the other Middelburg, the native name being Eoa, the Ea-oo-wee of Cook (21° 24′ S. lat., 175° W. long.). The islanders brought various fruits in their canoes, and Tasman has described them as uniting courage with mildness. While here he discovered some other isles, before one of which he anchored, naming it Rotterdam, the native name being Ana Moka or Annamooka, 20° 15′ S. lat., 174° 31′ W. long. Captain Cook, when he visited these islands about a hundred and fifty years afterwards, found the tradition of Tasman's visit preserved among the natives.

On the 1st of February Tasman discovered the islands of Prince William, but his provisions being nearly exhausted, he could not stay to visit them. For several days subsequently the sky was so cloudy as to prevent his ascertaining the situation of his vessel, and when fine weather partially returned, he judged it best to sail towards 5° S. lat., and then to bear towards New Guinea, apprehending the return of unfavourable weather, in which he might be cast upon an unknown coast. By the 22nd of March he was in 5° 2′ S. lat., and having the advantage of clear weather and the east trade-winds, he soon came in sight of a cluster of islands which had been visited by two navigators, Schouten and Le Maire, and by them named Ontong Java. On the 29th he sailed past the Green Islands (4° 53′ S. lat., 154° 50′ E. long.), and on the 30th the Isle of St. John (3° 50′ S. lat., 153° 50′ E. long.). This island, he says, appeared to be well cultivated, to abound in flesh, fowl, fish, and fruit, and to have a numerous population. Schouten having before sustained some injury from the natives, Tasman did not attempt to land. On the 1st of April he was in sight of what he supposed to be New Guinea, but in fact of New Britain, and shortly after he doubled the cape to which Spanish navigators had before given the name of Cabo Santa Maria—Cape St. George of Dampier (5° S. lat., 152° 15′ E. long.). The crew were suddenly awoke on the night of the 12th by what resembled the shock of an earthquake: the situation of the vessel at the time, as Tasman states, being 3° 45′ S. lat. They sounded, supposing that the ship had struck, but could find no bottom. Several shocks, each less violent, succeeded. On the 20th they were near to Brandande Yland, or Burning Island, which had been mentioned before by Schouten: on the 27th they were in sight of another island, which he calls Jama, a little to the east of Moa (8° 21′ S. lat., 127° 45′ E. long.), where they obtained cocoa-nuts and other fruits. Tasman has described the inhabitants as absolutely black, and speaking a copious language, in which the frequent repetition of the letter *r* is noticed. He anchored on the following day at the Isle of Moa, where he was detained for eight days by unfavourable weather. The Dutch carried on an interchange of knives for cocoa-nuts and Indian figs with the natives. On the 12th of May he coasted the island to which Schouten had before given his name (50′ S. lat., 136° 20′ E. long.), and which is described as fertile and populous: the natives gave proof of their commerce with different Spanish vessels by the production of various articles which they had received in barter. Having now fulfilled his instructions, Tasman directed his course back to Batavia, where he arrived on the 15th June. A map of his discoveries was sent to the Stadt House at Amsterdam.

The success of this voyage induced Van Diemen to commit to Tasman the command of a second expedition, the objects of which are set forth in the instructions given by the governor-general on the occasion. These instructions are printed in the introduction to Flinders' Voyages. After quitting Point Turc, or False Cape, situated in 8° S. lat., on the south coast of New Guinea, he was to continue eastward along the coast to 9° S. lat., carefully crossing the cove at that place, looking about the high islands or Speults River with the yachts for a harbour, despatching the tender De Braak for two or three days into the cove, in order to discover whether within the great inlet there might not be found an entrance to the South Sea.* From this place he was to coast along the west coast of New Guinea (Carpentaria) to the farthest discoveries in 17° S. lat., following the coast farther, as it might run westward or southward. It was feared that he would meet in those parts with the south-east trade-winds; from

* The great inlet or cove where the passage was to be sought, is the north-west part of Torres Straits. It is evident that a suspicion was entertained in 1644 of such a strait; but that the Dutch were ignorant of its having been passed. The 'high islands' are those which lie in 10° S. lat. on the west side of the straits. Speults river appears to be the opening between the Prince of Wales Island and Cape York; through which Cook afterwards passed, and named Endeavour Strait. (Flinders' *Voyage*, 'Introduction.')

which it would be difficult to keep the coast on board, if he stretched to the south-east; but notwithstanding he was by all means to endeavour to proceed, that it might be ascertained whether the land was divided from the great known South Continent or not. These instructions were signed in 1644, 29th January, by the governor-general, and two vessels—the Zeehaan and the Bnaak—were placed at Tasman's disposal. But of the results of this second voyage absolutely nothing is known with certainty; nothing was ever published. 'It seems to have been the general opinion,' says Flinders, 'that Tasman sailed round the Gulf of Carpentaria, and then westward along Arnhem, and the northern coast of Van Diemen's Land; and the form of those coasts in Thévénot's charts of 1663, and in those of most succeeding geographers, even up to the end of the eighteenth century, is supposed to have resulted from this voyage. This opinion is strengthened by finding the names of Tasman, and of the governor-general, and of two of the council, who signed his instructions, applied to places at the head of the gulf; as is also that of Maria, the daughter of the governor, to whom Tasman is said to have been attached. In the notes also of Burgomaster Witsen, concerning the inhabitants of New Guinea and Hollandia Nova, as extracted by Mr. Dalrymple (*Collection of Voyages*), Tasman is mentioned as among those from whom his information was drawn.' Of the private life of Tasman nothing is known, neither when nor where he was born or died.

An account of Tasman's first voyage is given in the *Collection de Thévénot*, partie iv.; in Harris's *Navigantium atque Itinerantium Bibliotheca*, 1744, fol.; at the end of the *Voyages de Correa*, tome ii., Paris; in *Terra Australis Cognita, or Voyages to the Terra Australis during the Sixteenth, Seventeenth, and Eighteenth Centuries*, by Callander, Edin., 1766. From these sources, and from the *Biographie Universelle*, tome 45, the substance of this article has been collected. Tasman is not even named in Chalmers, nor in many other universal biographies in the English language.

TASMA'NIA, more generally known by the name of Van Diemen's Land, is an island and British colony situated in the southern hemisphere, south of Australia. It lies between 40° 45′ and 43° 45′ S. lat., and between 144° 45′ and 148° 30′ E. long. It is separated from Australia by Bass's Strait, which washes its northern shore. On the west of the island is the Indian Ocean, and on the east the Pacific. On the south it is washed by that portion of the ocean which connects the two first-named oceans, and extends southward to the shores of the newly-discovered antarctic continent. [South Polar Countries.] From Cape Grim, its north-western extremity, it extends south-south-east to South Cape, a distance of about 230 miles, and this is its greatest length. Its greatest width occurs near 41° 20′ S. lat., between Ordnance Point on the west and St. Helen's Point on the east, which are about 190 miles distant from one another. According to a rough estimate, the surface is 24,000 square miles, or about 4000 square miles less than the extent of Ireland.

Coast-line and Islands.—The western coast, beginning on the north at Cape Grim, and extending to South-West Cape, is about 240 miles long. It is less accessible than the other shores of the island, as in general it runs in a continuous line, being only broken by large inlets at two places. The shores are steep, exposed to the prevailing south-western winds, to a strong swell and surf, and without anchorage and shelter. This coast is therefore rarely visited by vessels, and no settlements have been established on it, except at Macquarrie Harbour and Port Davey, where a few convicts are kept to cut wood. The northern parts of this coast, and as far south as Macquarrie Harbour, are in general low, but south of Macquarrie Harbour they are high. South of Cape Grim, which consists of steep rocks of moderate elevation, the coast is formed by low black rocks, which towards West Point sink down to the level of the sea, and in this part there are a few shallow creeks. From West Point, which is formed by a short, low, and sandy projection, to the mouth of the river Arthur, the beach is low and sandy, and behind it extends a swampy level tract, covered with tea-trees to the distance of three or four miles, where the country rises into low hills. At a few places the low beach is interrupted by rocky cliffs. This low coast continues to Ordnance Point, near which is Jacob's Harbour, which is accessible to boats. At Ordnance Point the coast rises to a moderate elevation, but it is frequently interrupted by low and sandy tracts. The shores are overgrown with low bushes. A bay of moderate extent occurs between the mouth of the river Pedder and Sandy Cape, but it is shallow and useless. That part of the coast which extends from Sandy Cape to Macquarrie Harbour is almost unknown, except that it chiefly consists of sandy low shores, without a beach, at the back of which there are hills, some of which attain a considerable elevation. Macquarrie Harbour is a fine sheet of water, extending nearly 25 miles south-south-east, and terminating with two fine basins, Birch's Inlet and Kelly's Basin. It is on an average five miles wide, and affords good anchorage and complete shelter; but near its entrance is a bar, which has only nine feet of water. The harbour is surrounded by wooded hills. Cape Sorell, forming the western side of the entrance of Macquarrie Harbour, is a steep and rocky promontory, and farther south the coast-line is high and rocky, and here and there a few rocks project into the sea, but the small bays thus formed do not afford shelter against the swell of the sea, and not even a safe landing-place. At the back of the beach there are steep and lofty hills. Cape Hibbs is formed by a mountain-mass projecting three or four miles into the sea. South of it the coast rises still higher, and between that cape and Rocky Point two hills, which project about two miles from the shores, constitute a harbour, in which small vessels may anchor, but it is open to the west. The high shores continue to Port Davey and to South-West Cape. Port Davey is the best harbour on this coast. At the entrance it is about four miles wide, and it continues at that width about 6 miles inland, when it divides into two branches. That branch which runs northward is called Cockburn, and is about two miles wide and six long: the southern, which runs eastward, does not much exceed a mile in width, but extends more than 10 miles inland, turning at its eastern extremity to the south. These two branches have good anchorage, and afford safe shelter, being surrounded by high hills; but the wide bay, of which they are branches, is open to the westerly winds and the swell of the sea: the anchorage however is good.

The southern coast, between South-West Cape and Whale Head, is about 50 miles long, and runs in a serpentine line, forming several bays, of which a few have good anchorage, as Cox Bight, east of South-West Cape, and the nameless wide bay which lies west of South Cape, and at whose innermost recess is a harbour about five miles long and a mile wide, which has a good entrance, and affords anchorage and shelter, but it has not been regularly surveyed. This harbour is separated from the wide bay by a tongue of land of moderate elevation, on which the sea breaks with a heavy surf. The shores of this coast are in general rocky and high, and constitute the lower declivity of the mountain-masses which extend over this part of the country. Several small islands opposite this coast break the swell of the sea, and as most of them are elevated, they serve as beacons.

The south-eastern coast extends from Whale Head, the most south-eastern promontory of Tasmania, to Cape Frederik Hendrik, about 60 miles in a straight line, but, measured along the shores, it is probably double that extent. It contains a greater number of safe anchorages than probably any other country of the same extent on the globe. There is hardly a mile along this coast-line which does not offer a safe refuge to vessels. This great advantage is owing partly to the size and form of the island of Bruni, which extends along the coast, and partly to two far-projecting promontories, called Ralph's Peninsula and Tasman's Peninsula. The island of Bruni extends about 30 miles nearly due south and north, but it varies greatly in width, as the isthmus of St. Algnan is only a few hundred paces across, whilst the mountain tract south of it is more than eight miles wide. It consists of three isolated tracts of high hills, connected by isthmuses: the most southern of these tracts has the form of a hook, and is connected with the central mountain-tract by a low isthmus about a mile wide and two miles long, which separates Taylor's Bay from Bad Bay. The central mountain-tract, constituting the main body of the island, is about 15 miles long from south to north, and more than eight miles wide in the broadest part. It is connected with the northern mountain-tract by the isthmus of

St. Aignan, which is five miles long, and only a few hundred paces wide. It is low and sandy, and separates Isthmus Bay on the west from Adventure Bay on the east. The northern mountain-tract is about 12 miles long, and so much indented on the western shore that its average width does not exceed three miles, though in some places it is five miles across. The mountains of this island do not appear to exceed 1200 feet in elevation: they are covered with wood, and supply numerous streams. Along the western side of the island are five harbours, which, from south to north, are called Great Cove or Taylor's Bay, Little Cove, Isthmus Bay, Great Bay, and Burnes Bay. They all have excellent anchorage and shelter, except Taylor's Bay, which is rather too large, and exposed to the gusts of wind which come down from the mountains on the mainland. On the eastern side of Bruni Island are three bays, Bad Bay, Adventure Bay, and Trumpeter Bay. Bad Bay is useless, being open to the southern winds, and subject to a very heavy swell, which causes such a tremendous surf at the foot of the rocks which surround the basin, that landing is almost impossible. Adventure Bay is open to the east, but is so far protected by Tasman's Peninsula, that the inconveniences of this harbour during easterly winds are reduced to a difficult landing. Before the foundation of the colony it was frequently visited by whalers. Trumpeter Bay is of moderate extent.

The strait which divides Bruni Island from the mainland of Tasmania is called D'Entrecasteaux Channel, or Storm Bay Passage, and extends 45 miles in a straight line from Whale Head to Pilot Strait, or the narrow arm that divides the northern extremity of Bruni Island from Tasmania. Its southern entrance between Whale Head and Bruni Head is wide and open to the south and west; but on the western shores there are two excellent harbours, Recherche Bay and Mussel Bay. North of Mussel Bay the channel begins, which is 30 miles long, and varies in width from one to eight miles. In all its extent it has excellent anchorage and sufficient depth; even opposite Isthmus Bay, where it is shallowest, it is 40 feet deep. Being mostly surrounded by hills, which shelter it on all sides, it is, properly speaking, an immense harbour, the only inconveniences of which are that it is subject to gusts of wind, and that the bottom consists of an earth somewhat too tenacious. On the western shores of the channel, besides several smaller harbours or coves, there are three, or rather four, large and excellent ports: Esperance Bay or Adamson's Harbour; Huon Bay, or the extensive æstuary of the river of that name, which extends nearly 20 miles inland, and has sufficient depth of water for large vessels; Port Cygnet, or Swan Port, situated near the mouth of the Huon æstuary; and North-West Bay, which constitutes the most northern extremity of D'Entreeasteaux Channel, and resembles the harbour of Portsmouth. North-West Bay is two miles wide at its entrance, and extends nearly six miles inland. The low and level country surrounding this excellent basin is the most southern district of Tasmania in which cultivation has made any progress. The strait leading from it to the wide æstuary of the river Derwent is only one mile wide, and is called Pilot Strait.

East of Bruni Island, and between it and Tasman's Peninsula is Storm Bay, extending about fifteen miles from south to north, and as much from west to east. Though it has good anchorage-ground, and is almost entirely free from danger, it cannot be considered as a harbour, being open towards the south, though protected on the three other sides by high hills. Storm Bay however leads to two extensive arms of the sea, which open to the north of it, and are respectively called the æstuary of the Derwent and Frederick Henry Bay. These two arms of the sea are separated by Ralph's Peninsula, which extends about 20 miles from north to south; and this distance may be considered as the length of the two arms of the sea, the æstuary of the Derwent advancing a few miles farther inland. At the entrance of the æstuary is a small rocky island, Ironpot, on which a lighthouse has been erected. Within the æstuary is Ralph's Bay, on the east. This bay is formed by a low sandy spit of land which projects from the west side of Ralph's Peninsula, and surrounds the bay on the south and west; and by another spit of land which projects to the south. The entrance of Ralph's Bay is a short channel, nearly two miles wide, which leads to a basin eight miles long and three wide, with excellent anchorage, and sheltered on all sides. Ralph's Peninsula consists of two mountainous tracts united by a low isthmus. This isthmus is only half a mile wide, and is the place where Ralph's Bay approaches nearest to Frederick Henry Bay. This last-mentioned bay, which has also the name of North Bay (Bai du Nord) is united to Storm Bay by a channel situated between Ralph's Peninsula and Tasman's Peninsula, which is five miles long and five miles wide. The bay itself consists of three basins, North Bay, Pitt Water, and Norfolk Bay. North Bay, which occupies the centre, is a basin about eight miles long from south to north, and six from west to east. It has good anchorage, with sufficient depth of water, and is generally well sheltered. Along its northern shores there is a low and sandy tongue of land, with an opening at its eastern extremity, which leads to Pitt Water, an arm of the sea extending from east-south-east to west-north-west about eight miles, with an average width of two miles, which branches out into numerous small coves and inlets affording safe anchorage for small vessels, but the entrance has only sufficient depth for them. Norfolk Bay lies to the east of North Bay, with which it is connected by a channel about three miles wide. This bay is surrounded on three sides by Tasman's Peninsula, and constitutes one of the finest harbours on the island: it has excellent anchorage, with a convenient depth of water, and is sheltered by high hills. It is eight miles long, and the width varies from three to five miles. It is free from all danger, and branches out into numerous coves.

Tasman's Peninsula extends about 25 miles from south to north: it consists of two larger peninsulas, of which the southern is properly called Tasman's, and the northern Forestier's Peninsula. Tasman's Peninsula surrounds Norfolk Bay on the south and west: it extends west and east about 15 miles, with an average width of eight miles. The surface of this tract is covered with mountains, which rise with a steep ascent from the water's edge, and are mostly composed of basalt columns, especially between Maingon Bay and Fortesque Bay. On the west side of the peninsula, on the east shores of Storm Bay, is Wedge Bay, which has tolerably good anchorage. Maingon Bay, on the south coast of the peninsula, is quite open, but on the north it leads into a safe harbour, Port Arthur, which runs more than six miles inland, and is more than a mile wide. The high rocky isthmus which divides its northern extremity from Norfolk Bay is only three miles wide. On the eastern shores of Tasman's Peninsula is Fortesque Bay, which is large, and has excellent anchorage, but it is open to the east. Pirates Bay, farther north, is still more open: it is separated from Norfolk Bay by an isthmus called Eagle Hawk Neck, which is only 600 feet wide and 700 feet long, and which connects Tasman's Peninsula with Forestier's Peninsula. It is low and sandy. Forestier's Peninsula extends 10 miles from south to north, with an average width of seven miles: it is a roundish mass of high rocky mountains, scantily covered with low trees, and it has a sterile soil. The high rocky masses along its eastern shores run in a continuous line. On the north side of the peninsula is Frederik Hendrik Harbour, in which Tasman anchored in 1642: it has good depth, but is open, and along the southern side it is lined with shoals and rocks. The isthmus which joins Forestier's Peninsula to the mainland of Tasmania is called East Bay Neck, and the northern portion of Norfolk Bay is also known by the name of East Bay: it is about two miles long, and half a mile wide in the narrowest part: it is low and sandy. The bay which extends between this neck and the most northern portion of Forestier's Peninsula, and is called Blackman's Bay, is spacious and well sheltered, but beset with shoals and rocks, especially along the southern shores and its entrance, so as to admit only small vessels.

The eastern coast of Tasmania extends from the northern extremity of Forestier's Peninsula to Cape Portland on Bass's Strait, more than 150 miles in a straight line. The southern part, or that south of 42° S. lat., resembles in some degree the south-eastern coast: it contains many places of refuge for vessels, though in general they are much less numerous than on the south-east coast, and not quite so safe and commodious. The wide bay on the north of Forestier's Peninsula, from which a channel leads to Blackman's Bay, has a flat sandy shore, no which the sea breaks with a heavy surf, so as to render it inaccessible, but towards the north are several small coves for boats. Cape Bernier is formed by a high conical hill: between it and

Prosser's Bay the coast is high and rocky, except at Sand-spit, where it is low, and forms a shallow cove. Prosser's Bay is of good size, being three miles wide at its entrance, and extending in two arms five miles inland. There are several shoals in it, but it has good anchorage, especially in the northern arm. Between Prosser's Bay and Cape Bailly the coast is high, rocky, and well wooded. At Cape Bailly begins Oyster Bay, the largest of the bays of Tasmania: it is 18 miles long from south to north, and 15 miles wide at the entrance, but it narrows gradually towards the north, being at its northern recess 10 miles across. It contains good anchoring-ground, and is tolerably safe, for though it is open towards the south, the island of Maria and several smaller islands in that direction break the swell of the sea. The surrounding country is hilly and well wooded. Near Cape Bailly is Little Swan Port, a moderately extensive basin with a shallow entrance. It admits only boats. The western shores of Oyster Bay are high and steep, and may be approached with safety. On the northern side of the bay is a tongue of land less than a mile wide. It consists of low sand-hills, and terminates on the east at a narrow and shallow channel, which leads northward to an arm of the sea, which winds through a low country for more than 10 miles. This arm of the sea is shallow, and called Moulting Lagoon. The eastern side of Oyster Bay is formed by Vanderlin's Peninsula and Schouten's Island. Vanderlin's Peninsula is nearly 12 miles long, and consists of two masses of rocky mountains, united by a low sandy neck, about one mile and a half long and one mile and a half wide, on which is a small fresh-water lake. To the west of this neck is Refuge Bay, and to the east Thouin Bay. The first is a safe harbour, but the second is open and rather shallow. Another low and sandy neck about three miles long and a mile wide connects Vanderlin's Peninsula with the main body of Tasmania. The mountains of the southern mass of Vanderlin's Peninsula are the highest in the peninsula. Schouten's Island is separated from that peninsula by Geographe Strait, which is nearly three miles long and about one mile and a half wide on an average: there is good anchorage in the strait. Schouten's Island has nearly the form of a square, and extends about four miles in every direction. On its southern side, in Faure Bay, there is anchoring-ground. The island consists of a mass of rock, descending on the east with a steep declivity to the water's edge, but on the west with a gentle well-wooded slope.

South of Oyster Bay is the island of Maria, which is about 12 miles long, and consists of two large masses of rocks connected by a neck of land. The northern mass extends 7 miles from east to west, and consists of elevated mountains, the highest part of which, called the Bishop and Clerk, is about 3500 feet above the sea-level. The declivity of the mountains towards the east is very steep and terminates on the beach; but the slope is gentle towards the west, where it leaves a broad level tract along the sea, which is sandy and scantily wooded. The low sandy neck south of it is only 300 paces across, and about two miles long. On the west of it is Oyster Bay, which is well sheltered and has good anchorage, but is shallow near the land; and on the east of the neck is Reidle Bay, which is deeper, but has a rocky bottom, and is exposed to the easterly and southerly winds. The southern peninsula of Maria Island is one mass of rocks, rather well wooded, which descends towards the east in precipices and towards the west with a gentle slope. The strait which divides Maria Island from the mainland is about five miles wide on an average, and is nearly equal to D'Entrecasteaux Channel in the advantages which it affords to navigation, having good anchorage-ground, and being generally well protected against the winds and swell of the sea. North of Maria Island, towards the entrance of Oyster Bay, is a small island, White Rock, to which seals resort in great numbers.

The remainder of the eastern coast, beginning at Cape Tourville on the south, is as difficult of access as the western coast of Tasmania. In an extent of more than 100 miles not one harbour occurs which can be entered by vessels of moderate size, and even small craft find only three or four places where they can anchor with safety. The coast between Cape Tourville and Eddystone Point is elevated and rocky, and always beaten by a heavy surf. South of Cape Lodi the hills are barren and generally destitute of trees. Farther north however they are still more elevated, but tolerably well wooded. Between Eddystone Point and Cape Portland the shores consist of a low tract of considerable width: the soil is sandy and of indifferent fertility. The woods which cover it consist of short, crooked trees. This part of the coast is beset with shoals, and cannot be approached with safety.

The northern coast of Tasmania extends from Cape Portland on the east to Cape Grim on the west, and is about 160 miles long in a straight line, but following the coast it measures more than 220 miles. North of this coast is Bass's Strait, at the eastern entrance of which is the group of the Furneaux Islands, which consist of two larger islands, four of moderate size, and many smaller islands. The larger, Great Island, extends 40 miles nearly due south and north, and is on an average nine miles long, so that its surface may be estimated at 360 square miles, or somewhat more than that of the Scotch island of Islay. The interior of the island is mountainous, and the mountains advance on the west side close to the sea, but leave a tract of low ground along the eastern shore, which is sandy and in some parts swampy. South of Great Island is Cape Barren Island, which extends from east to west about 20 miles, with an average width of about five miles. It consists of several isolated masses of rocks connected by low grounds. These islands, as well as the smaller islands, are generally mountainous and rather high; they contain many low tracts of considerable extent, but the soil is sandy, swampy, and in general of indifferent quality. Trees are not abundant, and only of stunted growth. The surface is chiefly covered with thick bushes, coarse wire-grass, and a kind of Chenopodium, the ashes of which may be used in the manufacture of soap. Fresh water is scarce. These islands are always surrounded by great numbers of seals, and are resorted to by many vessels from Sydney and other places. The strait which divides Furneaux Islands from Tasmania is called Banks's Strait. It is 10 miles wide, and contains no hidden dangers, but as the current sets through it with great rapidity from east to west, it is not much used: the vessels that sail to and from Sidney generally pass through Kent Strait, or the middle strait of the three which constitute the eastern entrance of Bass's Strait. This strait is 24 miles wide between Great Island and Kent Group, and in general free from dangers. The western current which runs through it is moderate.

The coast from Cape Portland on the east to Port Dalrymple at the mouth of the river Tamar is low and sandy, with the exception of some sandy hills at and between East and West Double Sandy Points, and the high cape of Stony Head, which consists of elevated rocky masses overgrown with grass. The shores are either entirely barren or covered with short bushes. In a few places there are swamps, and in others some flat and low rocks of small extent. The bays have in general sufficient depth of water and good anchorage-ground, but being wide and open, they do not afford security against winds and the swell of the sea. The largest is Ringarooma Bay, west of Cape Portland.

Port Dalrymple is the best harbour on the northern shores, though it cannot be compared with the harbours on the south-eastern coast. Before its entrance on the west is the dangerous reef called Hebes Reef, and even in the sea-reach, which is two miles wide and six long, there are some shoals. The navigation is tedious and difficult, but the Tamar is deep enough for large vessels as far as Launceston, 30 miles from Port Dalrymple in a straight line. West of Port Dalrymple the coast is high, being formed by elevated and wooded hills, the highest of which are called the Asbestos Hills. To the west of these hills is Port Sorell, which is rather spacious and has good anchorage, but is difficult of access. Between Port Sorell and Port Frederick the shores are low, and about half a mile from the sea is a narrow lagoon, which occupies more than half of the space between the two harbours. Port Frederick, or the estuary of the river Mersey, resembles Port Sorell. From this harbour to Penguin Point, west of the mouth of Leven river, the coast is generally rocky and high, but intersected by the mouths of several rivers, which however do not admit even boats, except the Leven, which may be ascended by boats to the distance of six miles from the sea. From Penguin Point to Circular Head the coast presents an alternation of high and low shores. The low shores are sandy or swampy, and generally covered with

thick busnes, and the high shores present in many places columns of basalt, the tops of which are covered with a layer of good soil, and overgrown with trees. There is no harbour for ships on the coast, except at the mouth of Emu river, where small vessels find good anchorage in Emu Bay. Boats may enter Parish's Harbour, not far from Emu Bay to the west, and Pebbly Bay, west of Rocky Cape, a rather elevated rocky mass projecting into the sea.

Circular Head is a tongue of land projecting into the sea to the distance of about seven miles from the mainland. Its northern portion is an undulating table-land resting on basalt columns, whose surface is covered with bushes and small trees, and affords good pasture-ground. The highest part of it is 450 feet above the sea-level. This table-land is about five miles long from north to south, and somewhat more than two miles across in the widest part. It is united to the mainland by a low sandy isthmus nearly three miles long and about one mile wide. On each side of the isthmus is a tongue of land, which advances four or five miles into the sea, and forms two harbours, called East and West Bay, which have sufficient depth for small vessels. The advantages afforded by these two harbours, and the pasture-ground on Circular Head, have induced the Van Diemen's Land Company to fix their chief establishment here. The coast from Circular Head to Cape Grim is low and sandy. In some places there are swamps overgrown with tea-trees. It is lined by numerous shoals, and though there are several coves at the embouchures of the rivers, none of them has sufficient depth of water for a boat.

North of this coast-line are the Hunter Islands, a group consisting of three larger and several smaller islands. Robbin Island, the nearest to the mainland, is divided from it by a narrow strait, Robbin Channel, which is full of shoals, but has good anchoring-ground near the eastern entrance. The island is about 7 miles long from east to west, and 5 miles wide on an average. The eastern portion, embracing about two-thirds of the whole, is low, and has a sandy soil, covered with bushes and small trees: it has also pasture-ground. The western district is a rocky ridge, covered with heath. Three-Hummock Island is about the same size, but it is hilly, and chiefly covered with bushes, low trees, or grass. On its eastern side is a cove, with indifferent anchorage. West of Three-Hummock Island is Barren Island, which is the largest of the group, being 15 miles long, and on an average 4 miles wide. It is likewise rocky in its whole extent, but less elevated than Three-Hummock Island: in fertility it seems to resemble it very much. On the western shores are numerous reefs, which render the access to the island difficult and almost impossible. Towards the southern end of that coast however there is a cove, which is accessible to boats. The strait between Barren Island and Three-Hummock is called Peron Channel: it is well protected by the surrounding islands, and has good anchorage at several places, so that it may be considered the best harbour at the western entrance of Bass Strait. The basin, surrounded by the three large islands of this group, is called Boulanger Bay. It is well protected, but very dangerous, being full of shoals and small low islands, especially towards the north-western district of Tasmania.

Surface and Soil.—As the first European settlement on Tasmania was established only forty years ago, it can be no matter of surprise that the country is imperfectly explored. Nearly one-half of the island is almost unknown, namely, nearly two-thirds of that portion which is south of 42°, and one-third of that which is north of that parallel.

The *Unexplored Mountain-Region*, south of 42°, occupies the southern and western districts of the island, and reaches north-east to the banks of the river Derwent. This river, from its source in Lake St. Clair to its mouth, separates the well-known part of the island from that which is entirely unknown except the coasts and the districts in the immediate vicinity of the river. These districts are occupied by an apparently continuous mountain-range, which extends along the river at a short distance from its banks, and in some places sends off branches which advance close to the river. This range is sometimes called the Western Mountains by the settlers, but has not yet obtained any other name. It begins on the æstuary of the Derwent, opposite the entrance of Ralph's Bay, with Mount Nelson, which is considered to be about 1000 feet above the sea. Hence it extends north-west to Mount Wellington, which is a few miles west of Hobart Town, and rises, according to Darwin, 3100 feet above the sea. Farther on, the range, which occupies a width of perhaps 20 miles, does not seem to contain many summits which rise much above the general level of the range, which level probably is never less than 2000 feet above the sea. The summits, which have been noticed, are—Mount Field (near 42° 40′), which is estimated at 3000 feet; and Wyld's Craig, or Peak of Teneriffe, about 4500 feet above the sea. The latter is covered with snow for nine months. It is stated that in several places plains of considerable extent occur on the top of the range; but as the whole of it is covered with an impenetrable forest, it has hitherto been impossible to ascertain this fact. The mountains which surround Lake St. Clair, the source of the river Derwent, appear to be connected with this range, and to constitute its northern extremity. At the southern extremity of the range is a large peninsula, formed by D'Entrecasteaux Channel and the æstuary of the river Huon, the whole of which is covered with high hills, clothed with dense forests to their summits, and broken only in a few places by valleys, which exhibit a great degree of fertility, but in which no settlements have yet been made.

The remainder of this region is only known so far as it has been observed from the sea and a few places from the coast. The most striking feature of this district is a mountain-range which rises a few miles from the southern coast, and appears to extend, without interruption, from the eastern part of Port Davey, called Bathurst Harbour, to the vicinity of Port Refuge, at the entrance of D'Entrecasteaux Channel. Its lower parts are covered with thick forests, but the higher are without wood. Some parts of them appear white, which has suggested the opinion that they are always covered with snow; but this fact is questioned. The higher parts however are considered to rise to an elevation of 5000 feet above the sea-level. North of this range there are two elevated mountain-masses, a few miles south of 43° S. lat., which are called Harz Mountain and Arthur's Range. The latter is visible from Mount Wellington, though more than 50 miles distant. At the back of these masses, north of 43° S. lat., open plains are stated to extend from the banks of the river Huon to the mountains which line the western shores. A few open plains of moderate extent are also found near the banks of the Huon, where the river runs eastward; but farther down the whole country is covered with impenetrable forests. From this river to 42° S. lat. the country is entirely unknown. Several summits have been seen from considerable distances. The most elevated appears to be Frenchman's Cap, east of Macquarrie Harbour, which is covered with snow nearly the whole year: its base is said to be surrounded by woodless, open, and grassy plains of considerable extent. The forests, which cover this region almost without interruption, consist chiefly of different kinds of Eucalyptus, especially Eucalyptus globulus, and different kinds of pines, among which Tasmania and many tree-like ferns are frequently met with.

The *Valley of the Lower Derwent* extends from Mount Nelson upwards to the confluence of the Derwent with the Ouse (near 42° 35′ S. lat.), and is rather more than 50 miles long, measured along the bends of the river. The Derwent runs close to the range of high mountains which extend along its western banks; and the space between the banks of the river and the base of the steep rocky masses hardly ever exceeds a mile in width, and is frequently not half so much. The soil of this narrow and comparatively level tract is of great fertility, and a large part of it is under cultivation. On the east of the river the valley extends to the distance of about five miles, where it meets the higher hills that enclose the valleys which lie farther east and north. The surface of this part of the valley is level near the banks of the river, and subject to inundations; but at a short distance from them the ground rises in gentle undulations, on which some low and isolated hills are met with. The soil of this tract appears to be generally of first-rate quality: it produces rich crops of wheat, and is well adapted to orchards. Cultivation is rapidly spreading over this tract.

A *Hilly Region* extends east of the Lower Valley of the Derwent. It extends eastward to the shores of the Pacific, and northward nearly to 42° 35′ S. lat. The surface of this tract is a continuous succession of hill and dale. The tra-

veller no sooner arrives at the bottom of one hill than he has to ascend another, often three or four times in the space of a mile. In some places the land swells into greater heights, which have several miles of ascent. Except the valleys, which constitute the bottoms of the numerous rivers which traverse this region from north to south, and which are generally of moderate width, the level tracts, either marshes or plains, are comparatively few. The most elevated part of this region appears to be a ridge of high ground which begins on the north at Table Mountain, a summit standing near the south-eastern extremity of Lake Sorell, whose elevation is estimated at 3800 feet. The ridge branching off from it towards the south is of moderate elevation, but considerable width, occupying the greater part of the tract between the rivers Clyde and Jordan. It terminates about five miles from the banks of the Derwent in Mount Dromedary, the summit of which is 1800 feet above the sea-level. In general the hills sink lower as we proceed south, and the surface of Ralph's Peninsula, and of the country enclosing Pitt's Water and North Bay, is only undulating. Cultivation in this region is almost exclusively limited to the bottoms of the rivers, where there is a strong soil, which produces plentiful crops of wheat and other grain. The declivity of the hills is sometimes too steep for cultivation, and they are generally covered with thick woods. But even where the declivities are gentle, which is most frequently the case, the soil is too dry. These declivities, and also the upper parts of the hills, where small levels frequently occur, are overgrown with open forests without underwood, under the shade of which there is grass nearly all the year round. These hills afford excellent pasture for sheep and cattle. This description applies to the whole region, except that portion which is north of Norfolk Bay, and which appears not to have been explored. That part of it which lies along the Pacific consists only of rocky masses, frequently destitute of woods and bushes, and in other places overgrown with crooked and stunted trees.

The *Elevated Plains* are north of the Hilly Region, and extend from 42° 35′ to about 41° 50′. They are separated from the Pacific by a higher tract, called Eastern Tier. This tract begins on the south near 42° 35′, where it is about 10 miles wide, and extends northward to the valley of the South Esk, to which it descends with a steep declivity. It increases in width as it proceeds farther north, and on the banks of the South Esk it is more than 30 miles from east to west. This region also is entirely unknown, and is a blank on our maps. We can find no information respecting its character and capabilities. The heights which extend along the sea are very scantily wooded, and do not present a promising aspect. The plains themselves are divided into the southern and northern plains by a somewhat hilly and wooded tract, which crosses them in a diagonal direction from south-east to north-west, beginning on the Eastern Tier with the Blue Hills, south-east of Oatlands, and passing east of that township to Table Mount, and the other heights surrounding Lake Sorell, and hence to the range of mountains called the Western Tier or Western Mountains, from the southern extremity of which it is divided by the upper valley of Lake River. Farther west the Western Tier constitutes the northern boundary of the southern plains. These southern plains are distinguished by many large lakes. The most western of these lakes is that of St. Clair, the source of the Derwent river. It is about ten miles long and three miles wide on an average, and differs from the lakes farther east in having more of the shape of an alpine lake and being surrounded by mountains. The country east of the lake St. Clair is not included in the plains, being very mountainous, and containing several high summits between the Derwent on the west and the Nive river on the east. Even to the east of the last-mentioned river that part of the country which lies near the Derwent is extremely uneven and hilly, but farther north the southern plains begin with the tract that surrounds Lake Echo. This lake is of a round form, but only three miles in diameter. The shape of this, like all those farther east, shows that they are not enclosed by mountains, but spread out in plains. North of Lake Echo is Great Lake, the source of the Shannon, one of the largest tributaries of the Derwent. It is said that this lake is 20 miles long, 10 wide, and, owing to its numerous branches, 75 miles in circuit; but our maps give it hardly half these dimensions. East of Great Lake are the three Arthur lakes, the largest of which has a circuit of between 20 and 30 miles. Lake Sorell, which is farther to the south-east, is of a very irregular form, and hardly inferior in extent to Great Lake. Smaller lakes are numerous, especially along the wooded tract which separates the southern from the northern plains. There are fewer lakes in the northern plains, and they are all small, with the exception of the Western Lagoon, a cluster of lakes situated at the eastern termination of the Western Tier, the largest of which may be five miles long and half a mile wide. The woody tract separating the plains has a hilly surface, and is about eight miles wide where it is crossed by the great road from Hobart Town to Launceston. In the plains there are some short ridges of low hills, which rise above the common level with very long slopes, and are covered with open forests. At other places there are single hills, mostly of a conical form, hence called sugar-loaves: they are most frequent in the district which approaches the Eastern Tier. In other respects the surface of the plains is either a dead level or slightly undulating. In their natural state they are generally destitute of trees, but in a few spots, especially where the surface is undulating, trees occur in small clumps. The climate is much colder than in the low tracts near the coast, as the snow sometimes covers the ground for several weeks, and thus the soil imbibes sufficient moisture to maintain a vigorous growth of grass nearly all the year round. The pastures thus produced constitute the agricultural wealth of this region, as the soil is seldom rich enough for the growth of grain. The pastures are much better adapted for sheep than for cattle, and the chief part of the wool exported from Tasmania is brought to the seaports from this region. Among these plains that called Salt-Pan Plain requires notice. It lies near the watershed of the Derwent and Tamar, between the sources of the Macquarrie river, which runs to the Tamar, and those of the Jordan, which falls into the Derwent. In this plain are three ponds, or, rather, hollow depressions, which are filled with water during the rainy season, but dry up when the rains are over, and the soil is then so strongly impregnated with salt that a considerable quantity is collected every season for domestic purposes.

The region hitherto described is watered by many streams, most of which join the Derwent. This river originates, as already observed, in Lake St. Clair. It runs about 60 miles measured in a straight line, until it meets the tide-water, and its general course is south-east. Issuing from the lake, it traverses for several miles a plain, and then enters a narrow valley bounded by mountains, in which it is joined from the north by the Nive, and from the south by the Florentine river, the course of which two tributaries is hardly known. It leaves the mountains above its junction with the Dee, where it forms two cataracts, a mile from one another, of which the uppermost is 30 feet high. It then flows along the foot of the western mountains with a rapid current, and is not navigated, chiefly owing to the numerous rocks along its banks, but also partly because its volume of water is subject to great changes. The last rapids occur at New Norfolk, up to which place the tide-water comes. During the summer months the water of the river is brackish, and unfit for drinking at New Norfolk; but when it is swollen by rains, it is fresh to the distance of two or three miles below the town. The river is here a quarter of a mile wide, and begins to be navigable for ships. A few miles lower down the river widens to three-quarters of a mile, which width is gradually increased to two miles. Below Hobart Town it varies between two and four miles, and is deep enough for large vessels, and free from shoals, which are rather numerous above that town. The tide ascends 30 miles from Storm Bay. None of the tributaries which enter the Derwent from the south, after it has emerged from the mountains, are above the size of a mountain-torrent; but it receives several rivers from the north which flow from 20 to 30 miles, as the Dee, the Ouse, the Clyde, and the Jordan. Some of them form cataracts and rapids, and none of them are navigable.

The river Huon, which drains the greater part of the mountain-region west of the Derwent, has a course of about 80 miles; but this river lies without the settled portion of the colony, and its course has only been explored within a few years. No account of it exists. It forms a wide æstuary, like the Derwent, which opens in D'Entrecasteaux Bay. Coal River drains the undulating country east of

the Derwent, and falls into Pitt's Water: its course is about 20 miles.

We pass to the description of the northern part of Tasmania (north of 41° 50′). The watershed of the eastern districts of this country lies close to the Pacific, as the remotest sources of the South Esk are only from four to five miles from its shores. The Upper Valley of the South Esk lies between two large mountain-masses, but the Lower Valley constitutes a part of the Basin of Lincoln. The Upper Valley extends from the sources of the river westward to the vicinity of Ben Lomond Rivulet, where an offset of the Ben Lomond comes close to the river, whilst from the south the most north-western branch of the Eastern Tier also approaches very near, so that there is a natural pass by which the Upper Valley of the South Esk is entered. This valley extends about 35 miles from the gorge, following the St. Paul's River, but nearly 50 miles along the Break-o'-Day River. The mountains which extend along the shores of the Pacific, and connect the northern part of the Eastern Tier with the range of the Ben Lomond, have not been explored. When seen from the sea they constitute a high range, overtopped by several summits, among which is Tasman's Peak and Mount Champagny, south-west of Cape St. Helen's: the last mentioned, a conical summit, rises about 3000 feet above the sea. It has not yet been ascertained where and how this maritime range is connected with Ben Lomond. Ben Lomond appears to be the highest ground in this part of Tasmania, and is estimated to rise 4200 feet, or about 1200 feet higher than the mountain in Scotland whose name has been transferred to it. The mountain-mass, of which it forms the most elevated portion, extends to a considerable distance to the south-west, where, as already observed, it comes close to the banks of the South Esk, near the place where it is joined by Ben Lomond Rivulet, and it is probable that it advances still farther to the north-east, in which direction this region has not been explored. It is however certain that the maritime range and that of Ben Lomond join at an acute angle, leaving between them a depression of a basin-like shape, which may be called the Basin of Fingal, from a township of that name situated near the place where the South Esk and the Break-o'-Day River join. The existence of this basin has only been ascertained within the last ten years, and our information respecting it is scanty; but as the settlements begin to be numerous, and as it has been divided into hundreds, we may presume that the soil of this tract is good. The Basin of Fingal extends from north to south about 15 miles, and about as much from east to west. Its southern districts are drained by the Break-o'-Day River, which rises in the maritime range, and, running eastward, meets below Fingal the South Esk, which originates in the Ben Lomond range, and waters the northern districts of the basin. A few miles below the confluence of these two branches, the South Esk, having a south-west course, enters a wide valley, about 10 miles long, and afterwards reaches a plain, where it is met by the St. Paul's River. The valley, through which the last-mentioned branch of the South Esk descends from its source in the maritime range, is for a considerable part of its course so wide, that it has obtained the name of St. Paul's Plains, which are described as an undulating country, in some parts overgrown with open forests, and in others without trees, but well watered, and producing rich pasture. Between the Valley of St. Paul's River and the Basin of Fingal is a mountain-mass, which is connected on the east with the maritime range, and whose western extremity is marked by a dome-like summit, to which the name of St. Paul's Dome has been given. It is considered to rise 2800 feet above the sea-level. After the confluence of the two principal branches, the South Esk turns westward, and flows along the base of the Eastern Tier, so that between the river and the mountain south of it there is only a narrow strip, with an undulating or hilly surface, which however has a good soil. North of the river the valley extends to the base of the Ben Lomond range, a distance of five or six miles: the intervening ground resembles in general the St. Paul's Plains, being better adapted for pasture than for agriculture, and partly covered with thin forests. Thus the valley continues to the gorge above the mouth of Ben Lomond Rivulet.

North of the Upper Valley of the South Esk extends the *North-Eastern Mountain Region*, the whole of which is probably occupied by mountains; but the interior of it has not been explored, and only the outskirts of it are known. The country along the Bay of Fires, between Cape St. Helen's and Eddystone Point, is of considerable elevation, but partly well wooded and partly covered with a fine growth of grass. This tract is supposed to be fit for pastoral settlements. North of Eddystone Point the mountains are several miles from the shore: they have only been seen from a distance, and appear to constitute one continuous mass, broken in a few places by ravines, by which small rivers issue from them. There are no striking summits, except Mount Cameron, between Eddystone Point and Ringarooma Bay, but its elevation is not known. The mountains are generally wooded. The flat country between these mountains and the sea, from Eddystone Point to the mouth of the Tamar, is watered by numerous small streams, but the soil is generally dry and sandy, in some places overgrown with bushes or short, crooked trees, and in others covered with swamps, in which only tea-bushes are found. There are a few tracts which have a better soil, and might be cultivated, as on the banks of Piper's River. The best portion of this region is the valley of the North Esk, which opens to the west, and stretches eastward into the mountains on the north of the Ben Lomond range. This valley however is narrow, and contains very few tracts adapted for agricultural purposes, and the number of settlements is small, though the proximity of the town of Launceston affords a ready sale for their produce. A ridge of sterile but wooded hills runs along the southern side of the river, and continues to the banks of the South Esk, where that river, about a mile above Launceston, runs in a narrow valley for a mile, and at the point where it leaves that valley forms a cataract about 40 feet high.

The gorge through which the South Esk flows above Launceston separates the valley of the Tamar, which lies north of it, from the Basin of Lincoln, which extends south of it. The Tamar is only a deep inlet of the sea, which begins at the town of Launceston, and where the two Esks fall into it. Its length to Port Dalrymple in a straight line is about 30 miles, but measured along its numerous bends it is 43 miles. The tides come up to Launceston, at which place the inlet is only 60 yards wide, yet vessels of 150 tons may ascend to the town. The width of the navigable channel is 20 yards, nor does it widen for two miles below the town, and it is very narrow 10 or 12 miles farther, though the inlet itself widens to three-quarters of a mile. Ten or twelve miles below Launceston the inlet alternately expands to a breadth of three miles, and contracts to a mile, so as to appear like several small lakes connected by short channels. In this part are several shoals and sand-banks, and they only disappear about 15 miles from the sea. It is a great obstacle to the navigation of the river that the wind always blows either directly up or down it, so that a vessel is often obliged to depend upon the tide, and it sometimes happens that a passage from Port Dalrymple to Launceston occupies two or three weeks. The valley of the Tamar, measured between the summits on the two sides of the river, is about eight miles wide, but two or three of them are occupied by the declivities, though these declivities are rather steep. Thus the cultivable ground, if the extent of the inlet itself is subtracted, varies between three and six miles. Near the town of Launceston, and to a distance of about 11 miles north of it, the country on both sides of the river possesses a considerable degree of fertility, and is well settled; but farther down the eastern banks have a dry sandy or stony soil of very inferior quality, which is still uninhabited. On the left bank of the river the soil is much better, and there the settlements are numerous, though not so numerous as near Launceston.

The *Basin of Lincoln*, so called from the hundred of Lincoln, which occupies the centre of it, is the most fertile portion of Tasmania. It includes on the east the lower valley of the South Esk, extending to the western base of Ben Lomond, and on the west reaches the eastern base of the Western Tier. It is separated from the Northern Elevated Plains by the hilly and woody tract called Epping Forest. On the north it is bounded by the ridge of hills south of Launceston, and the mountains which line the northern banks of the Mæander as far as the mouth of Quamby's Brook. It extends from south-east to north-west about 25 miles, and as much from north-east to south-west. This gives an area of 600 square miles. This basin is watered by several large rivers, which unite, and ulti-

mately fall into the South Esk before it enters the above-mentioned gorge. These rivers are, from east to west—Elizabeth River, Macquarrie River, Lake River, Penny-royal River, and Meander or Western River. The surface and the soil of the Basin are not uniform. East of the South Esk the higher country chiefly consists of plains, either destitute of wood or thinly wooded, and well adapted for sheep: the wide bottom of the rivers yields rich crops. The country between the South Esk and Lake River consists of wide valleys along the courses of the rivers, and narrow ridges of hills between them, which however in some places attain a considerable elevation above their bases. These hills are generally wooded, and though the soil on their declivities is good, they are at present only used as pasture-ground: the wide level tracts along the watercourses have a very fertile soil, most of which is under cultivation. The most level portion of the basin is that which is west of Lake River, for in this district the uplands do not rise much above the bottom of the valleys, extend with an undulating surface, and are seldom interrupted by high hills. Like the bottoms, they were formerly clothed with trees, except on the very margins of the rivers, but nearly the whole of the region has been cleared and converted into fields. The soil of the bottoms is very rich, but they are subject to inundations, which however are of short duration. From the Basin of Lincoln all the corn is brought to Launceston, which is exported from that place, and which is the principal support of the population in the country round Sydney, whenever Australia experiences a dearth.

To the west of this basin is the *Western Tier*, or Western Mountains, which extend from the banks of the Lake River a few miles below the place where that river issues from the Arthur Lakes, in a west-north-west direction to the sources of the river Mersey, a distance of about 50 miles. The range lies between the southern plains and the Basin of Lincoln, but we have very little information respecting this region. A few summits have been noticed, as the Quamby Bluff, near the north-western extremity of the Basin of Lincoln, which is stated to be 3500 feet high, and the Extreme Western Bluff, at the west end of the region. It appears that the upper part of the range constitutes a tolerable level, on which only a few peaks attain 500 feet, and which is covered with small lakes, grass, and an alpine vegetation. Some low rocky ridges which run across it are covered with crooked eucalyptus and bushes. The width of this elevated tract does not exceed a few miles, but its elevation must be considerable, which may be inferred from the circumstance that even in January, which corresponds to our July, a heavy fall of snow was experienced, which covered the ground some inches deep. The whole vegetation, especially the frequent occurrence of lichens and mosses, proves its great elevation, which probably is not much less than 4000 feet above the sea-level.

At its northern extremity the Western Tier is of considerable width, extending from Quamby's Bluff to Extreme Western Bluff, a distance of about 25 miles. At its northern declivity extends a depression or valley, from east to west, which may be called the *Valley of the Meander*, as that river drains the greater part of it. Though a cart-road has been made through it, we are not acquainted with its extent from south to north, but we are informed that it extends westward to the vicinity of the Mersey where this river turns westward, being here divided from the valley of the last-mentioned river by a narrow offset of the Western Tier. This tract consists of level plains, which are generally without trees, but in several places there are small clumps of them, and they are occasionally intersected by narrow belts of forest, extending from the mountains to the banks of the rivers. Numerous rivers water this country, the soil of which is stated to be of good quality, and equally adapted to cultivation and the rearing of cattle.

Proceeding westward from the banks of the Mersey, two high and steep mountain-ridges must be passed before that region is reached which is called the *Surrey Hills*, and which constitutes one of the most remarkable features of Tasmania. It occupies the country for about 20 miles on each side of 146° E. long. and an equal extent on both sides of 41° 30′ S. lat., but properly speaking, its extent towards the south is not known, and it is even probable that it reaches the foot of the Eldon range, a chain of mountains which has been seen from a distance, and which probably is about 41° 55′ S. lat. This region gives origin to a great number of rivers, which run off in all directions. With the exception of a few rivulets originating near the coast, all the rivers which fall into the sea west of 146° 25 E. long. and north of 42° S. lat. rise in the Surrey Hills: they must therefore constitute the highest ground in this part of Tasmania. It is remarkable that the highest part of the region lies on its outer edges, for the region is surrounded on the east, and still more on the north and west, by hills which rise considerably above the general level, have extremely steep declivities, and narrow level tracts on their tops, but are otherwise covered with dense forests frequently matted together by underwood. Among the single summits are the St. Valentine's Peak, near the northern edge, which is 3000 feet above the sea, and the Black Bluff Mount, which is said to be 300 feet higher. The interior of the region is very different. Its surface is formed by a succession of low hills, which rise with so gentle a slope that it may be considered a plain, and it is intersected by small brooks, the sides of which are adorned with narrow belts of beautiful shrubs and trees. Whenever a hill rises to a higher elevation, its declivity consists of level and regular terraces, as if laid out by art, and the summit is crowned with stately peppermint-trees. There are many open plains of several square miles in extent without a tree. In general there are not more than ten trees to an acre. The hills are covered with a vigorous growth of grass. The soil is a dark vegetable mould upon a rich brown loam. The substratum appears to be gravel, which renders these hills perfectly dry, and fit for sheep-walks, for which purpose they now are used by the settlements which have been formed on them by the Van Diemen's Land Company. This country extends north of St. Valentine's Peak on both sides of the Emu river, where it appears even more park-like than farther south, being handsomely clumped with trees. This tract is called the Hampshire Hills. The elevation of the Surrey Hills above the sea-level renders the climate much colder than on the coast. Snow covers the ground for several weeks, which however must be considered as an advantage in a country where the soil inclines to dryness. It has also the benefit of abundant rains during autumn (March and April).

Between the valley of the Meander and the Surrey Hills on the south, and Bass's Strait on the north, is the hilly region of Devonshire. The mountains which extend from the gorge of the South Esk to the west of the Tamar north-north-west, and terminate on the sea with Point Flinders, appear to constitute a continuous range of moderate elevation. They are partly wooded and partly destitute of trees, and in some places covered with a very scanty vegetation of shrubs or grass. Farther west this region is very little known, except that the spaces between the rivers are filled up with mountains and high hills, and that these heights come close to the shores of the sea. Few, if any, settlements have been formed on it. This region extends westward to the banks of the Emu River.

West of the Emu River begins the *Great Plain* of Tasmania: it occupies the north-western portion of the island, extending along the northern coast from the Emu to Cape Grim, and along the western coast to the Arthur River. The narrowest portion of this plain appears to be between the Emu and Detention Rivers, where its width does not exceed 12 miles, and it terminates on the south at the Hampshire Hills. Farther west a continuous range of high hills, called the Campbell Range, forms its boundary, and terminates near the source of the Detention River with Dip Hill, a mountain of moderate elevation. The surface of this portion of the plain is strongly undulating, and in many parts even hilly. Near the shores it is overgrown with dense forests, which are made nearly impenetrable by the underwood, bushes, and ferns. But about three miles or somewhat more from the sea the forests are interrupted by a succession of small plains covered with grass and destitute of trees. They have a light dry soil, are well watered by springs and streams, and surrounded by excellent timber. The grass is coarse but plentiful: there are also some tracts fit for cultivation. West of Detention River the plain grows wider. From Dip Hill, at the source of the river, Hellyer distinguished the high grounds at Cape Grim and West Point, though they are of very moderate elevation. The plain, west of Detention River, exceed 15 miles in width. This large tract however is very ill adapted for colonization. The surface is generally level

and the water not being carried off, the country has been converted into an immense swamp. A portion of the swamp is overgrown by low tea-trees, and the remainder is covered with forests of eucalyptus and underwood. The higher grounds, which generally occur nearer the shores, have a sandy soil covered with heath or stunted trees. The only tract which seems to be applicable to useful purposes is along the sea from Cape Grim to the River Arthur: its width near the cape is several miles, but farther south it grows much narrower: the surface is hilly and partly stony. The soil has generally a tendency to sand, but it is thickly covered with kangaroo grass, and makes good pasture-ground for sheep, and in some places for cattle. Trees occur only at considerable distances from each other. It is probable that the plain continues south of Arthur River, but that it is of less extent there, as low hills have been seen at a short distance from the sea, which are dry and only covered with bushes, but behind them the hills rise much higher. These parts have never been visited.

The Arthur, whose mouth is near 41° 10′ S. lat., is a river of considerable size, and brings down a large volume of water. There is a bar across its mouth, on which the sea breaks with a heavy surf. Its middle course is not known, but it is supposed that the chief supply of its waters is derived from the Surrey Hills, and that two large rivers, which rise there, and are respectively called Hellyer River and Arthur River, unite in the country between the Surrey Hills and the western coast; and that by their confluence the Arthur is formed.

The other known rivers of the northern part of Tasmania are unimportant, with the exception of the Emu, which is navigable for boats for a few miles. With respect to the South Esk, which probably has a course of 100 miles, two of its principal branches, the Macquarrie and the Lake River, rise on the southern elevated plains, and the upper branches of these rivers interlock with rivers which flow southward to the Derwent. As other branches of the South Esk rise near the eastern coast, and others far to the west, it is probable that the area of the country which is drained by it and the North Esk does not fall short of 4000 square miles. The Tamar certainly receives the drainage of a much larger extent of country than any other river of Tasmania.

Climate.—As no meteorological observations have been published on the climate of Tasmania, we only know its peculiarities by comparisons which have been made between it and that of England and Sydney. There is a considerable difference between the climate of Hobart Town on the southern, and of Launceston on the northern coast. The climate of Hobart Town seems to be greatly influenced by the range of mountains west of the town and the vicinity of the open ocean. The vague statement of Breton, that the mean temperature in summer is 70°, and in winter between 40° and 48°, is apparently not derived from observations, and is not much to be relied on. The climate of Hobart Town is extremely changeable. Heat, cold, rain, and sunshine succeed each other with a rapidity which is rarely observed in any other part of the globe. The winter is not more constant than the summer: the same alternations, with the addition of hail and snow, follow each other in quick succession; but the snow never remains on the ground beyond a few hours, whilst at Launceston it falls in greater quantity, and covers the ground for many days together. This statement does not agree with another, according to which the average number of days on which rain actually falls does not exceed fifty or sixty in the year, and that, except on these days, the sky is clear, the sun brilliant, and the atmosphere dry, pure, and elastic. Hot winds sometimes occur, which occasionally raise the thermometer to 108°. They blow from north and north-west, and rarely last a long time; but during their prevalence vegetation is greatly injured. However warm the middle of the day may be, it is invariably attended by a morning and evening so cool as completely to brace the body, and to counteract any enervating effects of the climate. Thunder-storms are less frequent than in Australia, but violent gusts of wind sometimes occur, which cause great destruction in the forests, and the coasts are visited by much boisterous weather. Along the western coast strong south-westerly winds prevail nearly all the year round, and render this tract almost inaccessible on account of the want of harbours. During some seasons of the year westerly gales continue for many weeks in Bass's Strait, so that vessels sailing from Sydney to the Atlantic find that they save time and labour by going round the island. The climate is very healthy: no epidemic or contagious diseases have been observed, and acute diseases are generally mild and of short duration, and yield more easily to the usual remedies than in any other country.

Productions.—The mineral wealth of the island is not known. The existence of gold and silver rests on statements which cannot be relied on; but that of copper is certain, and this metal is rather abundant in some of the hills on the north coast. Iron-ore is abundant, but not yet turned to account. Some ore which was subjected to a trial yielded 80 per cent. of metal. There are also indications of lead, zinc, and manganese; and those of coal have been found all across the island. Roofing-slate of good quality abounds in many parts: on the Arthur such extensive layers were discovered by Hellyer, that in his opinion the whole globe might be supplied with them. Salt is obtained from the salt lakes of Salt-Pan Plain, and is also got from sea-water on Bruni Island, but not in sufficient quantity to supply the consumption. Salt is imported from England. Excellent sandstone for building is found in all parts of the island, and marble is met with at various places. Basalt rocks are frequent along the coast and in many places in the interior.

No tropical grains or plants are cultivated, but all grains cultivated in England succeed well. Wheat is of excellent quality, weighing generally from 62 to 64 pounds the bushel: considerable quantities are exported. Barley and oats will only thrive in a good soil. Vegetables of all kinds are most plentiful, even those of Southern Europe, the production of which requires in England much care and expense. The apple-orchards are of great extent, and the making of cider is attended to. Peaches, apricots, and nectarines grow very abundantly. Damsons, plums, cherries, pears, and quinces are also grown; but the fruit is of inferior quality, for want of care. Grapes are of good quality, but no good wine has yet been made. Raspberries, gooseberries, and currants are abundant and of good quality: strawberries are also good. All these fruits have been introduced by the settlers.

The domestic animals of Europe have been transplanted to Tasmania, and thrive very well. Sheep are most numerous. Wool and live stock are exported to a great extent. Black cattle are also numerous, and many head are annually exported; and also some horses. Fowls are extremely numerous, but geese and ducks are not much kept.

The spermaceti-whale is very abundant in Bass's Strait, and many of them are annually taken, but more by the inhabitants of Australia than by those of Tasmania. Black whales abound in all the seas round the island, and a very lucrative fishery is carried on along the southern coast. Whalebone and train-oil are important articles of export. A small quantity of spermaceti-oil is also exported. Seals are found on most of the smaller islands, and especially on the eastern coast: their skins constitute an article of export. Some of the animals of the forests are common to Australia and Tasmania. The native tiger (Hyæna opossum) and the native devil (Dasyurus ursinus) are peculiar to Tasmania, and perhaps also the wild cat. These are the only carnivorous animals in Tasmania, with the exception of some species of weasel. There are three or four species of kangaroos, two kinds of opossum, the bandicoot, the native porcupine or echidna, the wombat, the opossum-mouse, and the ornithorhynchus paradoxus. All the wild animals of Tasmania, with the exception of the native devil, are very easily tamed and domesticated. The birds are numerous: these are emus, black and white cockatoos, parrots, two kinds of magpies, the laughing jackass, hawks, eagles, the carrion crow, pelican, black swan, ducks, teal, widgeons, quails, snipes, and bronze-winged pigeons: the last-named are considered the most beautiful birds in the island. There are likewise several varieties of snakes, two or three of which are venomous; also centipedes, scorpions, and large ants. Fish are said to be more numerous than on the coast of Australia, but they have not been further noticed. The river-fish are small.

None of the forest-trees or shrubs yield an edible fruit. They are all evergreens, and have that sombre olive hue which prevails in Australia, without a single lively tint, except that of the native cherry, to break this monotony. The most numerous are the eucalyptus, which attains an

immense size. From one of its species a manna is obtained, which tastes like some kind of sugar-plum: it forms concretions on the leaves and smaller branches; but is found in such trifling quantities, that it would never repay the trouble of collecting it. The most useful tree is the stringy bark, which is used for building and fencing; and the blue gum, of which most of the boats in the colony are built. The smaller trees are used for masts for small vessels. The peppermint, so called from the taste of the leaves, is a large tree, but of very little use. The Huon pine is the most beautiful wood in the island: it is very superior both in colour and substance to the Norway deal, but is scarce and difficult to be had. The Adventure pine, so called from the bay of that name, is a species of pine adapted for house-work and furniture; but it is not common. The black and silver wattle (mimosa) are used in house-work and furniture, but they are of diminutive size. The bark of the black wattle is exported to England in large quantities. The tea-tree is a shrub which grows in wet situations: an infusion of its leaves makes a pleasant beverage, and, with a little sugar, forms an excellent substitute for tea.

(Flinders's *Voyage to Terra Australis;* Rossel's *Voyage d'Entrecasteaux*, &c.; Evans's *Geographical, Historical, and Topographical Description of Van Diemen's Land;* Widowson's *Present State of Agriculture, &c., in Van Diemen's Land;* Bischoff's *Sketch of the History of Van Diemen's Land, &c.;* and Breton's *Excursions in New South Wales, &c.*)

History.—In 1803 Lieutenant Bowen, commissioned by the government of New South Wales, landed on the east bank of the Derwent, and formally took possession of Van Diemen's Land as a place of settlement. In the following year Colonel Collins, the first lieutenant-governor, arrived, and established the seat of government on the west bank of the Derwent: he gave to the spot the name of Hobart Town, in compliment to Lord Hobart, then secretary of state for the colonies. Colonel Patterson arrived in the same year in the Tamar, and formed an establishment on its west bank. Colonel Davey succeeded to the government in 1813, and under his administration the ports of the colony were first opened to commerce, only transport vessels from New South Wales having previously been admitted. Colonel Sorell was appointed lieutenant-governor in 1817, and in 1819 the immigration of free settlers from England commenced, the colony having been previously exclusively formed of criminals sent from New South Wales for crimes repeated there, and of the civil and military officers charged with their superintendence. Till the year 1824 the government was subject to that of New South Wales, and the chief civil and criminal questions arising in Van Diemen's Land were decided in Sydney. The only courts in the island were those of police magistrates, who had cognizance of petty crimes, and a court for the settlement of questions of value not exceeding 50*l.*, in which a military officer presided. Great inconvenience and mischief resulted from this state of things. Civil cases were mostly settled by compromise; and in criminal cases, the most dangerous offenders were allowed to escape.

The most important steps in the progress of the colony were made between the years 1824 and 1836, during the administration of Colonel Arthur:—

In 1824, the population was		12,643;	in 1835 it was	40,283
,,	Number of vessels which arrived	33;	,,	234
,,	Sailed outwards	35;	,,	225

(*Statistical Returns of Van Diemen's Land, compiled by the Colonial Secretary, Hobart Town, dated 10th Oct.*, 1836.)

Roads were formed and bridges constructed in different parts of the island; wholesome laws were introduced; the tone of public opinion was improved, and the fruits of enterprise and industry were secured by an improved police system.

That which chiefly contributed to the progress of the settlement was extraordinary encouragements held out to emigrants. Grants of land were made to them proportioned in extent to the capital which the colonist was prepared to invest in stock and in agricultural improvements. The labour of convicts was not only liberally provided, but the colonist was rewarded for employing it by allowances of rations for himself and the convicts in his employ for some time after his arrival; and at a later period, when this remuneration, or, to speak more correctly, this additional bonus, was withdrawn altogether, labour was obtained on the easy conditions of the settler providing clothes, food, and lodging to the convicts assigned to him. There were other advantages likewise incident to the penal purposes for which the colony was founded, which assisted its progress. The character and condition of the majority of the population required that a civil and military force should be established on the island, which, being maintained by the British government, introduced so much capital annually. From the magnitude of their crimes or their dangerous character, it was not deemed safe to remove from under the immediate coercion of government a large number, amounting latterly to some thousands, of the convicts, and their punishment was made to consist of hard labour at works of public utility, such as the making and repairing of roads and bridges. While the expense of maintaining these convicts was defrayed by the British government, the settlers contracted to supply the various articles which made up that expense. They were thus in a twofold manner benefited: they had labourers employed for their advantage at the cost of a third party, and they were enabled to derive a profit from the payment of that labour. With such circumstances in its favour, with a healthy climate, and a soil of average capabilities, it was impossible that Tasmania should not advance. Its progress has accordingly been steady, scarcely subject to any of those variations to which young colonies are exposed;—to none indeed but such as may be strictly referred to that gambling spirit of speculation which the occasional great profits of an imperfectly established market are apt to engender.

In 1831 the system of colonization by free grants of land was abolished, and since then land has been sold by auction, first at the upset price of five shillings per acre; subsequently at twelve shillings; and latterly at twenty, at which it remains. The system of assignment of convict labour is at present only partially in force, and it is intended to discontinue it. The colony has probably advanced to that state in which the advantages (advantages not without some drawbacks even in the best case) of compulsory labour have ceased, and in which the minute care, the good will, the steady subordination of the servant are requisite to the success of industrial operations.

Trade and Commerce.—The staple article of production in Tasmania is wool, the amount of which exported in the year ending December, 1838, exceeded 2,490,990 lbs. (*Parliamentary Report on Wool and Woollen Manufactures*, April 29, 1839.) The value of this wool in the English market has, according to the Statistical Report of the secretary to the government of Van Diemen's Land, quoted above, ranged from 1*s.* 6*d.* to 2*s.* 6*d.* per lb. A considerable trade has during the last five years been carried on with the new colonies of Australia, South Australia, and Port Phillip, in sheep, the prices of which have varied in that time so much as from seven shillings to sixty shillings per head.

Owing to the smallness of the demand for grain, and the great outlay required in the clearing of land, agricultural operations have been slow in Tasmania. This has likewise been accounted for by the circumstance that few practical farmers emigrated to the colony. 'The earlier settlers were chiefly artizans of intemperate habits, unacquainted with husbandry, and disinclined to attain a knowledge of it. Still (says the writer from whose account we quote, himself for ten years a colonist of Van Diemen's Land) they obtained and located themselves on grants of land; turned up the soil, and threw grain into it; and it being grateful, repaid their rude essays with bountiful harvests. This was sufficient. When one piece of land was exhausted, another was broken up, and so on in constant succession. Fresh

settlers continued to arrive, and obtained land too; and as these were not agriculturists either, they had to copy their predecessors. Such was the progress of agriculture in Van Diemen's Land; and such is its condition at the present period (1838). The diversity of the climate in the different districts is still overlooked; the seasons are scarcely ascertained, and the proper times for sowing remain doubtful, and are adopted irregularly.' (*The Condition and Capabilities of Van Diemen's Land*, by John Dixon, 1839.) Van Diemen's Land however produces not only a sufficient supply of grain for domestic consumption, but has contributed for several years to supply the deficiency in New South Wales; and in the opinion of local writers there is a probability of its being the granary of the southern hemisphere. Oxen are generally used, instead of horses, in ploughing, and the implements of husbandry are those in use in England.

Oil constitutes the second great article of export from Tasmania. Whales of the black species were at one time taken in great abundance in the bays on the coast of the island; but we find that Mr. Dixon confirms the apprehensions expressed by an earlier writer on the colony (*Observations on New South Wales and Van Diemen's Land*, by John Henderson, Calcutta, 1832) of their being driven away by an injudicious prosecution of the fishery at all seasons of the year. Sperm oil, as well as that of the black whale, is exported. The returns derived from this source are still considerable.

Among the miscellaneous exports are bark, kangaroo skins, whale-bone, and potatoes (to Sydney); but the aggregate of the returns from these articles is trifling.

There are about eight banking establishments, with branches in the chief towns. They are all joint-stock, the shareholders being responsible to the full extent of their property. They circulate notes of one pound and upwards. Bank interest at a recent date was ten per cent., and at the period at which this article is written it cannot be affirmed with confidence whether it is lowered. There are also several companies for the insurance of life and property.

Divisions of the Island.—Original'y Tasmania was divided into two counties, but it has since been subdivided into police districts, and more recently into thirty-six counties. We are not aware however that any map embracing the county divisions has been published, and in the following details we adhere to the divisions into districts. The district of Hobart Town is bounded on the east by the river Derwent, and on the south and west by the river Huon, on the north by New Norfolk and Richmond districts. It comprises an area of about 400 square miles, or 250,000 acres, of which not more than about 4000 are yet in cultivation. Richmond is bounded on the south and east by the sea, on the north by Oatlands, and on the west by New Norfolk: its towns are Richmond, Sorell, and Brighton; besides which it includes several large agricultural establishments: it contains about 1050 square miles, or 672,000 acres, of which about 22,000 are estimated to be under cultivation. New Norfolk is bounded on three sides by Hobart, Clyde, and Richmond districts, and on the west and south-west by unlocated lands. The towns are New Norfolk and Hamilton, and it comprises about 1500 square miles, or 96,000 acres, a great portion of which is barren and rocky: about 6000 acres are in cultivation. Clyde is bounded on the west by unlocated lands, and on the other three sides by Norfolk Plains, Campbell Town, and Oatlands districts: its only town is Bothwell. This district comprises 1700 square miles, or 1,088,000 acres, about 5000 of which are in cultivation. Oatlands, bounded on the south by Richmond, east by Oyster Bay, west by the Clyde district, and north by Campbell Town, contains 900 square miles, or about 576,000 acres. Oatlands and Jericho are its towns. Upwards of 4000 acres are in cultivation. Campbell Town, bounded on the south by Oatlands, east by unlocated lands extending to the sea, west by the Clyde and Norfolk Plains, and north by Launceston district, comprises about 1260 square miles, or 850,000 acres. Its towns are Campbell Town and Ross. The land is rich and fertile, having 8000 or 9000 acres in cultivation. Norfolk Plains are bounded on the south by the Clyde, east by Campbell Town and Launceston districts, and by the territories of the Van Diemen's Land Company, and north by Bass's Straits. This district comprises 2250 square miles, or rather more than 1,500,000 acres. Longford and Westbury are the townships. About 8000 acres of land are supposed to be in cultivation. Launceston district is bounded on the south by Campbell Town, on the west by Norfolk Plains districts, and on the north and east by the ocean. Besides the town of Launceston it has Perth and George Town. The district covers 3800 square miles, or about 2,352,000 acres; not more than 10,000 or 11,000 of which are in cultivation. Oyster Bay is bounded on the south by Richmond, west and north by Oatlands and Campbell Town districts, and east by the ocean. It contains about 900 square miles, or 576,000 acres, of which between 2000 and 3000 are estimated to be in cultivation. (Martin's *Van Diemen's Land; Hobart Town Annual.*)

The other divisions of the island are—the Van Diemen's Land Company's territories, comprising nearly half a million of acres on the north-west corner of the island, bounded on two sides by the sea, on the others by crown lands not yet located, and by the settled districts of the Norfolk Plains; and Tasman's Peninsula. Of the purposes to which Tasman's Peninsula is applied, an account is given in the article TRANSPORTATION.

Towns.—Of the towns mentioned in the preceding outline of the territorial divisions of Tasmania, only two or three are worthy of notice, the others being little more than villages or sites laid out for towns on which a few straggling houses are built. 'Hobart Town is built upon an undulating surface, receding from a cove on the left of the Derwent. Seen from the water, it seems to run up before you on a variety of ascents, and to spread itself abroad upon the hills in the distance. Mount Wellington, a great mountain, which during nine months in the year is capped with snow, and which rises four thousand feet above the level of the sea, stands at the back, in darkness and sublimity, and overlooks the surrounding scenery. The town is laid out with judgment. There are about twenty streets, all wide, and dividing or intersecting one another at right angles. A narrow and shallow rivulet, which takes its rise from Mount Wellington, flows through the town, and affords the inhabitants their only supply of fresh water. All the streets are macadamized, and none are flagged. . . The houses bear no common aspect. Some are of brick, others of stone; but all, instead of being slated, are roofed with shingles. As every proprietor has been guided by his own taste in the structure of his house, few are built alike or upon the same plan; and as he was not restrained by the government to a settled line, they are often planted in a zigzag position. The town covers a great deal of ground, but little of it after all is built upon. A tree is seen sometimes standing in the midst of houses, and a house often in the midst of trees. Dwellings have been erected long before the streets were made, and the town being upon a very irregular surface, some of the buildings in consequence now occupy very awkward situations. On one side of a street they are often elevated much above the level; while, on the other they are sunk considerably beneath it. Shops are scattered all over Hobart Town; but the business thoroughfare is confined to two streets. Some of the shops are showy and respectable, even tasteful and elegant; displaying an appearance equal to that of many in London. The householder is as particular in decorating the interior of his house as he would be were he in England, and hence his furniture is not inferior to that of those of his own rank in the mother country.' (Dixon's *Account.*) In 1839 there were upwards of fifteen hundred houses in Hobart Town. Among the public buildings may be named three handsome Episcopalian churches, and one Presbyterian, one superior edifice belonging to the Wesleyans, besides several of inferior description, the property of the same body, two Independent chapels, and a Roman Catholic church, by this time probably completed. The Government House is an irregular structure, made up of continual additions to an originally small building, and is shortly to give place to another house intended for the residence of the lieutenant-governor, of which the foundation has been laid. There are custom-houses, a handsome theatre, a court-house, and police-office, and an exchange has been set on foot. There are many benevolent and religious institutions and societies established, and two or three of a literary character. Seven papers are published, most of which are weekly, besides an official gazette and two gratuitous advertising sheets. The population of Hobart Town, including the convicts and military as well as the free inhabitants, in the town and its immediate precincts, is not less than ten thousand. The

following returns exhibit the amount of the Hobart Town imports and exports, with the places from which received, and to which sent, for the year ending December, 1837:—

Imports.

Great Britain	£230,950
New South Wales	95,865
Mauritius	8,147
Calcutta	4,397
Canton	1,541
Manilla	380
Singapore	1,876
Cape of Good Hope	3,620
United States	490
Hamburg	860
	£348,126

Exports.

Great Britain	£166,585
New South Wales	53,980
Swan River	95
South Australia	11,414
New Zealand	1,699
Mauritius	858
Calcutta	590
Canton	15
Valparaiso	60
	£235,266

In a comparison of these returns it is pointed out by the editor of the 'Van Diemen's Land Annual,' from which publication they are taken, that the apparent balance exhibited against Hobart Town is diminished when it is considered that a great portion of this balance consists of property imported by individuals who have settled in the colony. We have not been able to procure authentic returns of a later date than those quoted; but it may be concluded that the value both of the exports and imports of Hobart Town has greatly increased since.

Launceston, the second town of the colony, is situated at the confluence of the North and South Esk, which there form the Tamar, flowing about forty-five miles, when it disembogues into the ocean at Bass's Straits. It is 124 miles from the capital of the colony. Launceston is situated in a marshy spot, and is neither in beauty nor in the promise of health to be compared to Hobart Town. The enterprise of its inhabitants, aided by the vicinity of the richest settlements in the island, is however great, and it is not improbable that this town will outstrip its southern competitor in commerce. The imports in the year 1837 were 191,843*l.* in value; the exports being 264,599*l.*, upwards of twenty-nine thousand pounds above those of Hobart Town; and in subsequent years it is believed that the difference is much greater in amount. Launceston contains many churches, the property of different religious denominations, and the private and public buildings are not destitute of architectural beauty.

The highway between the northern and southern capitals of Tasmania is for the most part well laid out; there are inns along this road at short distances from one another, the accommodation in which is not far from equalling the same on the roads of England. Passing from the highway into what were not long since unpeopled woods, the fashionable vehicle as well as the rustic waggon of the settler is to be seen driven along cross roads which are everywhere in process of formation; and here and there, only partially obscured from a distance by the thick and sombre Australian foliage, are to be seen mansions almost baronial, superseding the rude shelter of the aborigine, and the hut, almost as rude, in which the colonist first lodged.

Population.—In 1838 a census of the free inhabitants of Van Diemen's Land was made with a reference to the religious denominations to which they belonged, which exhibited the following summary:—

Church of England	16,094
Church of Scotland	2,551
Church of Rome	2,288
Wesleyans	1,289
Baptists	175
Independents	635
Quakers	80
Jews	132
	23,244

The accuracy of this return, in so far as it referred to the relative numbers belonging to different religious denominations, was generally questioned; but the aggregate representation of the amount of population, we believe, was admitted. No great increase by immigration has taken place since, and the new colony of Port Phillip has attracted many from Tasmania. The return of the number of male and female convicts for the same year gives:—

Male convicts	16,129
Female convicts	2,139

An account of the convict system of Van Diemen's Land is reserved for the article TRANSPORTATION; but the following returns are introduced here, as they bear upon the general social condition of the island:—

Return showing the Disposal of the Convicts in 1838.

Sentence of transportation expired	793
Free and conditional pardons	365
Transported to New South Wales	23
Transported to Port Arthur	1,306
Absconded in 1837	225
Died	167
Executed	4
Confined in gaols	69
Sick in hospitals	82
Invalid establishments	126
Employed in chain gangs	537
Employed in public works	2,583
Artificers on loan to settlers	262
Assigned to settlers	6,023
'Tickets of leave,' or conditionally free	3,960
Constables and field police	395
Missing	39
	16,959*

Female Convicts.

Sentence of transportation expired	163
Conditional pardons	52
Died	16
Sent to New South Wales	1
Total number remaining	2,086
	2,318*

State of Crime.—If Van Diemen's Land has greatly benefited in an economical sense by being a settlement for convicts, it has undoubtedly suffered from this cause in a moral sense. A paragraph will not suffice to give an accurate idea of the general moral condition of the population. Referring therefore to the *Transportation Report* of 1838, and to a volume entitled 'Australiana,' by Captain Maconochie, R.N., K.H. (Parker, Strand, 1839), we shall introduce here only a few details and accompanying explanations taken from the last of these authorities. 'Notwithstanding the strictness and vigilance of the police of this colony, notwithstanding the length of time during which the prisoners have for the most part been subjected to its minute supervision, notwithstanding the decided tendency of the age to moral improvement, and notwithstanding the great influx of free settlers into the colony within the last ten years and the high personal respectability of most of them, the proportion of crime and disorder to the entire population is not only very great, but appears in many particulars even to be on the increase.' From No. 33 of the *Statistical Papers* drawn up by the colonial secretary, it appears that convictions for drunkenness were, in 1824, as $3\frac{47}{128}$ to 100 of the whole population, and in 1832 as $9\frac{23}{25}$. Convictions under penal statutes of free persons in 1824 were as $5\frac{13}{68}$ to 100, and in 1832 as $7\frac{24}{75}$; and general misdemeanors by convicts in 1824 were as $11\frac{1}{18}$ to 100, and in 1832 as $43\frac{47}{57}$. After 1832 the returns are differently made, and the several heads of offence are multiplied; yet, with few exceptions, the same general fact is evident. Thus drunkenness among the convicts in 1833-34-35 was as $4\frac{33}{148}$, $4\frac{44}{135}$, $4\frac{58}{169}$ respectively to 100. The tendency, as is well known, in English society, unless in peculiar circumstances, has been rather steadily, during the last ten or twelve years, towards sobriety. Felonies disposed of summarily were in like manner, in 1833-34-35, as $2\frac{24}{110}$, $4\frac{118}{135}$, $3\frac{161}{169}$ to 100; among free people, as $7\frac{123}{152}$, $5\frac{15}{23}$, $3\frac{68}{113}$ to 100; and what are called various offences, not included under previous heads, as $1\frac{281}{511}$, $3\frac{140}{377}$, $4\frac{232}{169}$ to 100. Cap-

* We have not introduced the returns of convicts arriving from England, which explain the difference between these totals and those previously quoted.

tain Maconochie quotes returns of the convictions before the supreme court and quarter-sessions, on which he remarks: 1st, that the ratios throughout to the whole population are enormous, convictions in England being scarcely 1 to 1000 inhabitants, and in Scotland only 1 to 1300, those for Van Diemen's Land being, in 1835, 1 to 105$\frac{378}{387}$; 2nd, the extreme vigilance of Van Diemen's Land police tends to prevent the commission of great crimes, while the latitude given to its summary jurisdiction makes it unnecessary to bring medium offences under the cognizanee of the higher courts; 3rd, the pecuniary prosperity of Van Diemen's Land is advancing, which shows that dissipation, not distress, leads there to crime. Comparing the state of petty crime in the colony to that in London, it is found that in Van Diemen's Land, for drunkenness alone, the convictions among the free population are about 14 per cent.; whereas in London, for every description of petty offence, they are little more than 5 per cent.; and Captain Maconochie remarks that the returns in Van Diemen's Land refer to a mixed population of agriculturists as well as town residents, which makes the comparison still more disadvantageous. As general characteristics, he mentions dissension, bitterness of feeling, improvidence, and a reliance upon authority, instead of moral influence, in the relations of master and servant. He remarks also that there is a low standard of moral principle, a characteristic which, though not so obvious, is radically more detrimental than great occasional vices, and one which it is more difficult to correct. But as he frequently points out in his interesting work, and as there is a necessity of remarking here, in strictness a social character can scarcely be predicated yet in reference to the population of Van Diemen's Land; the colony is not old enough to have moulded the character of its inhabitants; and, amid much that is painful in the aspect of society, there is also much of an opposite character—individual benevolence and public spirit.

Government.—Van Diemen's Land is administered by a lieutenant-governor, who is assisted by two councils. The lieutenant-governor has the initiative of all laws. The councils are called the Executive and the Legislative. The former is composed of official members, and the latter of official and non-official: all are appointed by the crown, and removable at the governor's pleasure, with the sanction of the crown. If two-thirds of the legislative council are opposed to any act proposed, it cannot pass: the reasons of dissent are entered. Practically however this provision is of no value, for half of the council are salaried officers of the local government. Laws passed by the council must, within seven days, be enrolled in the Supreme Court; and fourteen days from such enrolment, unless the judges declare them to be repugnant to British law or the charter, or letters patent of the colony, they come into operation. In case of objection being made, the governor and council re-consider the act. The laws of England, so far as they can be applied, are recognised, and embodied in local enactments.

The judicature consists of a supreme court, having two judges, of courts of quarter-sessions, and courts of requests, which last are sometimes called courts of conscience, and have jurisdiction in matters to the extent of ten pounds. Criminal offences are tried in the Supreme Court by seven military officers as a jury; civil cases, by a judge and two assessors, magistrates of the colony appointed by the governor, and who are open to challenge by the parties, the challenge being determined by the judge: if the assessors do not agree, the judge has a casting vote. The Supreme Court may, on the application of either party in an action, summon a jury to try it. This court declares insolvencies and distributes effects: it likewise possesses equitable and ecclesiastical jurisdiction. The total estimated expenses of the judicial establishment for the year 1839 was 15,266*l.* 7*s.* 6*d.*

In all the most populous districts of the island there are police magistrates, who sit daily for the trial of petty offences: their decisions are subject to the approval of the governor, who is advised by the chief police magistrate. A large constabulary force is maintained, composed chiefly of convicts. The total police estimates of Van Diemen's Land for 1839 exceeded 26,000*l.*

The ecclesiastical provision is of the most liberal character. Three religious denominations, the Episcopalian, Presbyterian, and Roman Catholic, receive allowances from the state. They are equally provided for in proportion to the respective number of their bodies, and the clergy of each have the same political status. In the towns the subscription of two hundred adults (three children or persons under a specified age being considered equal to one adult) to a paper, intimating their connection with one of the denominations named, desiring to have a church erected for the use of such denomination, and the contribution of at least 300*l.* towards its erection, are the conditions on which the government erects such church and provides for the maintenance of worship in it. In the rural districts the fulfilment of these conditions by eighty adults, residing within a radius of ten miles, is required. The sum expended by the government on the erection of a church is equal to that raised by private contribution. The stipend allowed to the clergy in the towns is 250*l.* annually, and to those in the rural districts 200*l.* A glebe and ten acres of land are also allowed, and in certain cases a further sum of money for the feed of a horse. The Wesleyans have an annual grant of 400*l.* voted in their favour by the legislative council.

The Church Act has stimulated the erection of churches in the colony, so that there is now no deficieney, comparatively speaking, except in the districts in which there is a very limited population. The estimated expenses of the ecclesiastical establishment for the year 1839 amounted to 7055*l.* 14*s.* 11*d.*; but the Church Act had not, at the period at which that estimate was made, exerted so much influence as it has since done, and at present it is certain that the ecclesiastical outlay is considerably above the sum stated. Numerous places of worship have been erected throughout the settled districts of the island by Protestant denominations, not embraced in the government scheme of support. The government assists in the maintenance of Sabbath schools in connection with the different churches.

Liberal provision is made for juvenile education, on the principles chiefly of the British and Foreign School Society; and, besides a collegiate institution, founded and maintained by the government, one has been projected by the colonists, for which subscriptions have been raised. The site of the first is at New Norfolk; the second is to be established at Campbell Town. These institutions are to be in the first instance superior grammar-schools; and gradually, as professors can be obtained, and there is a demand for the higher branches of learning, they are to receive the character of colleges.

In the estimates of the expenditure of Van Diemen's Land for the year 1839, a sum of 4000*l.* is put down for schools; and an additional sum of 2751*l.* for the 'Orphan Schools,' in which the offspring of convicts are educated and maintained. The expense of the collegiate institution is not included in the sum of 4000*l.*: its foundation had not been laid at the date of that estimate.

The revenue of the colony is derived from duties on spirits—10*s.* per gallon on brandy; 7*s.* 6*d.* on hollands or geneva, West India Rum, or British gin; 1*s.* 6*d.* per pound on tobacco: from licences — 25*l.* per annum for licence to sell spirits; 3*l.* 3*s.* for auctioneer's, and 4*l.* 4*s.* for marriage licences: from the fees of public offices, fines, &c. It has increased progressively for many years. In 1826 it amounted to 34,655*l.* 0*s.* 1½*d.*; in 1830 it was 62,018*l.* 7*s.* 8½*d.*; in 1835 it was 91,320*l.* 19*s.* 9½*d.* (*Statistical Report* of the Colonial Secretary.) With the addition of the revenue derived from the sale of land in these years, it amounted to 65,178*l.* 17*s.* 0½*d.* in 1830; to 106,640*l.* 8*s.* 2*d.* in 1835; in 1840, the revenue, it was estimated, would amount to 200,000*l.* Part of this revenue is appropriated to the immigration of labourers, and the rest to the civil, judicial, ecclesiastical, and miscellaneous expenses of the colony, which are not borne by the British government. The expenditure of the year 1837 amounted to 136,856*l.* 1*s.* 6*d.*; for 1838 the estimated total was 124,143*l.* 14*s.* 4*d.*; for 1839, 111,770*l.* (*Abstract*, dated July 5th, 1838, Colonial Secretary's Office, Hobart Town.)

Natives.—The aborigines of Van Diemen's Land so closely resemble in physical character those of Australia, as to leave no doubt of their origin being the same. [AUSTRALIA.] M. Péron says that the Tasmanian has a large head, especially remarkable for the great length of the line from the chin to the sinciput, and that the head of the New Hollander is less bulky, and is compressed in the back part, while that of the Tasmanian is elongated in

the same direction. The great difference consists in the hair, which is straight or curled in the New Hollander, and woolly in the Tasmanian. (*Papers on New South Wales*, by Baron Field, Esq.) In language and customs the resemblance is equally apparent. Tasman, in the brief account of his voyage, published in 'Harris's Collection of Voyages' (vol. i., p. 325), mentions his observing on the shores of Van Diemen's Land trees which had 'a kind of steps cut in the bark, in order to climb up to the birds' nests: these steps, he says, were the distance of five feet from each other, so that we must conclude, that either these people are of a prodigious size, or that they have some way of climbing trees that we are not used to.' The difficulty here suggested by Tasman has been since resolved: 'The natives of Australia climb trees by cutting notches in the bark, by means of a small stone hatchet, and with each hand alternately. By long acquired habit a native can support himself with his toes on very small notches, not only in climbing, but while he cuts other notches for his further ascent with one hand, the other arm embracing the tree.' (Major Mitchell's *Travels in Australia*, vol. ii., p. 338.) In this singular custom the natives of Van Diemen's Land and of Eastern Australia agree. The corroboreé dance [SWAN RIVER] is common to both, and the offensive weapons of both people are precisely the same. Major Mitchell expresses a decided opinion that the natives of both countries are derived from a common stock (*Travels*, vol. ii., p. 341), in which other travellers have concurred. The natives of Tasmania, according to the accounts of early colonists, and of Cook and D'Entrecasteaux, appear to have been more intelligent and friendly than those of New Holland when first approached. M. Labillardière, the historian and naturalist of the expedition of Admiral D'Entrecasteaux, speaks of their music, their knowledge of plants, and their general acuteness, in terms by no means contemptuous; while he highly praises the humane and confiding disposition which they evinced towards their French visitors. Dr. Ross, the Editor of the 'Van Diemen's Land Annual,' to whom we are indebted for the best records of the early history of the colony, after many years' opportunities of intercourse with the aborigines, thus refers to them: 'During all the intercourse I have had with this interesting people, I not only found no want of sense or judgment among them, but, on the contrary, much to admire in them as thinking men, as endued not only with much ingenuity and penetration, but with the tenderest sympathies of the heart, and all the nobler passions that elevate man in the scale of being.'

Original harmlessness of character has not however preserved the Tasmanians from the usual consequences of European contact—expatriation or extinction. The history of the events which have nearly extinguished this race is briefly as follows:—Van Diemen's Land was colonized in the first instance by the most abandoned criminals. These men had no wives; no regular system of discipline was adopted in reference to them, but they were dispersed in small bodies over the territory, while others, escaping from control, pursued a predatory life. The wives of the natives were seduced by criminals, which excited the animosity of the men, and during several years indiscriminate warfare subsisted between the aboriginal and the colonizing population. At length, in 1830, the local government systematically interfered, and the free and convict inhabitants of the colony were enrolled for the purpose of killing or capturing the aborigines. Very limited success attended this mode of proceeding after it had been in operation for a considerable period, when Mr. Robinson, an individual of remarkable courage and self-possession volunteered, with the assistance of some friendly natives, to bring the rest to terms of pacification. By fair promises to the natives he accomplished a victory which could not be obtained by an expenditure of upwards of 30,000*l*. (*Van Diemen's Land Annual for* 1838) differently directed, and the natives put themselves in the power of the government. This triumph, obtained by moral influence, and which might have been made subservient to the good of both races consistently with the aborigines remaining on their native soil, was converted to their ruin. They were transported to an unfavourable spot (Flinders' Island, in Bass's Straits), where a miserable remnant of about eighty individuals were all that survived in 1836 of a population of three or four thousands, the estimated aboriginal population of Van Diemen's Land when colonization began there. (*Van Diemen's Land Annual for* 1838, pp. 127-8.) The courage which faced the aborigines unarmed in a time of warfare, was no evidence that the individual who dared to do this possessed the qualities essential for the successful treatment of an uncivilized race with a view to its improvement. However that courage was rewarded by the appointment of Mr. Robinson to the office of 'civilizing' the Tasmanians at Flinders' Island. It would be tedious to detail the features of the 'civilizing' system pursued there: it is sufficient to mention that every habit and amusement peculiar to the aborigines has been discouraged; the cumbrous and uncongenial forms and incidents of advanced civilization have been enforced in every-day life; the native language has been as much as possible suppressed; native names have been made to yield to those of the Cæsars, the Hannibals, and the Scipios; a disposition to indulge in the pleasures of the chace has been recorded as a delinquency; and the verbal repetition of the Commandments and the Catechism is alleged as the evidence of religious progress, and a confutation of all disbelief as to the capacity of uncivilized races to appreciate the doctrines of Christianity. (*Report of the Commandant of Flinders' Island; Parliamentary Papers*, 1839.)

An intelligent witness of the experiment carried on at Flinders' Island has thus reported upon it: 'The commandant has an establishment of thirty-two convicts to wait on the aborigines, and supply the deficiencies of their own labour, and is rewarded by a great deal of reading, writing, singing, rehearsal of the catechism, tailoring, submission, attachment, decorum, tranquillity, everything, in a word, which gratifies superficial examination; and he persuades himself that he is eminently successful with them: but they have no free agency, and are mere children at school, and they cannot escape from their prison, they cannot subsist at a distance from it, they must not break its rules, it must be a place of excessive *ennui* to them: as moral agents they are lower now than when savages; and they die the faster, I fear, for much of this kindness. The commandant imputes the mortality among them to the situation and climate, and wishes to transport them to the south coast of New Holland; but in six months I am persuaded they would be, on this plan, happy savages in the bush.' (*MS. Letter.*)

TASSIE, JAMES, was born of humble parentage, in or about the year 1735, in the neighbourhood of Glasgow, and was brought up as a country stone-mason. Going to Glasgow on a fair-day to enjoy himself with his companions, he visited the collection of paintings exhibited by the brothers Foulis, who were then endeavouring to establish an academy for the fine arts in that city. [FOULIS, vol. x., p. 383.] Feeling a strong desire to become a painter, Tassie removed to Glasgow, and studied drawing in Foulis's academy, but continued to practise his business. Though poor, he was frugal, industrious, and persevering; and, hoping at least to become a statuary, if not a painter, he, in 1763, went to Dublin, where he was employed for some time as a sculptor and modeller. There he became acquainted with Dr. Quin, who was making experiments in the beautiful art of imitating engraved gems by means of coloured glass, or pastes, and who engaged him as his confidential assistant. Having succeeded in effecting great improvements in the art by their joint labours, Tassie was encouraged by his patron to remove to London, and to follow it as a profession. He accordingly reached London in 1766; and although, owing to his diffidence and modesty, he had to struggle with many difficulties, he gradually emerged from obscurity, obtained a comfortable competence, and established such a reputation, that the principal cabinets of Europe were thrown open to him. Among his earliest patrons in the metropolis were the Society of Arts, who, in 1767, awarded him the sum of ten guineas for imitations of antient onyx. In 1775 Tassie, who then resided in Compton Street, Soho, published a catalogue of the antient and modern gems in his collection, of which he sold pastes or sulphur impressions at very moderate prices. The collection then amounted to more than three thousand articles; but it was subsequently much extended, and in 1791 appeared a new catalogue, containing fifteen thousand eight hundred articles, and forming two quarto volumes. This work, which is not confined to a dry description of the gems, but contains

much useful information on that department of antient art, was compiled by Mr. R. E. Raspe, who prefixed to the catalogue an introduction on the utility of such a collection of works of art, and on the history of engraving upon hard stones, and the imitation of gems by artificial pastes. The work contains also a frontispiece and fifty-seven plates of gems, etched by David Allan. From Raspe's introduction it appears that the demand for Tassie's pastes was encouraged, in the first instance, by the jewellers, who introduced them into fashion by setting them in rings, seals, bracelets, and other trinkets. He was very careful of his reputation, and would not issue imperfect impressions; but the celebrity of his casts induced other and less skilful modellers to sell their works under his name. About 1787 or 1788 Tassie received an order from the empress of Russia for a complete set of his gems, which he executed in the most satisfactory manner, in a beautiful white enamel composition, so hard as to strike fire with steel, and of such a texture as to take a fine polish, and to show every touch of the artist with the greatest accuracy. Wherever it was possible to do so, he coloured these in exact imitation of the originals; and in other cases such colours were used as might display the work to advantage. Tassie's business was continued by his nephew, William, on his premises in Leicester-square; and he added to the collection a series of casts of coins, from the museum of the late Dr. William Hunter, of which he made a set by order of the emperor Alexander, to add to the gems executed for the empress by his uncle, who died in 1799. Besides the branch of art for which he is principally celebrated, Tassie displayed considerable talent in modelling small portraits in wax, from which he frequently made pastes. He was much respected in private life for his piety, simplicity, modesty, and benevolence.

(Raspe's *Catalogue of Tassie's Gems, &c.*; Dr. Gleig's *Supplement to the third edition of the Encyclopædia Britannica*, 1801.)

TASSISUDAN. [Bootan.]

TASSO, BERNARDO, born at Bergamo in 1493, lost his father when a boy, and was brought up under the care of his uncle Luigi Tasso, bishop of Recanati, who was living at Bergamo. The bishop being murdered by robbers in 1520, Tasso left his native town, and lived for several years at Padua and Venice, and other towns of North Italy, where he displayed his talent for poetical composition. In 1525 he engaged himself as secretary to Guido Rangone, who was general of the Papal troops in North Italy. In 1529 he went to the court of Ferrara, where he remained a short time. A volume of Italian verses which he published at Venice in 1531 made him known to Ferrante Sanseverino, prince of Salerno, one of the principal Neapolitan barons, who kept a princely court after the feudal fashion of the times. The prince invited him to come to Naples, granted him a handsome allowance, with the liberty of withdrawing himself from time to time from his court to apply to his poetical studies in rural retirement. Tasso accompanied the prince of Salerno in the expedition which Charles V. undertook against Tunis, in 1534. He was afterwards sent to Spain, in 1537, on a political mission, and on his return he spent some time at Venice, where he became acquainted with the celebrated Tullia d'Aragona, the illegitimate daughter of a cardinal of the royal house of Aragon, who was herself a poetess, and led a very free life. Bernardo Tasso wrote verses in her praise. Having at last disentangled himself from this connection, he returned to Naples, where he soon after married a young lady of Sorrento called Porzia de Rossi, by whom he had a son, Torquato. In 1547 an insurrection broke out at Naples against the Spanish viceroy Don Pedro de Toledo, who, in concert with Pope Paul III., wished to establish the Inquisition in Naples after the fashion of Spain. The people elected a sort of council composed of nobles and citizens, under the name of 'Union for the service of God, the emperor, and the city,' to administer temporarily the affairs of the country. This body chose the prince of Sanseverino and the prince of Sangro as its deputies to proceed to Germany and lay their grievances before Charles V. Bernardo Tasso, against the opinion of others, advised the prince to accept this mission. Sanseverino found the emperor highly incensed against the Neapolitans, and fearing for himself, he went to France and entered the service of Henry II., for which he was declared a rebel by Charles V., and his property was confiscated. Bernardo Tasso followed his patron to France, where, after a time, he found himself in great pecuniary distress. He then returned to Italy, and went to the court of Guidobaldo, duke of Urbino, from whence he passed to that of the duke Gonzaga of Mantua, who made him governor of Ostiglia, in which place he died in 1569.

Bernardo Tasso wrote a romantic poem in ottava rima, entitled 'Amadigi,' the subject of which is taken from a Spanish romance. [Amadis de Gaula.] The plot or plots of Tasso's poem are deficient in interest, but the style is good, and the poet excels in his descriptions and comparisons, but he indulges at times in licentious strains. After writing his poem, he detached one of the episodes and swelled it into a separate poem, entitled 'Floridante,' which was published after his death by his son. He also wrote five books of 'rime,' eclogues, hymns, odes, sonnets, and other lyrics, some of which are admired for their imagery and smoothness of versification. He introduced in the Italian language that species of poetry which is called 'pescatoria' and 'marinaresca,' being descriptive of the habits and occupations of fishermen and mariners. His letters have been published in three volumes.

(Corniani, *Secoli della Letteratura Italiana*; Tiraboschi, *Storia della Letteratura Italiana*; Panizzi, *Introductory Essay on the Romantic Narrative Poetry of the Italians*, prefixed to his edition of 'Bojardo.')

TASSO, TORQUA'TO, son of Bernardo, was born at Sorrento, in 1544. At the age of ten he was sent for by his father, then an exile, and after some time spent with him in several towns of north Italy, he went to the university of Padua to study law, for which however he had little inclination. At the age of eighteen he composed his first poem, 'Rinaldo,' in twelve cantos. The subject is romantic, and is taken from the old chivalric legends concerning Charlemagne and his wars with the Moors. Bernardo was at first angry with his son for neglecting his more serious studies, but at last he relented, and gave his consent to the publication of the poem, which Torquato dedicated to the Cardinal Luigi d'Este, brother of Alfonso II., duke of Ferrara. In 1566 the cardinal took him into his service as a gentleman attendant, and introduced him to his brother the duke, and to his two unmarried sisters Lucrezia and Eleonora. He was well received by all, and admitted into their familiar society. Tasso was young and amorous; he had been for some time passionately in love with Laura Peperara, a lady of Mantua, to whom he addressed many sonnets and other verses after the manner of Petrarch, styling her his Laura. This lady, with whom he had probably become acquainted during a visit which he paid to his father at Mantua in 1564, came some years after to Ferrara as a lady of honour of the duchess, and was married to Count Turchi of Ferrara. But in the mean time Tasso appears to have been struck with the personal attractions and mental accomplishments of the princess Eleonora, the duke's sister, and already in 1566 there is a sonnet by him, beginning 'Nel tuo petto real da voci sparte,' which is evidently addressed to a princess of a sovereign house. From that time he continued to write amatory verses evidently addressed to the same person, whom he styles his 'donna,' or mistress. In some of them he mentions the name of Eleonora, but as there were several ladies of that name at different times at the court of Ferrara, this has given rise to various surmises about the person meant. At last Tasso avowed in several ways his love for the princess, though, from the then existing usages of society, it was impossible that he could ever have obtained her hand. Most of the sonnets and other lyrics, which are evidently intended for this object of his second love, are conceived in a respectful and somewhat melancholy strain, as if the writer felt the hopelessness of his passion. The disparity of rank was in those times an insurmountable obstacle to any legitimate result of such an attachment, and the house of Este was one of the proudest in Italy. Like Petrarch, Tasso seems to have obtained friendship only in return for his love. But there are some of Tasso's compositions written between 1567 and 1570, in which he assumes the tone of a favoured lover. Such are the two sonnets 'Donna di me doppia vittoria aveste' and 'Prima colla beltà voi mi vinceste,' the dialogue between love and a lover, beginning 'Tu ch' i più chiusi affetti,' and the madrigal which begins 'Soavissimo bacio.' From the context, although no name is mentioned, they all evidently allude to the same object as the

other amatory verses addressed to his 'donna.' There are also some autograph lines of Tasso discovered by Mai among the Falconieri MSS., and published by Betti at Rome (*Giornale Arcadico*, October, 1827), in which Eleonora is mentioned by name:

'Quando sarà che d'Eleonora mia
Possa godermi in libertade amore?
Ah, pietoso il destin tanto mi dia!
Addio cetra, addio lauri, addio rossore.'

It would appear that these verses, having been abstracted from Tasso's papers by some enemy, and shown to Duke Alfonso, first roused his suspicions.

Professor Rosini, in his able essay upon the 'Love of Tasso and the Causes of his Imprisonment,' Pisa, 1832, proves, in opposition to the assertion of Serassi and others, that Eleonora d'Este was the object of the above compositions, as well as of all the others addressed to his 'donna.' It is the four compositions last alluded to that constitute the real guilt of Tasso: they boast in prurient language of favours received, which, according to the best circumstantial evidence, were never granted, and which, if even granted, ought not to have been mentioned. And Tasso himself must have felt this, for when he set out for France at the beginning of 1571, to accompany Cardinal Luigi d'Este on a mission to Charles IX., he left his MSS. in charge of his friend Rondinelli, with directions to publish them in case he should die abroad, 'except those which he had written to oblige some friend, and which must be buried with him.'

This was a subterfuge to conceal the object of the above-mentioned compositions, and to make them appear as if written at the request of others, which in itself would have been no very creditable employment for a man of genius. However, before the end of the year 1571, Tasso took his leave of the cardinal in France. It would appear that while in that country, where he was introduced at the court of king Charles IX., and became acquainted with the French poet Ronsard, Tasso applied himself to study the points of controversy then debated between the Roman Catholic and the Reformed churches, and that his investigations of those delicate matters displeased the cardinal, who spoke to him strongly on the subject. But Tasso had other and secret reasons for wishing to return to Italy. Having returned to Ferrara, he entered the service of Duke Alfonso himself, by whom he was most graciously treated. 'The duke extolled his poetical talent; he often listened to the recital of his verses (Tasso was then engaged about his 'Gerusalemme,' which he intended to dedicate to the duke); he admitted him to his own table, and to his own familiar society; and he refused him no favour that he chose to ask.' (Serassi, *Vita del Tasso;* Rosini, *Saggio sugli Amori di Tasso.*) Such was the conduct of Duke Alfonso towards the poet, until he discovered, years after, his guilty compositions. Whilst Tasso was thus a favoured guest, rather than a dependant of Duke Alfonso, he wrote his pastoral drama, the 'Aminta,' in which he portrays with exquisite skill the pangs and the delirium of love deemed hopeless for a long season, but in the end requited. The drama was performed at the court of duke Alfonso, and its fame soon spread about Italy. Lucrezia, Eleonora's sister, who had married Francesco Maria, duke of Urbino, wishing to hear the 'Aminta,' invited Tasso to her court, where he remained several months. This was in 1573. While Tasso was absent from Ferrara, envy was busy at work against him to lower his credit with Duke Alfonso. At the same time Guarino, the poet, who was also at the court of Ferrara, strove to ingratiate himself with the princess Eleonora, and this excited the jealousy of Tasso. It appears that Tasso had been in the habit of writing to the princess, and sending her some of his poetical compositions; but now he wrote none for several months. At last he wrote her a letter, dated September, 1573, which was first published by his biographer Serassi, in which, after apologizing for his long silence, he sends her a sonnet, 'which,' he says, 'is not like those fine ones which I suppose your grace is now wont to hear very often,' alluding to those of his rival Guarino. And he goes on to say, that his sonnet is poor both in the conception and the style, as the author is poor of luck. This last expression cannot be understood as referring to his circumstances, for he was still in favour with both the courts of Ferrara and Urbino, and was receiving at the time presents from the duchess Lucrezia of Urbino. But still he sends to the princess Eleonora the sonnet, 'hoping that, whether good or bad, it will produce the effect that he wishes.' This sonnet, which begins 'Sdegno, debil guerrier, campion audace,' is that of a desponding lover who asks for mercy. Tasso concludes his letter with the usual subterfuge, that 'the sonnet is not written on his own account, but at the request of a poor lover, who having been for a time angry with his mistress, is now no longer able to stand out, and surrenders himself and asks for mercy.' This and other passages of his amorous verses, referred to by Professor Rosini in the above-quoted essay, prove that the princess Eleonora had been long aware of Tasso's passion, and felt flattered by it, but probably looked upon it as a poetical feeling, for which she gave him her friendship. He himself acknowledges this in several places; and yet this same man had already written, in the recess of his study, the guilty compositions which have been mentioned above.

Towards the end of 1573 Tasso returned to Ferrara, where he applied himself to finish his great epic poem 'La Gerusalemme.' The touching episode of Olindo and Sofronia, in the second canto, was meant to portray his own situation with regard to the princess Eleonora; and in a sonnet which he wrote to that lady he evidently speaks of the character of Sofronia as meant to represent herself.

Parts of the 'Gerusalemme' began to circulate about in MS., and the author was assailed by numerous pedantic critics. He thought that the duke and his sister Eleonora did not take up his defence with sufficient zeal; and this slight sank deep into the poet's heart. Towards the end of 1576 a false friend, who was in the secret of his love for the princess, disclosed some particulars of it to others. Tasso having heard of this, and meeting him in the court of the ducal palace, required him to deny what he had said, and upon the other's refusal, gave him a blow in the face. This led to a duel; the treacherous friend came escorted by his relatives, who also drew their swords against the poet, but Tasso, who was a good swordsman, succeeded in parrying their blows, and came away in triumph. Nothing particular happened after this until June of the following year, 1577, when Tasso, on the evening of the 17th of June, being in the apartments of the duchess of Urbino, in Duke Alfonso's palace at Ferrara, fell into a violent passion at some impertinence real or supposed of a domestic, and forgot himself so far as to throw a knife after him. He was immediately arrested by order of duke Alfonso, and confined to a room which looked on the court of the palace. It appears that between these two incidents his own servants had been tampered with in order to give up his concealed papers. Tasso got information of this, and looked out for a trusty servant from Urbino, and wrote on the subject to Guido Baldo, marquis del Monte, and his letter is quoted by his biographer Serassi. He had also felt for some time scruples about matters of faith: he mentions in his discourse to Scipione Gonzaga, that he had doubts concerning many points of religion; he had even applied to the inquisitor of Bologna, who had granted him absolution; but still he thought himself under the censures of the church. All these things added to the anguish of his mind. From the place of his imprisonment Tasso wrote a submissive letter to the duke, begging his pardon, and the duke appearing to forgive him, released him after a few days, and took him with him to his country-seat of Bel Riguardo about the end of June. What happened there between the duke and Tasso is not ascertained, but from some expressions of the poet it appears that he was there closely and sternly examined by the duke, who had probably by this time in his possession Tasso's papers, 'in order to get from him an acknowledgment of what, if avowed, would incense him against him.' (Tasso's Sonnet, beginning 'Alma grande d'Alcide,' addressed to the deceased duke Hercules, father of Alfonso.) On the 11th of July the duke sent Tasso back to Ferrara under an escort, and shut him up in the convent of St. Francis, his secretary having written to the monks that he was mad, and must be treated as a madman.

Tasso's love adventures, his real or pretended madness, and the causes of his long imprisonment, made much noise about Italy at the time; and they have been so much discussed and commented upon since, that they have acquired an historical importance, especially as they serve to illustrate the manners of the times. Duke Alfonso has been much abused, and, we think, without discrimination, for his treatment of the poet. There is a

mystery about the whole story resembling that which hangs over Ovid's banishment. Professor Rosini has collected with the greatest patience and care the discordant opinions, as well as the evidence resulting from Tasso's own writings, published and unpublished, and from those of his contemporaries; and the conclusion which he arrives at by the help of sound criticism is, that the Duke, having in his hands the loose compositions of Tasso already mentioned, which joined to his other compositions addressed to the same person, and his other strange sayings and doings, furnished full evidence that his sister Eleonora was the person alluded to in them, was naturally enough incensed against the poet, and thought that the only reparation that he could make to her injured honour was to make it be supposed that Tasso was mad. This gives the clue to his subsequent treatment of the poet. He must also have been confident that his sister was guiltless, otherwise, as Rosini observes, he would have taken a different sort of vengeance, according to the manners of the age. From the convent of St. Francis, Tasso wrote to the duke, saying, 'that the clemency of his highness had forgiven him his faults, and that thenceforth if he spoke to any one, he should acknowledge to all that which he clearly knew, that he was under a sanitary treatment.' He adds, that he had resolved, when the treatment was over, to turn monk; and in a postscript he says, that he earnestly wishes that the Duke may know all the truth, that he may not think him more mad than he is. In a long letter which he afterwards wrote to the Duke of Urbino, he says, that 'in order to please Duke Alfonso, he thought it no disgrace to imitate the example of Brutus and Solon.' Both those personages, according to Livy and Plutarch, feigned madness. Receiving no answer from either Duke Alfonso or the Duke of Urbino, Tasso, about the 20th of July, ran away from the convent, quitted Ferrara, and made his way alone and mostly on foot to Naples, and thence to Sorrento, where his sister was married. Having by kind treatment recovered his health and his spirits, he went to Rome, where he applied through some agent of the Duke to be allowed to return to Ferrara. Duke Alfonso wrote in reply, that he was willing to receive Tasso again into his service, if he would allow himself to be treated by the physicians; but that if he continued his subterfuges, and to talk as he had done before, he would immediately turn him out of his territories, and never allow him to return. Tasso, upon this, returned to Ferrara in the spring of 1578, with the Cavaliere Gualengo. He was civilly but coldly received by the Duke, who gave him to understand that he ought now to try to compose himself and to lead a quiet life, and to avoid all excitement. He attempted to get an interview with the Princess Eleonora and the Duchess of Urbino, but was prevented. Tasso, tired of this manner of life, having lost the favour which he used to enjoy at court, ran away again from Ferrara in the summer of 1578, wandered to Mantua, Padua, and Venice, and then went to Urbino, where he wrote to the duke of Urbino, who appears to have been then on bad terms with his own wife and with the court of Ferrara, entreating him to make the truth known, and to contradict the reports maliciously 'circulated of his madness,' saying that he had submitted to it in obedience to Duke Alfonso's wishes, but that he could not consent any longer to lead an animal life, far from literature and from the Muses. He wrote in similar terms to his friend Scipione Gonzaga at Rome, to his own sister at Sorrento, and to the Arciprete Lamberti, to whom he sent a sonnet, beginning 'Falso è il romor che suona.' In October, 1578, he left Urbino, and went to Piedmont under an assumed name; but he was soon known, and his fame as a poet secured him a flattering reception from Charles Emmanuel, Prince of Piedmont, who offered to take him into his service upon the same terms as the Duke of Ferrara. But poor Tasso had still his eyes and his heart fixed upon Ferrara, and in spite of the advice of his friends at Turin, and, among others, of the Marquis Filippo d'Este, Alfonso's relative, he determined to go to Ferrara. He was encouraged to do so by letters from the Cardinal Albano, who it appears had been commissioned by the duke to induce him to return, promising him a kind reception. He arrived at Ferrara on the 21st February, 1579, on the eve of the arrival of Margarita Gonzaga, the new bride of Duke Alfonso. The court was busy about the preparations to receive the duchess. The duke refused to see Tasso, the princesses also denied themselves, his old apartments in the palace were closed to him, and the courtiers and court attendants treated him with rudeness and contempt. Tasso now became furious, and he uttered impertinent words against the duke and the whole house of Este, which being reported to Alfonso, he gave orders to arrest him and confine him in the hospital of St. Anna as a declared madman.

Tasso remained a prisoner in the hospital full seven years, till July, 1586. From some obscure passages of his own letters he appears to have been treated very harshly at first by the attendants of the hospital. He wrote to the duke, and to the princesses, but in vain. At last he grew more calm, and was treated with greater leniency. The wretched hole which is shown at Ferrara as having been his prison is no longer believed by competent judges to be the identical place of his confinement. (Valéry, *Voyages Littéraires en Italie*, book vii., ch. 14.) Political party-feeling in our age has contributed to exaggerate the hardships of Tasso's confinement, as religious party-feeling has exaggerated the sufferings of Galileo in a similar condition. There was hardship no doubt in both instances, and the hardship in Tasso's case was aggravated by the state of his own sore and unsettled mind. When Cardinal Scipione Gonzaga visited Tasso at St. Anna, in the spring of 1580, he was lodged in a large and commodious apartment, where he could write and correct his compositions. In November of the same year he was visited by Montaigne, who speaks of him as a man whose reason was overcome by the vivacity of his imagination. In July, 1581, the Lady Marfisa d'Este obtained leave of Alfonso to take Tasso with her for a few days to her country-house, where he had a philosophical discussion with her and her two ladies of honour, Tarquinia Molza, a learned woman, and Ginevra Marzia, upon the nature of love. From the recollection of this conversation, Tasso afterwards composed his dialogue, which he entitled 'La Molza, ovvero dell' Amore.' In September, 1582, Tasso received at St. Anna the visit of Aldo the younger, who brought him copies of some of the finest editions which had come out of his press, and they spent two days together in speaking of their respective studies. Tasso in the meantime was busy writing, or correcting his various poetical compositions which were printed at Venice, but very inaccurately, to his great annoyance. He wrote in his confinement several philosophical discourses or treatises, such as 'Il Gonzaga, ossia del Piacere Onesto,' 'Il Padre di Famiglia,' the discourse 'Della Virtù Eroica e della Carità,' the dialogue 'Della Nobiltà,' and others. In his discourse to Gonzaga he says that it was wished that he should become insane, and that the cause, or at least one of the causes, of this persecution was some lascivious verses of his.

In 1583 Tasso grew seriously ill, he complained of his head, of his digestion, of singing in his ears, and other symptoms of a like nature. He consulted his friend Mercuriale, a physician of Padua, but Tasso was not a very docile patient; he wished for none but pleasant medicaments, and he would not submit to a total abstinence from wine. One of his vagaries was that he had a familiar spirit who appeared to him to comfort him. In 1584 he was allowed to be out at large during the Carnival season, and he wrote a curious dialogue on that circumstance entitled 'Il Gianluca, o della Maschere.' He enjoyed the society of Tarquinia Molza, of Count Girolamo Pepoli, and other noblemen and ladies of the court of Ferrara. He wrote about that time the dialogues 'Il Beltramo, ovvero della Cortesia;' 'Il Malpiglio, ovvero della Corte;' 'Il Ghirlinsone, ovvero dell' Epitaffio;' 'La Cavalletta, ovvero della Poesia Toscana;' and 'Il Rangone, ovvero della Pace,' which last, addressed to Bianca Capello, grand-duchess of Tuscany, is dated from his apartments of St. Anna, 'Dalle sue stanze in St. Anna.' He was now tolerably composed and reconciled, and could hardly be called a prisoner. In one of his autograph letters, written to the Marquis Buoncompagni, in April, 1585, and which is in the library of Ferrara, there is a passage copied by Valéry, in which he says that 'the duke does not keep me in prison, but in the hospital of St. Anna, where priests and monks can visit me at their pleasure, and no one prevents them from doing me good.' In several of his unpublished letters he gives directions about some articles for his wardrobe or his table, and shows a refined taste in both. But

in that same year, 1585, a fresh source of vexations opened upon him. His great epic poem, 'La Gerusalemme Liberata,' had been published complete at Parma in 1581, and afterwards at Mantua in 1584. A host of critics fell upon it, and by their strictures strove to obscure all the merits of the poem. At the head of them stood Salviati, of the Crusca Academy. Tasso's language, his poetical style, his imagery, the plot of his poem, his episodes, everything was made a subject of censure. Tasso, already weakened by mental and bodily suffering, felt these attacks bitterly. He however took up his pen and wrote in a measured and dignified tone a defence of his poem. He was at the same time writing letters to all his friends to obtain his final liberty from the duke. He wrote to the city of Bergamo, to the duke of Mantua, to the grand-duke of Tuscany, to the pope, to the emperor, who all employed their good offices on his behalf with Duke Alfonso, who hesitated a long time before he consented to his release. At last Vincenzo Gonzaga, son of the duke of Mantua, obtained, in July, 1586, permission for Tasso to accompany him to Mantua. His reception at that court was like a triumph. In order to make some return for the kindness which he experienced from the house of Gonzaga, he completed his tragedy of 'Torrismondo,' which he dedicated to his liberator Vincenzo, on his accession to the ducal throne of Mantua in 1587. The subject of the 'Torrismondo' is a supposed Scandinavian legend. Some of the descriptions have been admired. After some time spent at Mantua and in his paternal town of Bergamo, Tasso, depressed by a settled melancholy, took leave of Duke Vincenzo, and repaired to Rome in the latter part of 1587, and thence to Naples in the following year. The poet appeared delighted with the beauties of his native country. At Naples he began a lawsuit to recover his paternal property, which had been seized when his father Bernardo became an exile. The Neapolitan courts of law have been at all times proverbially known for their dilatoriness, and justice was wretchedly administered under the Spanish viceregal administration. Tasso made little progress in his suit. But he found a sincere friend in the Marquis Gio. Batista Manso, who took him in the autumn to his estate of Bisaccio, where they spent the time in sporting, listening to the rustic improvvisatori, and conversing in the evening upon various topics, especially about Tasso's pretended familiar. It was at the request of Manso's mother that Tasso undertook his 'Sette Giornate del Mondo Creato,' which is a poetical paraphrase of the narrative of the creation of the world in the first two chapters of Genesis. In 1589, Tasso, always restless, repaired to Rome; but finding himself in great pecuniary distress, he accepted an invitation of the grand-duke Ferdinand de' Medici to go to Florence in the spring of 1590, where he was received with great honour by the court and other persons of distinction, as if to make amends for the annoyance given to him by Salviati and his compeers.

Towards the end of the same year however he went to Rome, and in 1591 he returned to Naples, and then applied himself to re-write his epic poem, under the title of 'Gerusalemme Conquistata,' in order to satisfy the critics. However the first version of his poem is in the hands of all, whilst few ever read his 'Gerusalemme Conquistata.' Tasso intended to end his days at Naples; but in 1592, Cardinal Aldobrandini having been made pope by the name of Clement VIII., his nephew, Cinzio Aldobrandini, afterwards cardinal, who was well acquainted with Tasso, invited him in the most pressing manner to Rome, where he came about middle of that year. He was stopped several days at Mola di Gaeta, the road being blocked up by the bands of the famous robber chief Marco Sciarra, who was scouring the country with perfect impunity. Sciarra, who was a man of birth and education, having heard that Tasso was detained at Mola, sent him a message to entreat him to proceed on his journey, assuring him of perfect safety from his men, and offering him an escort, which however Tasso declined; upon which Sciarra withdrew his men from the mountains of Itri, so as to leave the passage open for Tasso. Having arrived safely at Rome, he completed his 'Gerusalemme Conquistata,' which he dedicated to Cardinal Cinzio Aldobrandini. In the summer of 1594 he returned to Naples, and lodged first in the Benedictine monastery of San Severino, and afterwards went to a country-seat of his friend Manso. Meantime Cardinal Cinzio, out of affection and gratitude towards Tasso, prevailed on Pope Clement to grant the poet the honour of being solemnly crowned with the laurel-crown in the Capitol, as Petrarch and others had been. This being agreed upon, Cardinal Cinzio hastened to announce the news to Tasso, urging him to repair to Rome as soon as possible. Tasso did not seem at all elated: he observed to Manso that he thought it more glorious to deserve honours than to receive them. He however assented, and took an affectionate leave of his kind friend Manso, with a foreboding that it would be the last. He spent the Christmas festivities at the monastery of Monte Casino, and arrived at Rome in the beginning of 1595. He was met outside of the gates by many gentlemen and attendants of the Papal court, by whom he was led in a kind of triumph to the Vatican palace, where he was introduced to the pope, who told him that he had 'awarded him the laurel-crown, in order that it might be as much honoured by him, as in former times it had served to honour others.' Tasso was lodged in the Papal palace, and treated with the greatest regard. While the day of the coronation was anxiously expected, Cardinal Cinzio fell ill; and Lent coming on, the pageant was postponed, and then Tasso himself fell seriously ill. He felt from the first a conviction that this illness would be his last; and wishing to compose himself in retirement for his last moments, he expressed a wish to be taken to the monastery of St. Onofrio, on Mount Janiculum. Having been carried thither in one of Cardinal Cinzio's carriages, he said to the prior and his monks who came to receive him at the gate, 'I am come to die amongst you.' He was led into a comfortable apartment, where he devoted his remaining days entirely to religious practices, and seemed totally weaned from worldly feelings and cares. When the pope's physician announced to him his approaching death, he embraced him, thanking him for the happy tidings. To Cardinal Cinzio, who came to take leave of him, he expressed his gratitude for all his kindness; and as the cardinal and those present could not refrain from tears, he said to them, 'You think that you are leaving me, but I shall go before you.' He expired on the 25th of April, 1595, after fifteen days' illness, being fifty-one years of age. He was buried, according to his desire, in the church of St. Onofrio, with a plain slab over his tomb, upon which the monks engraved the simple inscription, 'Torquati Tassi ossa hic jacent.'

The lasting fame of Tasso as a great poet rests upon his 'Gerusalemme Liberata,' or 'Il Goffredo,' as it is sometimes called, one of the few great epic poems of which the world can boast. The action is complete: it relates the events of the great crusade, and ends with the ostensible object of that expedition, the deliverance of Jerusalem from the hands of the Moslems. The beauties, as well as the faults of the composition, have been the theme of many disquisitions. Among foreign critics, Blair, Voltaire, D'Alembert, La Harpe, and Châteaubriand have been loud in its praise. The poem has a peculiarity that distinguishes it from most other epics: it is essentially a Christian poem; and breathes throughout the feelings, the faith, and the hopes of a Christian. Tasso, as he says in his invocation,

> 'O Musa, tu che di caduchi allori
> Non circondi la fronte in Elicona,
> Ma su nel Cielo infra i beati cori
> Hai di stelle immortali aurea Corona.'—(c. i., st. 2.)

had drawn his inspiration from a sacred source, and has thus afforded a refutation to those who pretend that the Christian religion is not so favourable to poetical imagery as the splendid fictions of mythology. A melancholy tinge pervades the poem; but it is a melancholy lighted up by cheering and constant hope. With the single exception of the episode of the gardens of Armida, the language of the 'Gerusalemme' is eminently chaste, and the morality of its sentiments is pure and elevated, which renders it fit for the perusal of youth. Among its beauties of detail we will only instance the episode of Olindo and Sofronia, in the 2nd canto; the council of the dæmons, in the 4th; the flight of Erminia, and her meeting with the old shepherd on the banks of the Jordan, in the 7th; the introduction of the Turk Solyman into the besieged city, in the 10th; the death of Clorinda, in the 12th; and the last fight of Argante with Tancred, in the 19th canto.

The other poems of Tasso have been mentioned in the course of this article. His lyrical compositions are very

numerous, and many of them exquisite both in language and sentiment. Besides those which are upon amorous subjects, some refer to contemporary events, or are in praise of contemporary princes; others are upon religious subjects; and others refer to his own misfortunes. The whole of Tasso's poetical works have been published in one large 8vo. vol. of nearly 1000 pages, in double columns, at Venice, 1833. Prefixed to it is the biography of the author, by his friend the Marquis Manso.

Tasso's prose works consist of dialogues and dissertations, some of which have been already noticed; of a treatise upon epic poetry, dedicated to Cardinal Pietro Aldobrandini; discourses upon the poetical art, dedicated to Scipione Gonzaga; and of numerous letters, some of which have remained unpublished till lately, 'Lettere Inedite,' Pisa, 1827. Professor Rosini has edited a new edition of all the works of Tasso, begun at Pisa in 1820.

Tasso's 'Gerusalemme Liberata' has been translated into most European languages. There are English translations by Fairfax, Hoole, Broadhead, Hunt, and Wiffen. It has also been paraphrased into several Italian dialects, Milanese, Neapolitan, Calabrian, &c. The Life of Tasso has been written by Manso, Serassi, and others, and has been commented upon by Tiraboschi, Muratori, Zeno, Maffei, and other Italian philologists.

TASSO'NI, ALESSA'NDRO, born of a noble family at Modena, in 1565, was educated first in his native town, and afterwards at Bologna and Ferrara, where he studied the law. In 1597 he went to Rome, when he entered the service of Cardinal Aseanio Colonna, whom he accompanied to Spain in the year 1600. In 1603 the cardinal, having been made viceroy of Aragon, sent Tassoni to Rome to take charge of the administration of his property in Italy. During his stay in Spain Tassoni had opportunities of observing the internal state of that kingdom, which, after alarming all Europe in the preceding century by its ambition and the extent of its conquests, was now fast sinking into decay under the weak reign of Philip III. At Rome he wrote his 'Considerazioni sopra il Petrarca,' published in 1609, in which he commented very severely upon numerous faults, real or supposed, which he pointed out in the writings of that generally admired poet. Endowed with an inquisitive but somewhat captious mind, Tassoni aimed in his writings at opposing received opinions, and he employed sarcasm and ridicule for the purpose. Aromatari of Assisi took up the defence of Petrarch in his 'Risposte' to Tassoni's considerations, and this led to a controversy in the usual bitter style of Italian literary polemics. In 1612 Tassoni published his 'Pensieri Diversi' in ten books, being a collection of remarks on various subjects of science and literature which he had been in the habit for years of entering in his memorandum-book. Among other subjects he attacked the Physics of Aristotle, although he does not seem to have had himself very correct notions of physical phenomena. This work led to another controversy between Tassoni and several of his contemporaries. Meantime the Cardinal Colonna had died, and Tassoni, being now without employment, applied to Charles Emmanuel I., duke of Savoy, who promised him the post of secretary to his son, the cardinal of Savoy. But partly through court intrigues, and partly on account of Tassoni's known aversion to the court of Spain, with which the Duke of Saxony wished to be on good terms, he was kept waiting for years before he could take possession of his office at the court of the cardinal, who was then residing at Rome. Certain compositions entitled 'Filippiche,' in which the court of Spain was severely handled, as well as another pamphlet entitled 'Esequie della Monarchia di Spagna,' which appeared during that period, were generally attributed to Tassoni. Tiraboschi thinks that the first two of the 'Filippiche' are Tassoni's, but that the other five are by another pen. Copies of this work are very scarce. In 1623 Tassoni left the cardinal of Savoy in disgust, and retired to a country-house in the suburb of Transtevere, where he employed himself in study and rural occupations. About this time he had his portrait taken with the rind of a fig in his hand and the following distich written underneath:—

'Dextera cur ficum quæris mea gestet Iunonem?
Longi operis merces hæc fuit: aula dedit.'

In 1626 Cardinal Ludovisi, nephew of Pope Gregory XV., took Tassoni into his service, and gave him apartments in his own palace, with a handsome stipend. After the cardinal's death, in 1632, Tassoni repaired to Modena, when he was made counsellor to his sovereign Duke Francis I. of Este, for the remainder of his life. He died at Modena in 1635.

Besides the works already mentioned, Tassoni made an abridgment in Italian of the 'Annals' of Baronius, and some 'Annotazioni,' or corrections and additions to the Italian vocabulary of La Crusca. But the work for which he is best known is his mock-heroic poem, 'La Secchia Rapita,' or the 'Rape of a Bucket.' He is considered as having first introduced this kind of composition in the Italian language, as he had finished, though not published in print, his poem years before his contemporary Bracciolini published, in 1618, his 'Scherno degli Dei,' in which he turns into ridicule the gods of the antient mythology. Tassoni's poem was published in a printed form in 1622, but MS. copies had been in circulation long before. The subject is taken from the annals of his country under the year 1249, when a war having broken out between the two neighbouring cities of Modena and Bologna, the Modenese carried off in triumph a wooden bucket from within one of the gates of Bologna, which bucket is still seen suspended by a chain in the cathedral of Modena. The 'Secchia Rapita' has been generally admired by Italian as well as foreign critics. Voltaire speaks of it disparagingly, although he has borrowed from it (Valéry, *Voyages Littéraires*), but Perrault and other French critics have done Tassoni full justice. The humour of the poem is peculiarly Italian, and the admixture of the serious and heroic with the burlesque is happily combined. Some of the descriptive passages are exquisitely soft and true to nature, such as the song in canto viii. which begins: 'Dormiva Endimion tra l'erbe e i fiori,' and the beautiful episode in canto x. of the voyage of Venus from the mouth of the Arno to Naples for the purpose of engaging Manfred, son of Frederic II., to assist the Guibelines of North Italy. The 'Secchia Rapita' has gone through numerous editions: that of Barotti, Modena, 1744, is most splendid. Gironi has collected various judgments and comments upon this poem in his biography of Tassoni. Muratori has also written the Life of Tassoni.

(Tiraboschi, *Storia della Letteratura Italiana;* Corniani, *Secoli della Letteratura Italiana;* Zeno, *Note al Fontanini.*)

TASTE. The organs of this special sense are certain parts within the cavity of the mouth, obviously so disposed as to take early cognizance of matters about to be swallowed, and to act as sentinels for the remainder of the alimentary canal, at the entrance of which they are situated. Their special endowment, aided by an exquisite development of common sensibility, enables them to give timely notice of any acrid, caustic, or nauseous quality, of any undue temperature, of any inconvenient hardness, irregularity, size, or sharpness in the material submitted to them, and thus to protect the stomach against the intrusion of many hurtful agents. These organs moreover establish for our appetites a scale of liking and disliking: they superadd a discriminative pleasure to the enforced assuaging of hunger: they modify that merely quantitative ingestion, which is an absolute and daily need of the organism, with a qualitative choice, and so give a motive to those variations in diet which experience proves to be beneficial or necessary.

Common language (as in the word 'palatable') seems to attribute the sense exclusively to a part, which is by no means the only or chief seat of it. In order to give a more correct notion of its extent, we shall first briefly sketch the arrangement of the membrane which lines the cavity of the mouth. It is a continuation (a tubular folding in, as it were, through the aperture of the lips) of the general integument, the skin; and although somewhat changed in its grosser characters, it yet preserves, under the name of mucous membrane, a close resemblance to the parent tissue. It lines the inside of the cheeks, invests the alveoli, or gums, giving to these parts their polished smoothness of surface, is reflected from the lower alveolar arches to the tongue, from the upper alveolar arches to the palate, and from both these organs prolonged backward into the throat. In its palatine portion, the membrane covers the horizontal processes of the upper jaw, which divide the cavity of the mouth from that of the nose, and, while spread on this solid frame-work, is said to belong to the hard palate; and it likewise extends backward, beyond the limits of this bony partition, to form a pendulous flap, called the soft

palate; which, with the nipple-like uvula, that hangs from its extreme edge, may readily be seen when the mouth is opened. In extending to the tongue, the membrane is so arranged as to leave the tip and sides of that organ prominent and free; and is remarkably developed into a vast number of minute eminences called *papillæ*, which cover the borders and surface of the tongue, are largely supplied with nerves and blood-vessels, and variously concerned in the functions of the part. [Tongue; Palate.]

Very careful experiments on the sense of taste have been made by MM. Guyot and Admyrauld (*Mémoire sur le Siège du Goût chez l'Homme*, Paris, 1830), from which the following results are obtained:—A small portion of the soft palate, just above the base of the uvula, the remotest part of the back of the tongue, where it corresponds to the isthmus of the palate, and the entire circumference of the tongue, are so endowed; while the internal surface of the cheeks, the hard palate, the gum, the remaining parts of the soft palate and of the tongue are entirely destitute. Thus, those parts of the tongue with which, in sipping or in masticating, the food would have contact (its borders, and, most eminently, its tip), are gustative; and the property is shared, though in a less degree, by the lingual and palatine surfaces of the isthmus through which the food enters the sphere of involuntary actions.

The nerve, specially endowed with the sense of taste, is a branch of the third part of the fifth cerebral nerve, called, from its function, gustatory; but it seems possible to some physiologists that the glosso-pharyngeal nerve shares this property. The gustatory nerve is distributed to the papillary surface of the tongue, especially along its borders and tip: the lingual part of the glosso-pharyngeal nerve is restricted in its distribution to the posterior part of the tongue, where it supplies the mucous surface exclusively.

For the sensation of taste, moisture must be present; all are familiar with a temporary impairment of the sense, under the influence of unusual dryness of the surface of its organs; the parched tongue of fever is notoriously indifferent to all savours. Matters are only capable of being tasted when they exist in a fluid form: an insoluble body is insipid; a solid body provokes an immediate flow of saliva, and its sapid qualities are perceived in proportion only as it dissolves: certain gases are alleged to excite sensations of taste; but it is only by such as are soluble in the saliva (sulphurous acid, for instance), and only in proportion as they are dissolved that these impressions are produced.

'"The sensation of taste undoubtedly admits of an immense variety of modifications which no language can express. If a man were to examine five hundred different wines, he would hardly find two of them that had precisely the same taste: the same thing holds in cheese, and in many other things. Yet of five hundred different tastes in cheese or wine, we can hardly describe twenty, so as to give a distinct notion of them to one who had not tasted them."' The vague, or not-to-be-described, nature of gustatory impressions, as here expressed by Dr. Reid, receives some additional obscurity from the circumstance that taste and smell are often simultaneously affected in a manner which renders it difficult to abstract either. Various substances, after exciting the sense of touch on the fauces, and that of taste on the tongue, are capable of producing a third impression, which is popularly referred to the palate, but is really felt upon the sentient membrane of the nostrils: the fume of certain kinds of food ascends into the cavities of the nose, and produces this third and distinct sensation: in administering medicine to children, it is well known that the greater part of what is disagreeable in its flavour may be avoided by closing the nostrils when the draught is swallowed; and by repeating this experiment upon various articles of food, it is easy to ascertain how much of their flavour depends upon one sense, and how much is appreciated by the other.' Mr. Mayo, from whom this paragraph is quoted, goes on to classify the impressions produced by substances taken into the fauces:—

1. Where sensations of *touch* alone are produced, as by rock-crystal, sapphire, or ice.

2. Where, in addition to being felt upon the tongue, the substance excites *sensation in the nostrils*, as for instance tin and other odorous metals.

3. Where, besides being felt upon the tongue, it produces sensations of *taste*, as, for instance, sugar and salt.

4. Where the substance is felt on the tongue and tasted by it, and in addition excites a sense of flavour in the nostrils, as, for instance, bread, manna, and other substances. (*Outlines of Physiology*, p. 314.)

Flavour, then (in distinction from *taste*), can in correctness be attributed only to bodies possessed of some aroma or volatility; and, by alternately smelling and tasting such, and by contrasting their impression with that produced by a simply sapid substance (mustard and salt can illustrate the two cases), it will be noticed that flavour is but an odour, which, from its affecting a comparatively unpractised part of the olfactory apparatus, is at first imperfectly and obscurely recognised.

Such are the chief relations of the sense of taste in man, and in the animals which most nearly resemble him in structure. As the sense is a provision for the security of the digestive organs, we may on sound physiological grounds anticipate its existence, under a more or less modified form, in every animal possessing a digestive cavity. No special organ for its exercise (with very doubtful exceptions) can be traced in the invertebrata; nor can we presume to infer in them the presence of taste, otherwise than as an obscure sense determining their choice or rejection of food: to this extent it undoubtedly exists in them, even to the bottom of the scale—to the infusory animalcules, in which Ehrenberg has witnessed its exercise. Among the invertebrata, mollusks possess the most highly developed alimentary organs, and it seems probable that in them the guiding sense of those organs has a corresponding development.

Through the subregnum of vertebrata it acquires an advancing maturement: in the lower classes, fishes and reptiles, the organs are present, but seem rather to belong to the movements of prehension and of deglutition, than to the sense of taste: in birds too the organs are little developed, and the sense seemingly imperfect: through the class of mammalia it is gradually augmented in acuteness; but although in certain orders of them, or in particular individuals, the sense appears sharp and the appetite fastidious, it is probably in man alone that the organs and their function are completely matured.

TASTE, according to the definition of Sir Joshua Reynolds, 'is that act of the mind by which we like or dislike, whatever be the subject.' (*Discourses before the Royal Society*; Discourse vii.)

Taste is frequently spoken of as a gift, as something independent of rules, a kind of instinct, bestowed more liberally in degree upon some men than upon others. It has been treated by some writers as the result of caprice or fashion, as having no uniform or permanent principles for the ground of its decisions. Others have resolved it into different complex elements, whose joint development is determined by certain principles of beauty or sublimity in things external.

Lord Bacon has been quoted as apparently sanctioning the idea of taste being a kind of gift or instinct. 'A man cannot tell,' he says, 'whether Apelles or Albert Durer were more the trifler; whereof one would make a personage of geometrical proportions; the other by taking the best parts out of divers faces to make one excellent. The painter must do it by a kind of felicity, and not by rule.' Sir Joshua Reynolds has overthrown this position in one sentence: 'Every object which pleases must give us pleasure upon some certain principles.' These principles are unquestionably so intelligible that they may be embodied in the form of words, and may be drawn out into rules. Burke, towards the end of his essay on Taste (introductory to the Sublime and Beautiful), has likewise adverted to this position, which will come under notice again in the course of this article.

The hypothesis which refers our emotion of taste to the influence of fashion, or temporary and varying causes, has been maintained in the *Inquiry into the Principles of Taste*, by Mr. Payne Knight. According to Mr. Knight, there is scarcely any subject upon which men differ more than concerning the objects of their pleasures and amusements; and this difference subsists not only among individuals, but among ages and nations; almost every generation accusing that which preceded it of bad taste in building, furniture, and dress; and almost every nation having its own peculiar modes and ideas of excellence in these matters, to which it pertinaciously adheres, until one particular people has acquired such an ascendency in power and reputation as to set what is called the fashion, when this

fashion is indiscriminately adopted upon the blind principle of imitation, and without any consideration of the differences of climate, constitution, or habits of life, and every one who presumes to deviate from it is thought an odd mortal, a humorist void of all just feeling, taste, or elegance. The fashion continues in the full exercise of its tyranny for a few years or months, when another, perhaps still more whimsical and unmeaning, starts into being and deposes it; all are then instantly astonished that they could ever have been pleased even for a moment with anything so tasteless, barbarous, and absurd. The revolutions in dress only, not to mention those in building, furnishing, gardening, &c., which have taken place within the last two centuries afford ample illustration. . . . . ' Let no one imagine,' says Mr. Knight, ' that he solves the question by saying that there have been errors in taste, as there have been in religion and philosophy; for the cases are totally different: religion and philosophy being matter of belief, reason, and opinion; but taste being a matter of feeling, so that whatever was really and considerately thought to be ornamental must have been previously felt to be so; and though opinions may by argument or demonstration be proved to be wrong, how shall an individual pretend to prove the feelings of a whole age or nation wrong, when the only just criterion he can apply to ascertain the rectitude of his own is their congruity with those of the generality of his species.' (c. i., p. 1.)

This argument is founded on an exaggeration of a fact in reference to the philosophy of taste admitted by those who contend that taste is determined by some definite and invariable principles: the fact may be described under the general head of the influence of association on our emotions of this order. Mr. Dugald Stewart has observed on the exaggeration in question, that the association of ideas can never account for the origin of a new notion, or of a pleasure essentially different from all the others which we know. It may indeed enable us to conceive how a thing indifferent in itself may become a source of pleasure by being connected in the mind with something else which is naturally agreeable; but it presupposes in every instance the existence of those notions and those feelings which it is its province to combine: insomuch that it will be found wherever association produces a change in our judgments in matters of taste, it does so by coöperating with some natural principle of the mind, and implies the existence of certain original sources of pleasure and uneasiness. This suggests a distinction in the circumstances which please in the objects of taste, between those which please in consequence of casual associations and those which are fitted to please by nature. The perfection of taste in reference to the last depends upon the degree in which the mind is free from casual associations; in reference to the first it depends upon the facility with which such associations are formed. (*Elements of the Philosophy of the Human Mind*, c. v., p. ii., p. 364, 4to.)

The different modes in which association operates have been illustrated with much elegance, and their true place in the philosophy of taste distinguished, by Mr. Alison: ' Fashion,' he remarks, ' may be considered in general as the custom of the great. It is the dress, the furniture, the language, the manners of the great world, which constitute what is called the fashion in each of these articles, and which the rest of mankind are in such haste to adopt after their example. Whatever the real beauty or propriety of these articles may be, it is not in this light that we consider them. They are the signs of that elegance and taste and splendour which is so liberally attributed to elevated rank: they are associated with the consequence which such situations bestow; and they establish a kind of distinction between this envied station and those humble and mortifying conditions of life to which no man is willing to belong. It is in the light therefore of this connection only that we are disposed to consider them; and they accordingly affect us with the same emotion of delight which we receive from the consideration of taste or elegance in more permanent instances.' (*Essays on Taste*, Essay i.)

Association then can only modify, it cannot wholly account for our emotion of taste, and it cannot even modify except by operating in a manner which implies certain original sources of pleasure and uneasiness in the objects of our emotion. In some cases association heightens the agreeable or disagreeable effect of objects; in others all the delight or disgust which we experience can be resolved into the influence of association. The distinction implies the fact insisted on. What constitutes the distinction, or where are we to find its explanation? We may with propriety employ our reason in reducing particular phenomena to general principles; but we must in the end arrive at principles of which there is no other account to be given than that such is the will of the author of our nature. We cannot explain why such forms please or displease; we must stop short at the discovery of the respects in which they please or displease. (Stewart.)

Sir Joshua Reynolds has referred the idea of beauty to some ' central form ' in the objects of our perception. ' All the objects which are exhibited to our view by nature, upon close examination, will be found,' he says, ' to have their blemishes and defects. The most beautiful forms have something about them like weakness, minuteness, or imperfection: but it is not every eye that perceives these blemishes; it must be an eye long used to the contemplation and comparison of these forms; and which, by a long habit of observing what any set of objects of the same kind have in common, has acquired the power of discerning what each wants in particular. This long laborious comparison should be the first study of the painter who aims at the greatest style. By this means he acquires a just idea of beautiful forms; he corrects nature by herself, her imperfect state by her more perfect. His eye being enabled to distinguish the accidental deficiencies, excrescences, and deformities of things from their general figures, he makes out an abstract idea of their forms more perfect than any one original; and, what may seem a paradox, he learns to design naturally by drawing his figures unlike to any one object. (*Discourse III.*) He observes in explanation in another part of the same discourse: ' To the principle I have laid down, that the idea of beauty in each species of beings is an invariable one, it may be objected, that in every particular species there are various central forms which are separate and distinct from each other, and yet are undeniably beautiful; that in the human figure, for instance, the beauty of Hercules is one; of the Gladiator another; of Apollo another; which makes so many different ideas of beauty. It is true indeed that these figures are each perfect in their kind, though of different characters and proportions; but still none of them is the representation of an individual, but of a class: and as there is one general form which, as I have said, belongs to the human kind at large, so in each of these classes there is one common idea and central form, which is the abstract of the various individual forms belonging to that class. Thus, though the forms of childhood and age differ exceedingly, there is a common form in childhood and a common form in age, which is the more perfect as it is more remote from all peculiarities. But . . . . though the most perfect forms of each of the general divisions of the human figure are ideal, and superior to any individual form of that class, yet the highest perfection of the human figure is not to be found in any one of them. It is not in the Hercules, nor in the Gladiator, nor in the Apollo, but in that form which is taken from all, and which partakes equally of the activity of the Gladiator, of the delicacy of the Apollo, and of the muscular strength of the Hercules. For perfect beauty in any species must combine all the characters which are beautiful in that species. It cannot consist in any one to the exclusion of the rest; no one therefore must be predominant, that no one may be deficient. . . . There is likewise a kind of symmetry or proportion which may properly be said to belong to deformity. A figure lean or corpulent, tall or short, though deviating from beauty, may still have a certain union of the various parts, which may contribute to make them on the whole not unpleasing.'

This theory (the principle of which extends to other objects of taste besides those contemplated by Sir Joshua Reynolds) reconciles the apparent inconsistency, insisted on by Mr. Payne Knight and by other writers of the same school, between the decisions of taste in one country and in another, as tending to show that the standard of taste is wholly arbitrary. The ideal beauty of the African is the result of the process which has been described applied to the coloured inhabitants of Africa, as the ideal beauty of the European is the result of the same process applied to the inhabitants of Europe. To institute a comparison between the beauty of the European and that of the African, and to conclude that taste has no invariable

principles as its foundation, from the opposite decisions on such a comparison, involves the same description of error as it would be to arrive at the same conclusion from the opposite decisions in a comparison between the beauty of two distinct species of animals, the one biped and the other quadruped. There is a 'central form' of beauty proper to the different races of mankind; to the two sexes of the different races; to different ages; and so on in reference to inferior animals and objects of inanimate nature. We trespass beyond the province of mere taste when we compare objects in respect to which the principles of beauty are altogether distinct.

Much obscurity has arisen in discussions on the subject of taste from the twofold sense in which the word taste has been employed, as expressive of an emotion, and of something objective in which there exists an aptitude to produce emotion. The term taste strictly applies to the emotion only; the theory of the different causes by which the emotion is produced belongs to the subject of beauty. We have been obliged to refer to the theory of beauty in the preceding part of this article in establishing the reality of certain principles determining our emotions of taste: in what follows we shall confine ourselves to the explanation of taste in its restricted or proper sense.

When any object either of sublimity or beauty is presented to the mind, we are conscious of a train of thought being immediately awakened analogous to the character or expression of the original object. The landscapes of Claude, the music of Handel, the poetry of Milton, excite feeble emotions in our minds when our attention is confined to the qualities they present to our senses, or when it is to such qualities of their composition that we turn our regard. It is then only we feel the sublimity or beauty of their productions, when our imaginations are kindled by their power, when we lose ourselves amid the number of images that pass before our minds, or when we waken at last from the play of fancy as from the charm of a romantic dream. (Alison, c. i., sect. 1.)

The trains of thought which are thus suggested are distinguished in the nature of the ideas or conceptions which compose them, and in the nature or law of their succession. In the case of those trains of thought which are suggested by objects either of sublimity or beauty, they are in all cases composed of ideas capable of exciting some affection or emotion. Mr. Alison has supposed that not only the whole succession is accompanied with that peculiar emotion which we call the emotion of beauty or sublimity, but that every individual idea of such a succession is in itself productive of some simple emotion or other. But to this it has been objected, and we think truly, that such a train of images passing before the mind, and images accompanied with lively emotion, could scarcely fail to be remembered by us; or, at least, if they are not remembered by us, there is no reason, *à priori*, to suppose the existence of them. (Brown, *Lectures on the Philosophy of the Human Mind*, lecture lvii.)

There is this distinction between the emotions of taste and all our different emotions of simple pleasure, that in the case of these last emotions no additional train of thought is necessary. The pleasurable feeling follows immediately the presence of the object or quality, and has no dependence upon anything for its perfection but the sound state of the sense by which it is received. The emotions of envy, pity, benevolence, gratitude, utility, propriety, novelty, &c. might undoubtedly be felt, although we had no such power of mind as that by which we follow out a train of ideas, and certainly are felt in a thousand cases when this faculty is unemployed. In the case of the emotion of taste, on the other hand, it seems evident that this process of mind is necessary, and that unless it is produced these emotions are unfelt. Whatever may be the nature of that simple emotion which any object is fitted to excite, whether that of gaiety, tranquillity, melancholy, &c., if it produce not a train of kindred thought in our minds, we are conscious only of that simple emotion. Whenever, on the contrary, the train of thought which has been mentioned is produced, we are conscious of a higher and more pleasing emotion; and which, though it is impossible to describe in language, we yet distinguish by the name of the emotion of taste. The emotions of taste may therefore be considered as distinguished from the emotions of simple pleasure, by their being dependent upon the exercise of our imagination; and though founded in all cases upon simple emotion, as yet further requiring the employment of this faculty for their existence (*Essay* i., conclusion, s. ii., Alison); or, rather than the *employment* (a word which seems to intimate a deliberate intended act, in the process of imagination), as Dr. Brown would say, the operation of the common laws of suggestion in the mode to which we apply the word imagination.

The suggestion of trains of kindred or harmonising images which has been pointed out as distinguishing the emotion of taste, accounts for the more enlarged susceptibility in some than in others of this emotion. The more our ideas are increased or our conceptions extended upon any subject, the greater the number of associations we connect with it, the stronger is the emotion of sublimity or beauty we receive from it. 'What is it' (says Mr. Alison) 'that constitutes that emotion of sublime delight, which every man of common sensibility feels upon the first prospect of Rome? It is not the scene of destruction which is before him. It is not the Tiber, diminished in his imagination to a paltry stream, and stagnating amid the ruins of that magnificence which it once adorned. It is not the triumph of superstition over the wreck of human greatness, and its monuments erected upon the very spot where the first honours of humanity have been gained. It is antient Rome which fills his imagination. It is the country of Cæsar, and Cicero, and Virgil, which is before him. It is the mistress of the world which he sees, and who seems to him to rise again from her tomb, to give laws to the universe. All that the labours of his youth or the studies of his maturer age have acquired, with regard to the history of this great people, open at once before his imagination, and present him with a field of high and solemn imagery, which can never be exhausted.'

'The beauty of a theory or of a relic of antiquity is unintelligible to a peasant. The charms of the country are altogether lost upon a citizen who has passed his life in town.' It is on the principle in question that Burke remarks that the excellence and force of a composition must always be imperfectly estimated from its effect on the minds of any, except we know the temper and character of those minds. (*Introduction to the Sublime and Beautiful.*)

The rules by which taste is determined vary with the objects to which its decisions refer; but in respect to all, this general principle holds, that a composition is to be judged by its fitness to produce the end designed by it. If to please, to instruct, to move, to create laughter, be its design, its merits are to be determined by its aptitude to produce any of these effects. If its objects be to please, &c. only a particular people or class, it is to be estimated under the given circumstances. If its object be to give pleasure or instruction to all ages and conditions of society, it is to be estimated by its correspondence with those universal principles of human nature which it contemplates. That composition is the highest which is of the last description. (Hume's *Essay on the Standard of Taste.*)

The reader who may desire to see this subject further discussed is referred to the article Beauty; to Mr. Alison's *Essays;* to Brown's *Lectures on the Philosophy of the Human Mind*, lecture lvii.; Hume's *Essay on the Standard of Taste.*

TATARS. [Tartars.]

TATE, NAHUM, was born in Dublin in the year 1652. His father was Dr. Faithful Tate, a clergyman in Ireland. He was educated at Trinity College, Dublin, whence he removed to London. On the death of Shadwell in 1690, the interest of Tate's friends procured him the situation of poet-laureate, which he held till his death. He seems to have been an improvident man, and somewhat addicted to intemperance. In the latter part of his life he resided in the precincts of the Mint, in Southwark, where he died, August 12, 1715. The Mint was then considered a privileged place, where debtors were not liable to arrest. This supposed privilege however was put down by statute 9 Geo. I.

Tate wrote 'Memorials for the Learned, collected out of eminent Authors in History,' 8vo., 1686; 'Characters of Virtue and Vice described and attempted in Verse, from a Treatise of Joseph Hall, Bishop of Exon,' Lond., 1691; 'Miscellanea Sacra, or Poems on Divine and Moral Subjects,' Lond., 1698, 8vo.; 'Panacea, a Poem on Tea,

Lond., 1700; besides Birth-Day Odes, and an Elegy on the death of Queen Mary. He was also the author of about ten dramatic pieces, tragedy, comedy, and opera, including an alteration of Shakspere's 'Lear,' which kept the stage many years, but has for some time been superseded by the original.

Tate is chiefly known now by his metrical version of the Psalms, which he executed in conjunction with Dr. Nicholas Brady [BRADY], and which is now commonly annexed to the Book of Common Prayer of the Church of England. This version, though not of high merit, has deservedly taken the place of the former version by Sternhold and Hopkins. [STERNHOLD.] The first publication was an 'Essay of a New Version of the Psalms of David, consisting of the first Twenty, by N. Brady and N. Tate,' Lond., 1695, 8vo.; this was followed by 'A New Version of the Psalms of David, fitted to the Tunes used in the Churches, by N. Tate and N. Brady,' Lond., 1698, with a 'Supplement of Church Hymns,' Lond., 1700, 8vo.

(Baker's *Biographia Dramatica*, by Reed and Jones; Watt's *Bibliotheca Britannica*.)

TATIA'NUS, of Assyria, was a pupil of Justin Martyr, after whose death he wrote an apology for Christianity, under the title of 'A Discourse to the Heathen' (Λόγος πρὸς Ἕλληνας). In this work he gives some account of his own life. He was brought up in heathenism, the different forms of which became known to him by his many travels; and all those forms appeared to him unsatisfactory. He then turned his attention to the Old Testament, on which he thought he saw the impress of truth. Arriving at Rome, where he practised as a rhetorician, he met with Justin Martyr, by whom he was converted to Christianity.

After the death of Justin he embraced some heretical opinions, the germs of which may be seen in his 'Discourse to the Heathen.' The chief of his heresies were the Marcionite doctrines of the two principles of good and evil, and of the evil of matter [MARCIONITES], and the Valentinian doctrine concerning Aeons. His followers were however chiefly remarkable for the practical application they made of their Marcionite opinions by lives of the strictest asceticism. They lived in celibacy, refused all luxuries, and abstained from the use of wine even at the Lord's Supper. Hence they were called Encratites (ἐγκρατῖται), Apotactites (ἀποτάκτικοι), and Hydroparastatae (ὑδροπαραστάται). But it must be observed that these terms were often applied to all ascetics. The Tatianists were Encratites, but all called Encratites were not Tatianists. The date of Tatian's heresy is placed by Eusebius in the year A.D. 172.

Of his lost works the chief were a treatise on 'Perfection after the Pattern of the Saviour' (περὶ τοῦ κατὰ τὸν σωτῆρα καταρτισμοῦ), and a 'Harmony of the Four Gospels' (εὐαγγέλιον διὰ τεσσάρων). The latter work is particularly noticed by Theodoret, who found 200 copies of it in the Syrian churches, which he took away from the people on account of the heresies contained in the book. For this reason, chiefly, Neander supposes that the Harmony of Tatian was not simply compiled from the narratives of the four Evangelists, but contained also many things out of the Apocryphal Gospels. Some writers, among whom is Lardner, think that Tatian's 'Harmony' is still extant in an Arabic MS. in the Vatican Library.

His 'Apology' is usually printed with the works of Justin Martyr. There are separate editions of it by Gesner, Zürich, 1546, fol.; and by Worth, Oxon., 1700, 8vo.

(Eusebius, *Hist. Ecc.*, iv. 29; Hieronymus, *De Vir. Illust.*, c. 29; Clemens Alexand., *Strom.*, iii. 12; Lardner's *Credibility*, pt. ii., c. xiii., &c.; xxxvi., sec. 2; Neander's *Gesch. der Christ. Relig. und Kirche*, i., p. 762, and p. 1131.)

TATIUS, ACHILLES. [ACHILLES TATIUS.]

TATTA. [HINDUSTAN, xii., 221.]

TATTERSHALL. [LINCOLNSHIRE.]

TATTOOING is the name usually given to the custom, common among many uncivilized tribes, of marking the skin by punctures or incisions, and introducing into them coloured fluids, so as to produce an indelible stain. It is mentioned in Captain Cook's account of the South Sea islanders under the name *tattowing;* and, with trifling difference in the orthography, the same name is applied by English writers to similar practices among other people. The word 'tattoo' appears to be formed by a reduplication of a Polynesian verb 'ta,' meaning to strike, and therefore to allude to the method of performing the operation, and, if this supposition be correct, it has a curious resemblance to the English word tattoo, meaning a particular beat of the drum.

From a passage in the book of *Leviticus*, chap. xix., v. 28, in which the Israelites are forbidden to make any cuttings in their flesh for the dead, or to *print any marks* upon their bodies, it has been supposed that some custom resembling tattooing was practised in the time of Moses. A note upon this passage in the 'Pictorial Bible' states, that although tattooing seems to have been commonly regarded in England rather as a custom of savage islanders than anything more, it is also an Oriental custom, and that too among people whose proximity to the Hebrews affords a reason for the prohibition contained in the text referred to. 'The Bedouin Arabs, and those inhabitants of towns who are in any way allied to them,' observes the author of this note, 'are scarcely less fond of such decorations than any islanders of the Pacific Ocean. This is particularly the case among the females, who, in general, have their legs and arms, their front from the neck to the waist, and even their chins, lips, and other prominent parts of the face marked with blue stains in the form of flowers, circles, bands, stars, and various fanciful figures. They have no figures of living objects, such being forbidden by their religion; neither do they associate any superstitions with them, so far as we are able to ascertain. They probably did both before the Mohammedan æra, as their descendants in the island of Malta do at present. The men there generally go about without their jackets, and with their sleeves tucked up above their elbows, and we scarcely recollect ever to have seen an arm, thus bare, which was not covered with religious emblems and figures of the Virgin, or of some saint under whose immediate protection the person thus marked conceived himself to be.' 'Thus also,' proceeds the author, 'persons who visit the holy sepulchre and other sacred places in Palestine have commonly a mark impressed on the arm in testimony of their meritorious pilgrimage.' The works of antient writers contain many notices of the practice of tattooing, as practised by several barbarous races. As to the Britons, Cæsar merely describes their custom of staining their bodies with vitrum, or woad; but 'Solinus represents the process as a laborious and painful one, but permanent in its effect; and speaks of the painting as consisting chiefly of the figures of animals, that grew with the growth of the body. Herodian says they punctured their bodies with the figures of all sorts of animals. Isidore is still more explicit; for, in speaking of the Picts, whose name he derives from their coloured skins, he tells us that the painting was done by squeezing out the juice of certain herbs upon the body, and puncturing the figures with a needle.' (*Pictorial History of England*, vol. i., p. 129.) Cæsar supposed that this practice was adopted for the purpose of terrifying their enemies; but probably this kind of skin-painting was the national dress, and if so, it may have existed in its highest state of perfection at a period anterior to the Roman invasion. Tattooing may also have been practised by our ancestors as a means of distinction, as well as from the love of ornament. Thus Herodotus, who describes the habits of the Thracians, says that to be tattooed or marked (ἐστίχθαι) was an emblem of rank, and the want of it indicated meanness of descent (v. 6). The extended use of clothing at a later period rendered such ornaments superfluous, and led to the decline and subsequent abandonment of the practice. 'It is therefore,' says the 'Pictorial History of England,' 'that we hear no more of this tattooing in the south (of Britain) after it was subdued and civilised into a Roman province, though it still continued among the rude tribes of the north, where it lingered until it was banished thence also by the full attire of civilization.' In a subsequent part of the same volume (p. 329) it is stated that the custom of tattooing, or puncturing the skin, was practised by the Anglo-Saxons as well as by the Britons, and that a law was passed against it in the year 785. It was nevertheless continued during the whole of the Anglo-Saxon period, and is among the English vices reprobated by William of Malmesbury after the Norman conquest. Several other antient notices on the subject are collected by Lafitau, in his 'Mœurs des Sauvages Amériquaines,' which work is cited in the volume on the 'New Zealanders' in the 'Library of Entertaining Knowledge,' where much information respecting tattooing is given.

In modern times the custom of tattooing has been found in most of the islands of the Pacific Ocean, and among many of the aboriginal tribes of Africa and America, as well as, on a limited scale, as before stated, in the East. Much curious information on the various kinds of tattooing is collected in the volume on the 'New Zealanders,' previously cited. From this work we condense the following account of the process of tattooing, as performed in New Zealand upon an English sailor, named John Rutherford, who was captured by the natives in 1816, and resided among them for nearly ten years, and upon some companions who were taken with him:—The natives having seated themselves on the ground in a ring, the Englishmen were placed in the middle, stripped of their clothes, laid down on their backs, and held by five or six men each, while two others commenced the operation of tattooing. Having taken a piece of charcoal, and rubbed it upon a stone with a little water, so as to produce a thick liquid, they dipped into it an instrument made of bone, with a sharp edge like a chisel, and shaped in the fashion of a garden-hoe. They then applied the instrument to the skin, and struck it twice or thrice with a piece of wood, thereby making it cut into the flesh as a knife would have done, and causing a great deal of blood to flow, which they kept wiping off with the side of the hand, in order to see whether the impression was made sufficiently clear. If not, they applied the cutting-instrument again to the same place. Various instruments were however employed in the course of the operation, one sort being made of a shark's tooth, and another having a serrated edge; and they were used of different sizes, to suit the different parts of the work. Rutherford states that the pain was most acute, and that, although the operators were very quick and dexterous, he was four hours under their hands; and he was completely blinded for a time by the operation. In three days the swelling occasioned by it had greatly subsided, and he began to recover his sight; but six weeks elapsed before he was completely well. Rutherford's account agrees with those of other observers, excepting in the circumstance of the whole operation being performed at once, while both Captain Cruise and Mr. Marsden state that it required several months, and sometimes several years, to complete the tattooing of a chief, owing to the necessity of allowing one part of the face or body to heal before commencing the decoration of another part; but, besides the probability that this might apply only to the more intricate patterns, or to cases in which the tattooing extended over a larger portion of the person than in the case of Rutherford, it is possible that the natives may have designed to put his powers of endurance to a severer test than would be required of a native. Captain Cruise states that the New Zealanders occasionally renew their tattooing, as the lines grow faint by lapse of time; and from various accounts it would appear that the tincture introduced into the wound (on the edge of the cutting-instrument) is sometimes obtained from the juice of a tree; and that, before the cutting is commenced, the intended figure is traced upon the skin with a burnt stick, or a piece of red earth. The age for performing the operation appears to vary from eight or ten years up to about twenty; and the females are not required to submit to anything beyond a slight tattooing of the face. Those among whom Rutherford lived had the inside of their lips tattooed,* as well as having marks on the chin, forehead, and sides of the nose and mouth; while the men were commonly tattooed on the face, hips, and body, and some as low as the knee. The most complicated patterns are found upon chiefs of the highest order; and their peculiar devices, or, as they are called, *amocos*, form distinctions which, in some cases, take the place of the sign-manual of the individuals to whom they belong. An instance is related in the 'Missionary Register' for 1816, in which a chief in the Bay of Islands, on making a grant or conveyance of a piece of land to some missionaries, had a drawing of the tattooing of his face affixed in lieu of a signature; while an attesting witness added, in like manner, a copy of the pattern on one of his cheeks. Of the character of these patterns a better idea will be conveyed by the annexed bust of Shungie, copied from an engraving in the 'Missionary Register' for 1816, than by the most lengthened description. After it is inserted a copy of a drawing, executed by Tupai Cupa, a New Zealand chief, without the aid of a glass, of his own amoco, or tattooed pattern. This interesting individual also drew from memory, while in England, the amocos of his brother and of his eldest son; and such was the force of association in his mind, that, on finishing the latter, he held it up, gazed at it with a murmur of affectionate delight, kissed it repeatedly, and finally burst into tears.

Head of Shungie, from a carving by himself.

Tattooing on the face of Tupai Cupa, from a drawing by himself.

The process of tattooing as practised, or rather as it was formerly practised, in other islands of the South Sea, was less painful than that followed in New Zealand; for, according to the account of Captain Cook, in some cases the punctures could hardly be said to draw blood. The instruments used were edged with small teeth, somewhat resembling those of a fine comb; and, as in the case of New Zealand, the colouring tincture was introduced at the same operation as that by which the skin was punctured; the substance employed in some places being a kind of lamp-black. On the brown skins of the natives, the marks made with this substance appear black; but on the skin of a European they are of a fine blue colour.* Lafitau speaks of powdered charcoal as the colouring-matter commonly used by the American Indians; and states that it was introduced by a process subsequent to that of cutting or puncturing the skin. This insertion of the colour appears to have been the most painful part of the operation of tattooing as practised among them.

* According to the narrative of the voyage of H.M.S. Blonde to the Sandwich Islands, the ladies of Hawaii (the Owhyhee of Captain Cook) follow the singular practice of tattooing the tips of their tongues, in memory of their departed friends.

* Rutherford states that the tattooing on the inside of the lips of New Zealand women appears of a blue colour.

In addition to the other reasons which have been alluded to for the general adoption of the practice of tattooing among savage tribes, it is likely that it may be regarded as an important part of the initiation of a warrior, of whose passive courage it is a severe test. 'Thus,' observes the author of the 'New Zealanders,' 'in the account which Rochefort, in his 'History of the Antilles' (p. 108), gives of the initiation of a warrior among the people of those islands, it is stated that the father of the young man, after a very rude flagellation of his son, used to proceed to scarify (as he expresses it) his whole body with the tooth of the animal called the *acouti*; and then, in order to heal the gashes thus made, he rubbed into them an infusion of pimento, which occasioned an agonizing pain to the poor patient; but it was indispensable that he should endure the whole, adds our author, without the least contortion of countenance or other evidence of suffering.'

(*Pictorial Bible*, note on Levit. xix., 28; *Pictorial History of England*, vol. i., pp. 129 and 329; *New Zealanders*, 'Lib. of Ent. Knowledge,' chapters vi. and xiv.)

TAUBMANN, FRIEDRICH, was born at Wonsces, near Baireuth, on the 16th of May, 1565, where his father was a shoemaker. His father died very early; and his mother married a tailor, who wished to bring up his stepson Friedrich to his own business; but as the boy showed little inclination, he was sent, in 1577, to school at Culmbach, where he was obliged to gain his livelihood by singing and begging. In 1582 he went to the gymnasium of Heilbronn, where his Latin verses and the wit displayed in them were so much admired, that he was crowned by Paul Melissus as poet-laureate. Ten years later he went to the University of Wittenberg, where he distinguished himself, and, in 1595, was appointed professor of poetry and eloquence, to which afterwards the honour of court-poet was added. He died at Wittenberg, on the 24th of March, 1613.

Taubmann was conscientious in the discharge of his official duties, and he was a witty and humorous man. During his lifetime he had the reputation of being the greatest wit of the age, and persons of the highest rank sought his society. From all that can be learned about him, it is clear that he did not, like many others in similar positions, forget his own dignity as a man: he never acted as a buffoon or flatterer, but always manifested a straightforward and upright character. In his time philology was sinking very rapidly in Saxony, all attention being absorbed by theological controversies and sophistries, and Taubmann was one of the very few who, both in earnest and in jest, impressed upon his contemporaries the necessity of resuming a thorough study of the antient languages as the only means of raising theological studies to their proper position. This he did more especially in his work, 'Dissertatio de Lingua Latina,' the last edition of which appeared at Wittenberg, 1614. With the same view he exerted himself in his lectures, and in his editions of Plautus (Wittenberg, 1621, 4to.) and of Virgil (Wittenberg, 1618, 4to.), in which he made his countrymen acquainted with the labours of foreign scholars. His poetical works, though very popular in his time, have no great merit. They appeared in several collections, under the titles of 'Columbae Poeticae,' 'Melodaesia,' 'Schediasmata Poetica,' and others. After Taubmann's death, the name of Taubmanniana was applied to all kinds of witty sayings and anecdotes.

(Erasmi Schmidii *Oratio in Taubmanni Memoriam*, Wittenberg, 1613, 8vo.; *Taubmanniana, oder Fr. Taubmann's Leben, Anecdoten, witzige Einfälle und Sittensprüche*, von Simon von Cyrene, Leipzig, 1797, 8vo.; Fr. Brandt, *Leben und Tod Frid. Taubmanni*, Copenhagen, 1675, 8vo.: the best work however is by Ebert, *Leben und Verdienste Fr. Taubmanns*, Eisenberg, 1814, 8vo.)

TAULER, or THAULER, JOHANN, the most celebrated German divine of the fourteenth century. He was born in 1294, as some writers say, at Cologne, but according to others at Strassburg. Respecting his life very little is known. He entered the order of the Dominicans at an early age, and was held in the highest esteem on account of his knowledge of philosophy and mystic theology, as well as for his pious and unblemished conduct, although he fearlessly attacked the vices and follies of his fellow-monks. The latter part of his life he spent in the convent of the Dominicans at Strassburg, where he died on the 16th of June, 1361, as is attested by his tomb-stone, which still exists in that city.

Tauler was a man of extraordinary piety and devotion, a zealous teacher, and a great promoter of mystic theology in Germany, which must regard him not only as the founder of that school of divinity, but at the same time as one of the greatest men that have ever sprung from it. His sermons, as well as his other religious and ascetic works, show a glowing imagination and deep feeling: they are less addressed to the understanding than to the heart. But although this leaning and his love of the mysterious frequently led him to religious sentimentality and absurdities, yet he never sinks down to the level of some modern mystic divines. Tauler was deeply read in scholastic philosophy, and although in his sermons he endeavours to steer clear of it, yet they are not quite free from sophistic subtleties, and there are passages which must have puzzled more than enlightened his audience. In his love of truth, and the earnestness with which he devoted himself to the instruction of the people, he was a worthy predecessor of Luther. Tauler's influence upon the German language and literature has acquired for him as distinguished a place in the history of German literature as that which he occupies among divines. In his time German prose scarcely existed, and the standard of sermon-writing was very low. The creation of a prose literature belongs almost exclusively to him: his style seldom aims at oratorical beauty, his sentences are short and abrupt, but always full of meaning. His language, which is the dialect of the Upper Rhine, is as pure as can be expected. It appears that Tauler did not himself write his sermons, but they were taken down as they were preached, by many of his hearers. We must therefore suppose that in the editions which were published shortly after his death, the form has been somewhat altered by the editors. The first edition of his sermons appeared at Leipzig, 1498, in 4to., under the following title: 'Sermon des grossgelarten in gnaden erleuchteten Doctoris Johannis Tauleri predigerr ordens, weisende auff den nehesten waren wegk, yn geiste czu wandern durch uberschwebenden syn, unvoracht von geistes ynnige vorwandelt ī deutsch manchen menschen zu selikeit.' This edition was followed by another at Augsburg, 1508, fol., and a more complete one at Basel, 1521, fol. A translation of these sermons into the dialect of Lower Germany was published at Halberstadt, in 1523, fol., and another into High German by P. J. Spener, at Nürnberg, 1688, 4to. A new edition in modern High German was published at Frankfurt-on-the-Main, in 3 vols. 8vo., 1825, &c. The most interesting among his other religious works is that on the imitation of the life of Christ, 'Nachfolgung des armen Lebens Christi,' which was first printed at Frankfurt in 1621. The most recent edition is that by Schlosser, Frankf., 1833. A collection of all the treatises of Tauler was commenced in 1823, at Luzern, by N. Cas. seder, but only two volumes have appeared.

Most of the works of Tauler were translated into Latin by Laurentius Surius, Cologne, 1548, fol.: this collection has been reprinted at Macerata and Paris. There are also one Italian and three Dutch translations: the best of the Dutch translations is that of Antwerp, 1685, fol.

A list of the works of Tauler, together with the whole literature on the subject, is given in Jörden's *Lexicon Deutscher Dichter und Prosaisten*, vol. v., p. 1-9.

TAUNTON, an antient town in the south-western part of Somersetshire, situated in a fertile vale called Taunton Dean, and distant 141 miles from London, 44 from Bristol, and 33 from Exeter. Roman coins and other antiquities have been found, from which it has been inferred that there was a Roman station here. Taunton was certainly a place of considerable importance in the Anglo-Saxon period; and in the eighth century a castle was built here by Ina, king of the West Saxons, in which he held his first great council. The building was destroyed by his queen in expelling one of the kings of the South Saxons. An other castle was built after the Conquest by one of the bishops of Winchester, to whom the town and manor were granted; and the present remains are believed to be those of a still more recent edifice. Perkin Warbeck held possession of the castle and town for a short time; and in the civil wars the town sustained a long siege under Colonel (afterwards Admiral) Blake, against 10,000 royalist troops, until relieved by Fairfax.

The town is about a mile long; the principal streets are

well paved, and lighted with gas; and the houses of brick, of respectable appearance. Apart from the main thoroughfares are some very poor streets, which, before the enlargement of the borough, were inhabited by persons desirous of profiting by the parliamentary franchise. The woollen manufacture was established at Taunton in the fourteenth century, but has long since decayed; and at present the silk manufacture is carried on, though not to any great extent. The river Tone flows on the north-western side of the town, and is crossed by a stone bridge of two arches; but the river is only partially navigable, and in 1811 a canal was projected between Taunton and Bridgewater, a distance of 12¼ miles. This canal is of great importance to the prosperity of the town and district, by enabling it to export agricultural and other produce to Bristol and other places, from which it receives groceries, coal, and other commodities in return: there is a branch from this canal to Chard. In July, 1842, the railway from Bristol to Exeter was opened as far as Taunton, so that there is now a railway communication with the metropolis. The markets, held twice a week, are very abundantly supplied with fish, fruit, and every kind of provisions. The market-house stands in a spacious open area called the Parade, and is a brick building of considerable size; the upper part comprises the guildhall and an assembly-room, and the lower part consists of an arcade on each side, in one of which the corn-market is held. On market-days the Parade, which is enclosed by iron posts and chains, is occupied by butchers' stalls. On the west side of the Parade there is a handsome building of the Ionic order, erected in 1821, the upper part of which is appropriated as a library, museum, and reading-room; and underneath, and in the rear, are the markets for fish, poultry, dairy produce, &c. The Taunton and Somerset Institution, established in 1823, contains a good though not extensive library, and a large public reading and news room. The theatre is a small neat building. Two weekly newspapers are published at Taunton. There are three churches. The church of St. Mary Magdalen is a spacious and very handsome edifice in the florid Gothic style. The quadrangular tower at the west end, 153 feet high, is much enriched, and is a work of great beauty. The value of the living, which is a vicarage, is not given in the Reports of the Ecclesiastical Commissioners. St. James's church is a plain edifice, with an antient square tower formerly belonging to the conventual church of the priory. The living is a perpetual curacy, of the annual value of 255*l*. Trinity church was consecrated 18th June, 1842. It is in the Gothic style, built of white lias stone, with dressings of Bath stone, and contains sittings for above one thousand persons. It stands on elevated ground, about half a mile from the parish church, in a poor and populous part of the town. There are two chapels belonging to the Wesleyan Methodists, one erected in 1778 under the direction of Wesley. The Roman Catholics, Independents, Baptists, Quakers, and Unitarians have chapels. The free grammar-school was founded by Fox, bishop of Winchester, in 1522. The premises are situated within the castle-gate, and consist of a large and antient school-room, and under the same roof is the dwelling-house of the master. The endowment is worth about 36*l*. a year. The number of infant, Sunday, and daily schools at Taunton was stated in 1833 to be very inadequate, and a large number of poor children were at that time receiving no education. There are various almshouses and other charities, all of which are noticed in the Report of the Charity Commissioners (vol. v., p. 484-542). The Taunton and Somerset hospital was opened in 1812; and there are other medical charities.

Charles I. granted the burgesses a charter of incorporation. In the reign of Charles II. they were deprived of this charter, in consequence of the town having displayed so much zeal for the parliament, but it was restored, and in 1792 became forfeited by the corporate body having neglected to fill up vacancies. The town then came under the jurisdiction of the county magistrates, and is still without a municipal government. The bailiffs and constables, as the principal officers of the town, take a prominent part in all public proceedings. Taunton has returned members to parliament since 1295 (23 Henry I.). Before the Reform Act the right of election was in the potwallers who had been six months resident and were not in the receipt of charitable relief. The town having outgrown the antient limits of the borough, which was wholly within the parish of St. Mary Magdalen, a new boundary was adopted, so as to comprise parts of the following parishes:—St. Mary Magdalen on the east, St. James's on the north, Bishop's Hull on the west, and Wilton on the south. By this extension the population of the borough was increased from 5580 to 12,148, according to the census of 1831. In 1826 the number of electors polled was 739; in 1840 the number on the register amounted to 1010, including 216 of the old potwallers. Two members are returned to parliament. The Lent assizes and the Michaelmas quarter-sessions are held at Taunton. There is a court for debts under forty shillings, the jurisdiction of which extends over the hundred. There is no prison, except a lock-up or place of temporary confinement. The county courts and offices are within an irregular quadrangle consisting of the remains of the castle.

(Toulmin's *Hist. of Taunton*, 1791; a new edition by Savage, 1822.)

TAUNUS. [GERMANY.]

TAURELLIUS, L. [TORELLI.]

TAURICA CHERSONE'SUS was the antient name of the peninsula which juts out southwards from European Sarmatia, between the Pontus Euxinus (Black Sea) and the Palus Maeotis (Sea of Azof): it is now called the Crimea. It is called Chersonesus Trachea by Herodotus, who compares it to the promontory of Sunium (iv. 99). Its form, size, and physical features are described under CRIMEA. The isthmus which connects it with the mainland was called Taphros or Taphrae (*Τάφρος, Τάφραι*), and there appears to have been a town of the same name upon the isthmus.* (Strabo, vii., p. 308; Pliny, iv. 26; Mela, ii. 1.) On the west of this isthmus was the Sinus Carcinites (*Κόλπος ὁ Καρκινίτης*), now the Gulf of Perekop; and on the east the shallow waters then, as now, called the Putrid Sea or Lake (*ἡ Σαπρὰ Λίμνη*, Palus Putris). The south-western point of the peninsula was the promontory Parthenion (*τὸ Παρθένιον*), which is either the modern Cape Chersonese, or another promontory farther south, in the neighbourhood of the town of Sviatoi Gheorghi. The southern promontory was called Criu-Metopon (*Κριοῦ μέτωπον*), and either the south-eastern or the eastern point of the island was called Corax (*τὸ Κόραξ ἄκρον*). On the east the peninsula is divided from the coast of Asia by the Cimmerian Bosporus (*ὁ Κιμμέριος Βόσπορος*), now the Strait of Kertch or Yenikale. On the south-western side of the peninsula is a small peninsula terminated by Cape Khersonese, and enclosed on the north by the Gulf of Achtiar, the antient Portus Ktenus (*Κτενοῦς*), and on the south by the Gulf of Balaklava, the antient Portus Symbolorum (*Συμβόλων λιμήν*). On this peninsula, at the distance of 100 stadia from the promontory Parthenion (Strabo), stood the city of Chersonesus (*Χερρόνησος*) or Cherrone (Mela), the full name of which was Chersonesus Heracleotica. It was a colony of Heraclea in Pontus. The peninsula itself was called the Small Chersonesus, and the Chersonesus Taurica was sometimes called the Great Chersonesus, to distinguish it from this part of itself. The other important towns were, on the isthmus, Taphros (*ἡ Τάφρος*), now Perekop; on the west coast Eupatoria (*Εὐπατορία*), now Eupatoria or Kazlov, built by Mithridates Eupator; on the east coast Theodosia (*ἡ Θεοδοσία*, or *ἡ Θευδοσία*), now Kefa or Feodosia, a colony of the Milesians; at the eastern end of the island, on the Bosporus, Pantienpaeum or Bosporus (*Παντικάπαιον*), now Kertch. There were several towns in the interior, of which the only one worth mentioning is Cimmerion, now Eski-Krim, that is, Old Krim.

The earliest inhabitants of the peninsula appear to have been the Cimmerians, some of whom remained in it after the great body of the nation had been driven from their seats round the Palus Maeotis by the Scythians. (Herod., iv. 1, 11, 12.) Clear traces of this people remain in the names of Cimmerion, the Cimmerian Bosporus, the Cimmerian Chersonesus (as the peninsula was sometimes called), and in its modern names of Crimea and Crim-Tartary. In the earliest notices of the Chersonesus, by Greek writers, we find the mountainous region of the south and south-east inhabited by a piratical people, called

* This name was probably derived from a ditch which in very antient times ran across the isthmus, and which appears to have been fortified ever since. This ditch must not be confounded with that mentioned by Herodotus (iv. 120), which appears to have been in the peninsula itself, and at the eastern part of it. (Niebuhr's *Vermischte Schriften*, i., p. 157; Bähr's note on the passage in Herodotus, iv. 3.)

the Tauri, from whom the Chersonesus was called Tauriea, and whose name remains in that of the modern Russian province of Taurida, in which the Crimea is included. Who these Tauri were is a question of some difficulty. Strabo (p. 308) calls them a Scythian people, but Herodotus (iv. 99) clearly distinguishes the Tauri from the Scythians, as being a different nation. The inhabitants of the whole or a part of the peninsula are not unfrequently called Scythotauri or Tauroscythae. Judging from this mixed name, from the testimony of Herodotus to the two facts that the Tauri were a different people from the Scythians, and that the Scythians did not drive out all the Cimmerians from the peninsula, and, lastly, from several analogous cases,* it seems most probable that the Tauri were a remnant of the old Cimmerian inhabitants, who had maintained themselves in the mountains against the Scythian invaders. The name 'Tauri' is supposed to be derived from an old root 'Tau,' meaning a mountain. The Tauri were reputed by the Greeks to be inhospitable and cruel to strangers: they were said to offer human sacrifices, especially of shipwrecked mariners, to a virgin goddess, whom, according to Herodotus, the Tauri themselves identified with Iphigeneia, the daughter of Agamemnon, and whose temple stood on the promontory of Parthenion. (Herodot., iv. 103; Strabo, p. 308; Mela, ii. 1; Diod. Sic., iv. 44.) This legend enters into the composition of the 'Iphigeneia in Tauris' of Euripides, and is several times referred to by the Roman poets.

From about the sixth century before Christ downwards, several Greek colonies were planted on the Chersonese, and these were gradually formed into two states, that of Chersonesus, comprehending the smaller peninsula on the south-west, and the kingdom of Bosporus on the south-east. These two states were united under Mithridates. [Bosporus.]

Further information respecting the geography and history of the peninsula and of the adjoining delta of the Kuban is given under Crimea and Taman.

TAURI'DA, one of the governments of South Russia, sometimes called the government of Simferopol, situated on the Black Sea, consists of—1st, the Crimea or Taurie Peninsula; 2nd, the Nogay Steppe, with the island of Taman [Taman]; 3rd, the country of the Tschernomorsk Cossacks. It is bounded on the north-west by Kherson, on the north-east by the country of the Don Cossacks, on the east by Caucasia, on the south-east by the Kuban, and on the south by the Black Sea. The Crimea and all its principal towns are described under the respective heads. [Baktschisarai; Crimea; Kaffa; Sebastopol; Simferopol.] The area of the whole is 35,000 square miles, with 520,000 inhabitants of many different nations, Tartars, Cossacks, Russians, Jews, Gypsies, Germans, and other foreign colonists, &c. It lies between 44° 30′ and 47° 50′ N. lat., and between 31° 25′ and 40° 25′ E. long. The Nogay Steppe includes the whole of the extensive country from the Dnieper and its limans to the Buda. It is a dry elevated steppe on a basis of granite. The country has precisely the character of a Russian steppe: the soil is dry, poor, in part sandy, and saltish, without wood; but there are here and there extensive hollows with rich black mould, which produce the finest grass. The climate is extremely mild, and differs little from that of the peninsula. The winter, though short, is severe. The only rivers are those which form the boundaries: the Dnieper on the north-west, the Konski Wodi on the north, and the Buda on the east. On the south-east is the Sea of Azof, and on the west the Black Sea.

The land of the Tschernomorsk Cossacks including the island or peninsula of Taman, is bounded on the north by the country of the Don Cossacks, on the east by Caucasia, on the south by the river Kuban, and on the west by the Sea of Azof, and is separated from the Crimea only by the strait of Yenikale, which connects the Sea of Azof with the Euxine. The coast is sandy, flat, and forms some considerable bays or inlets, called by the Russians limans, the most considerable of which is the Besugakoi, nearly in the middle of the country. It is an immense plain, with a few hills in the south, belonging to the Caucasian system, consisting in general of very fertile lowlands, which are well adapted for agriculture, but are for the most part used as pasture for cattle: the remainder consists of a poor saline soil; and there are some small lakes with salt water: the climate is very mild. The principal rivers are the Kuban, on the south, which separates it from Circassia, and discharges itself on the south of Taman by a very broad liman, and the Iega, on the north frontier next the country of the Don Cossacks, which is joined by several small streams, and empties itself by a considerable liman into the Sea of Azof. The small streams in the interior fall into the Sea of Azof, one of which, the Besuga, forms at its mouth the liman Besugakoi.

The countries forming the government of Taurida were inhabited in antient times by the Scythians and by Greek colonists. Since the time of Herodotus, in the fifth century B.C., they have been successively conquered and ravaged by many different nations. They have been subject to the kings of the Bosporus, the Romans, the Sarmatians, then to the Greek emperors, and at the end of the twelfth century partly to the Genoese; they were conquered in the thirteenth century by the Tartars, and at the end of the fifteenth by the Turks. Mohammed II. made himself master of Taurida in 1475, and expelled the Genoese and the Venetians, the former of whom possessed Kaffa and Kherson, and the latter had the colony of Tana. Subsequently to 1698 the Russian armies repeatedly penetrated into the Crimea, the inhabitants of which often made predatory ineursions into the neighbouring countries. It was not however till 1771 that the country was really conquered by Dolgorucky, and the Porte compelled, in 1774, at the peace of Kutschuk-Kainardji, to recognise the Crimea as an independent country, to be governed by a khan chosen by the nation, and to recognise the sultan as their head in religious matters only. The khan Sahen Ghierai, whose election had been supported by the Russians, being pressed by the Turkish party, was at length induced to seek refuge in St. Petersburg. Russia now declared the Crimea to be her property, and the Porte, to avoid a new war, ceded it wholly to Russia, in January, 1784. The khan received a pension from Russia, and in the sequel retired to Turkey, but in 1787 was beheaded in the Isle of Rhodes by the sultan's order. Sultan Kalli Ghierai is his lineal descendant, who lives (or at least did live some years ago) in Simferopol, is a Christian, and is married to a Scotchwoman. The Crimea and the provinces dependent on it were formed into a government in 1784, by the name of Taurida, and incorporated with the Russian empire. The empress Catherine II. added to the imperial titles that of Czar of the Tauric Chersonese, and conferred on Prince Potemkin, who had been instrumental in bringing about, not without violence, the submission of the Tartar inhabitants, the surname of the Taurian. The Porte indeed appointed a new khan in 1786, and demanded that the Crimea should be replaced on the footing stipulated in the last peace; but it was obliged to cede it for ever to Russia in the peace of 1792. Taurida was at first a province of the government of Ekaterinoslav; in 1797 it was incorporated with the government of New Russia; and in 1802 it was made a distinct government by the emperor Alexander.

Among the numerous authorities that might be quoted, besides those already cited under the heads of the Crimea, Odessa, &c., we may mention Muraview Apostol, *Reise durch Taurien*, 1820; Eichwald, *Alte Geographie des Kaspischen Meeres des Kaukasus, und des südlichen Russlands*, 1838; and for the Nogay Tartars, Daniel Schlatter, of St. Gallen, *Bruckstücke aus eigenen Reisen nach dem südlichen Russland in den Jahren* 1822-1828.

TAURINE, a peculiar crystallizable substance contained in the bile. Its properties are, that it has the form of a six-sided prism terminated by pyramids of four or six faces; the crystals are gritty between the teeth, and have a sharpish taste, which is neither sweet nor saline; they undergo no alteration by exposure to the air even at 212°, and have neither an acid nor an alkaline reaction. When heated in the naked fire, this substance becomes brown, fuses into a thick liquid, swells up, exhales a sweetish empyreumatic odour resembling that of burning indigo, and leaves a charcoal, which is readily burnt: when submitted to dry distillation, it yields much thick brown oil, and a little yellow acidulous water, which holds

* For example, in our own island the very same thing has happened to a people whom some think (on account of their name) to be a branch of this very Cimmerian family, the Cymry, who, in the mountains of Wales, successfully resisted the Saxon and Norman invaders.

an ammoniacal salt in solution, and reddens a solution of perchloride of iron; one part requires 15½ parts of water at 54° for solution; it is much more soluble in boiling water, and the excess crystallizes on cooling; it is but little soluble even in boiling alcohol of sp. gr. 0·835, and is nearly insoluble in absolute alcohol. Concentrated sulphuric acid dissolves and forms a light brown solution with taurine; nitric acid readily dissolves it, and when the acid is evaporated, it is left unaltered.

TAURIS. [Tabriz.]

TAUROME'NIUM, now TAORMI'NA, a town in the northern part of the east coast of Sicily. The antient name, Tauromenium (Ταυρομένιον), like that of the river Tauromenius (the modern Aleantara), at the mouth of which the town was situated, was derived from Mount Taurus, on which the town was built. Diodorus Siculus gives two apparently contradictory accounts of its foundation, though both agree in the main point, that Tauromenium was founded by the inhabitants of the antient town of Naxos, which lay a few miles south of Tauromenium. In one passage (xiv. 59) he states that during the war of Dionysius the Tyrant with Himilco, the latter induced the Siculi, who had previously received from Dionysius the town of Naxos and its territory, to occupy Mount Taurus, and to fortify themselves there; and after the termination of the war in favour of the Carthaginians, the Siculi, about 392 B.C., formed a permanent settlement on Mount Taurus, which they called Tauromenium. The other account (Diodor. Sic., xvi. 7) places the building of the town somewhat later, inasmuch as it states that it was founded by Andromachus, the father of Timaeus the historian, in conjunction with the inhabitants of the destroyed town of Naxos; but in this account Andromachus himself is called a Tauromenian, which implies the previous existence of Tauromenium. Consequently Diodorus can only have meant to say that Andromachus assigned to the homeless Naxians habitations in the already existing town of Tauromenium, and that he agreed with them in the name of Tauromenium being preserved. (Wesseling ad Diodor. Sic., vol. vi., p. 552, ed. Bipont.) Strabo (vi., p. 27, ed. Tauchnitz) calls Tauromenium a colony of the Zanclæans of Hybla. Soon after its foundation the new town appears to have become very wealthy and powerful. Agathocles, the tyrant of Syracuse, put to death a great number of the inhabitants who had opposed his usurpation. (Diodor. Sic., xix. 102.) In the time of Pyrrhus the town was governed by a tyrant, Tyndarion, who supported the king on his landing in Sicily. After the subjugation of Sicily by the Romans, Tauromenium became a 'civitas foederata;' and being thus under the immediate protection of Rome, it enjoyed a long peace, during which its prosperity increased. (Cicero, *In Verrem*, ii., 66.) In the time of Verres the town contained many statues of this propraetor, all of which, after his departure, were destroyed, except the pedestal of one which stood in the market-place, which was left standing to mark the disgrace of the Roman governor. In the war of Cæsar with Pompey, Tauromenium was in the possession of the Pompeian party; but when Cæsar made himself master of it, he expelled the inhabitants, and established a Roman colony there. (Appian, *De Bello Civili*, v. 103, 105, 109; Pliny, *Hist. Nat.*, iii. 14; Velleius Paterc., ii., 79.)

Taormina at present contains about 6000 inhabitants: its situation on a steep rock on the sea-coast is magnificent. It contains considerable ruins of antient buildings, especially a theatre of gigantic dimensions, the seats of which are cut in the rock, which projects into the sea. This theatre and the aqueduct, or, as it is generally called, a naumachia, of which there are remains, were not constructed till the time of the empire. On the hills which rise above Taormina there are ruins of several castles, and among them one is very remarkable, which is called Mola, and was built in the ninth century of our æra by the Saracens, who took the town by storm after a long and brave resistance by the inhabitants.

The principal deity worshipped by the antient Tauromenians was Apollo, which confirms the statement that the town was a settlement of the Naxians, among whom Apollo was the national divinity. An Apollo, with a wreath of laurel round his head, occurs on many coins found at Tauromenium, with the inscription ΑΡΧΑΓΕΤΑ, or ΑΡΧΑΓΕΤΑΣ; and the reverse shows a tripod, which probably indicates that Naxos was founded under the sanction of the Delphic god. Other coins show the head of Dionysius or of Athena. There is one coin, one side of which represents a head of Jupiter, and the other an eagle with the thunderbolts. The name of the town is expressed on the coins by Ταυρο, Ταυρομ, Ταυρομιτ, or Ταυρομενιταν. (Eckhel, *Doctrina Num.*, i., part i., p. 247, &c.; Mionnet, i., p. 324, &c.; *Supplem.*, i., p. 448, &c.)

TAURUS, MOUNT (ὁ Ταῦρος), in the opinion of the later Greek geographers, was a great chain of mountains which extended nearly due east and west from the shores of the Ægean to those of the supposed Eastern Ocean, and divided Asia into two parts, Asia within the Taurus (ἐντὸς τοῦ Ταύρου), and Asia without the Taurus (ἐκτὸς τοῦ Ταύρου). Their notions respecting this chain were by no means accurate, and indeed only a small part of it ever really bore the name.

The chain of Taurus, properly so called, commences at the south-western point of Asia Minor, and proceeding eastward parallel and near to the Mediterranean, it encloses between itself and the coast the narrow strip of land which formed Pamphylia and Cilicia. At the river Pyramus the chain divides into two, that of Amanus, which proceeds to the east, dividing Syria from Asia Minor [Amanus], and the continuation of Taurus, which runs north-east, along the south-east side of Cappadocia, across the Euphrates into the northern part of Armenia, where it joins Mount Masius. This chain now bears the name of Enamas, Ramadan, and Gourin.

In Cappadocia the Taurus throws off a great branch which was called the Anti-Taurus (ὁ Ἀντίταυρος), and which passes through the middle of Cappadocia, north-east to the sources of the Halys, and thence east to the Euphrates. Its modern name is Alidagh. At Sebaste (Siwas) this chain joins that of the Paryadres (Chisheshi), which extends north-east as far as the mountains of Ararat. In modern geography the whole chain from the south-west of Asia Minor to Ararat bears the name of Taurus. The name itself is probably merely a form of a root which occurs in several Oriental languages, meaning mountain.

(Rennell's *Geography of Herodotus*, i. 228, &c.; Schirlitz's *Alte Geographie*.) [Anatolia.]

TAURUS (the Bull), the second constellation of the Zodiac. Its position in the heavens, surrounded by Aries, Eridanus, Orion, and Perseus, is easily obtained by the manner in which its bright star Aldebaran is connected with the belt of Orion. In all speculations upon the origin of the zodiac, Taurus must be an important object of consideration, since, at the earliest date which prudent speculation can consider it advisable to begin from, Aldebaran must have been at no great distance from the vernal equinox. Referring this point however to the article on the zodiac, we shall merely notice that the Greeks, as usual, attribute but a paltry mythological origin to this striking constellation; the fables of Europa and Io being the only ones alluded to in statements of its mythological meaning.

The figure is only a part of a bull, the head, shoulders, and fore legs. Aldebaran and the Hyades form the forehead and eye, and the Pleiades are in the shoulder. But Aratus must have drawn the figure differently, for he puts the Pleiades in the knees.

The Hyades form a group, of which five (some of the antients said seven) are distinctly visible to the naked eye, α, θ, γ, δ, and ϵ of the constellation: there are many more in the cluster. These stars are arranged in the form of a V, α and ϵ being the extremes, and γ at the angular point. The star α is Aldebaran. The name seems to be derived from ὕειν, to rain. The Latins called them *suculæ* (little pigs, no doubt meaning Aldebaran for the sow, and the others for her offspring), a name which Cicero and others state to have arisen from supposing the Greek word to have been from ὗς (pigs), and not from ὕειν. We think however it may be possible that they were right in their idea of the Greek word: the large star and the cluster of small ones might very easily suggest the notion of a sow and her litter.

The Pleiades are so close a group of stars that it is very difficult to say how many are seen by the naked eye. 'They are called seven,' says Higinus, 'but no one can see

more than six:' and six seems to be the number generally visible, though there are many more in the cluster. These stars are 17, 19, 20, 23, 25, and 26 of Flamsteed. There is accordingly a supposition that some one star, once visible, has now changed its magnitude, or disappeared altogether. The name has been derived from πλεῖν, to sail. One of the mythological stories makes these stars the daughters of *Pleione* and Atlas.

The principal stars of Taurus are as follows: (*g*), (*b*), (*m*), (*e*), (*c*), (*d*), (*f*), (*h*) are not Bayer's letters, but Flamsteed's, by which he distinguished stars in the Pleiades.

TAURUS PONIATOWSKI, a constellation formed by the Abbé Poczobut, a Polish astronomer (born in 1728: we do not know the year of his death; but Lalande mentions his having resumed his observations at Wilna in 1802), in honour of the reigning king of Poland, and adopted in the French (Fortin's) edition of Flamsteed's maps (or rather added to the plates). Poczobut, in 1778, proposed this constellation to the French and other academies, by whom it was received. Bode conjectures that a resemblance of certain very small stars in it to the figure of the Hyades was the reason for the first word of the name. It is situated between Aquila and Ophiuchus, and the Astronomical Society's Catalogue mentions one star of it, of the sixth magnitude, being 2070 of that catalogue, and (328) of Piazzi.

TAUSAN, TAUSSEN, or TAGESEN, JOHN, the first Danish theologian who made his countrymen acquainted with the principles of the Lutheran reformation. He was born in 1494, at Birkinde, a village in the island of Fünen. After he had received his early education in the convent of Antworskow, he wished to continue his studies at some university, and the abbot of the convent fixed upon Cologne. Here he became accidentally acquainted with some of the earliest works of Luther, which excited in him such a desire to study under the reformer, that he defied the opposition of his superiors, and went to Wittenberg. After having spent some time here he went to Rostock, where he took his degree of M.A., and thence proceeded to Copenhagen, to undertake the office of teacher in one of the public schools, 1521. This sphere of action however did not satisfy him: his wish was to proclaim the new doctrines, which he thought he could do more effectually if he withdrew to his former convent of Antworskow. Here he gained great reputation as a preacher, and at first endeavoured privately to make his brother monks acquainted with the reformed doctrines; but in 1524, on the occasion of the abbot being absent, Tausan delivered a sermon, which produced such an effect on his hearers, that most of the monks declared themselves ready to abandon their old belief. The excitement and disturbance arising from such proceedings led to Tausan being transferred to another convent at Wiborg, where however he persevered in his exertions, and again gained a considerable number of followers. King Frederic I. of Denmark, who was favourably disposed towards the doctrines of the German reformers, and wished to favour Tausan, sent him, in 1526, a letter of protection, gave him the title of court preacher, and assigned to him a church at Wiborg, where he might preach without molestation. The bishop of this place opposed him in everything; but his attempts were fruitless, as Tausan was supported by the sympathy of the people. The disputes between the two religious parties now became more vehement every day; and at last the king, in order to save Tausan, invited him, in 1529, to Copenhagen, where he was appointed preacher to the church of St. Nicolas. The reformation in Denmark, the seeds of which had thus been sown, made gradual and steady progress; and in order to settle the question permanently, the king issued a command that deputies of the Roman Catholics and Protestants should appear on the 8th of September, 1530, before the assembly of the states, and explain their creeds and points of dispute. Tausan and the principal men of his party were present, and it was finally settled that the Protestants should preach and propagate their doctrines. The tranquillity thus restored was interrupted by the king's death in 1533, when the Roman Catholic party, and more especially the bishop of Roeskilde, again began to trouble Tausan, who was on the point of being driven out of his country. For a time he absented himself from Copenhagen; but Protestantism in the meanwhile made such progress, that the opposition to it in a short time either ceased or became very weak. In 1537, in which year John Bugenhagen was sent by Luther to Denmark to assist in arranging the ecclesiastical affairs of the country, Tausan was appointed preacher and lecturer on theology at Roeskilde; and four years later he was made bishop of Ripen, an office which he held until his death, on the 9th of November, 1561.

Tausan wrote a considerable number of theological works in Danish: some of them are controversial, others exegetical, and a third class consists of translations of portions of the Scripture and of original hymns. His works, as well as the history of his life, show that he was a simple and straightforward man; but in talent he was far inferior to the great reformers who were his contemporaries.

TAUTOCHRON. [Time of Descent.]

TAUTOLITE, a mineral which occurs crystallized. Primary form a right rhombic prism. Fracture conchoidal, uneven. Hardness 6·5 to 7. Very brittle. Colour velvet black; streak grey. Lustre vitreous. Opaque. Specific gravity 3·865.

Before the blow-pipe on charcoal, melts into a blackish scoria, which is attracted by the magnet: with borax it forms a clear green glass.

It does not appear to have been accurately analyzed, but is stated to be probably silicate of protoxide of iron, and silicate of magnesia. It is found in the volcanic rocks of the Lake of Laach, near Bonn, on the Rhine.

TAVERNIER, JEAN BAPTISTE, BARON D'AUBONNE, the son of an Antwerp engraver who had settled at Paris and dealt in maps, was born in 1605. He was a traveller from his boyhood. The sight of the maps with which he was surrounded and the conversation of the geographers who frequented his father's shop inspired him with a passion for seeing foreign countries, which he soon contrived to gratify, it does not very clearly appear by what means or in what capacity.

Between 1620 and the close of 1630 he visited most of the countries of Europe: this may be considered as his apprenticeship to the profession of a traveller. Between 1630 and 1669 he made six journeys to the East: this was the portion of his life devoted to productive toil. The story of the remainder of his life, from 1670 to 1680, impresses us with the idea of an elastic and untired spirit, which, stimulated in part by his dilapidated fortune, but still more by an incapacity of repose, sunk in an attempt to re-enter that world of active exertion in which his place had been occupied by younger men. To appreciate Tavernier, it is necessary to examine his character as it displayed itself in each of these three periods.

He appears to have left his paternal home before he had completed his fifteenth year; for he tells us that after visiting England, Antwerp, Amsterdam, Frankfort-on-the-Main, Augsburg, and Nürnberg, he was induced, by what he heard at the last-mentioned place of the mustering of armies in Bohemia, to repair to the theatre of war. About a day's journey from Nürnberg, he met Colonel Brener, son of the governor of Vienna, who took him into his service. Tavernier was present at the battle of Prague, 8th November, 1620. Some years later, he followed his master to Vienna, and was presented by him to his uncle, the governor of Raab, at that time viceroy of Hungary, who received the young Frenchman into his family in the capacity of a page. With this nobleman Tavernier remained four years and a half, and ultimately obtained his dismissal with a view to entering the service of the Prince of Mantua. Something appears to have made him change this determination, for after a brief stay in Mantua he left it, about Christmas, 1629; and after making a short tour in Italy, and visiting his friends at Paris, returned to Germany. During the summer of 1629 he made an excursion into Poland; on his return from which he attached himself for a short time to the family of Colonel Butler, 'who afterwards killed Wallenstein.' Hearing a report that the son of the emperor Ferdinand II. (afterwards emperor himself, with the title Ferdinand III.) was to be crowned king of the Romans in Regensburg, Tavernier who had been present at that prince's election as king of Hungary (1625) and his coronation as king of Bohemia (1627), wished to be present at this third solemnity also, and with this view threw up his appointment (whatever it was) in Butler's household.

Tavernier has nowhere explicitly stated what were his rank and occupations while he led this unsettled life. No expression escapes him to intimate that he at any time found himself at a loss for money. The appointment of page in the family of a nobleman holding the high office of viceroy of Hungary was generally the first step to the command of a troop. Yet there is a vagueness in the language of Tavernier while speaking of this part of his history, which leads us to suspect that his station was more of a menial character. His lively and enterprising disposition seems however to have made him a general favourite, and his power of expressing himself—not very elegantly, if we are to judge from his French, yet intelligibly—in several European languages, rendered him an eligible attendant. His position was most probably that of one of the ready-handed, quick-witted, not over-scrupulous attendants, with whom men of high rank in that age found it necessary to surround themselves. From hints dropped in different parts of his travels, it is highly probable that he had picked up some money in the wars; he had acquired some knowledge of the military art; he knew something of watch-making and jewellery; and, above all, he had learned to shift for himself. Beyond such a general acquaintance with maps and geography as he had picked up in his father's shop, he possessed no literary or scientific attainments; and his tastes and habits were those of the young rufflers of his age. A naturally frank and kindly though somewhat boisterous temper had done much to neutralize the worst impressions of the lax school in which he had been educated.

After such preliminary training, and with a character thus far developed, Tavernier commenced his travels in the East. He had already been turning his eyes in that direction, and making interest to be received into the suite of a new ambassador the emperor was about to despatch to the grand seignior, when the confidential agent of Richelieu, Father Joseph, who had known him at Paris, proposed that he should accompany two young French noblemen who were travelling to Palestine by the way of Constantinople. Tavernier closed with the offer, and in company with his employers reached that city during the winter of 1630-31. A recent biographer has stated that he began his first journey in 1636: the origin of the mistake is as apparent as that it is a mistake. Tavernier says 'after the ceremony of the coronation was finished,' and Ferdinand III. was not crowned king of the Romans till December, 1636. Tavernier gives no dates in the account of his first journey; but we know that he embarked at Marseille for his second in September, 1638; and we also know that he arrived at Rome on his return from his first voyage on the day of Easter. He was detained eleven months at Constantinople waiting for a caravan, and seven weeks by a severe attack of sickness at Aleppo: so, if we assume he set out from Regensburg in December, 1636, we have only three months left for the overland journey from Regensburg to Dresden, Vienna, Constantinople, Erzroum, Tabriz, Ispahan, Bagdad, Aleppo, and Scanderoon, and the voyage from Scanderoon to Rome. It is impossible that Tavernier's first journey could have been subsequent to Ferdinand's coronation as king of the Romans. But a strong effort was made by that prince's father to have him crowned at the close of the diet held at Regensburg in 1630; and Tavernier, writing from memory forty years later, may have imagined that the festivities he witnessed at that time were in honour of a coronation which was expected to take place, but did not. Two passages in his Travels seem to place it beyond a doubt that the visit to Regensburg which led to his first journey took place in 1630. In his first volume (p. 689 of the Paris edition of 1676) the expression occurs—'in 1632 on the road from Ispahan to Bagdat.' He only travelled that road once, and that was on his return from his first expedition into Persia. It would be unsafe to rely upon the evidence of a figure in a book not very correctly printed; but in the account of his first journey to Ispahan he mentions having seen at Tocat the vizir, who was executed a few days later, after being obliged to raise the siege of Bagdad. This can only refer to Khosrew pasha, executed there about the end of April, 1632.

This date being ascertained, the chronology of the ensuing forty years of Tavernier's life may be gleaned from his travels with tolerable accuracy. He began his first journey to the East from Regensburg, in December, 1630; penetrated by way of Constantinople and Tabriz to Ispahan, and returned by Bagdad and Aleppo to Europe early in the summer of 1633. From this date till the commencement of his second voyage his history would be a complete blank, had he not told in a parenthesis that he was appointed comptroller in the household of the due d'Orléans, who gave him leave of absence during his journeys to the East. On the 13th of September, 1638, he embarked at Marseille in a Dutch vessel, and landing at Scanderoon, proceeded by way of Aleppo and the Great Desert west of the Euphrates to Basra. There he embarked in a vessel sailing to Ormuz, and landing at Bushire, proceeded through Shiraz to Ispahan. After some stay in that capital, he travelled by Shiraz and Lars to

Gombroon, where he embarked for Surat. He visited Agra on this occasion; but here again we are at a loss for dates to enable us to trace his routes. We only know that he passed through Burhampore on his return from Agra to Surat in 1641; that he visited Goa and returned to Surat by land about the end of that year; and that he was at Ahmedabad, either going to or returning from Agra, in 1642. That he had revisited Ispahan in the interval is not improbable, since he says that 'for six journeys which I have made between Paris and Ispahan, I have made twice as many from Ispahan to Agra and other parts of the Great Mogul's dominions.' He was at Ispahan towards the close of the year 1642; and probably soon after returned to France. On his third voyage he took with him the brother already alluded to, and left Paris on the 6th of December, 1643. This time, after visiting Ispahan as usual, he embarked at Gombroon for India. In January, 1645, he left Surat on an excursion to the diamond-mines near Golconda. In January, 1648, he made a voyage by sea to Goa; and in April of the same year he embarked at Mingvela for Batavia; whence he returned to Europe in the Dutch fleet in 1649. Tavernier's fourth journey occupied him from the 18th of June, 1651, when he set out from Paris, till 1655. On this occasion he proceeded from Persia to Masulipatan, in May, 1652; he revisited the diamond-mines near Golconda in 1653, and in 1654 he travelled from Ormuz to Kerman, and after spending three months there, took the route of Yezd to Ispahan, and returned to Europe by Smyrna. His fifth journey was begun in February, 1656. He was at Agra in 1659, but we are at a loss for other dates in this journey. The sixth and last expedition that Tavernier made to the East was begun in November, 1663, and was terminated in 1669. The most important novelty of this journey was his tour through the province of Bengal as far as Dacca, which occupied him from November, 1665, till July or August, 1666. He was at Ispahan in July, 1667, and on his return to Europe visited Constantinople for the second time.

The very unsatisfactory arrangement adopted in the narrative of Tavernier's journeys has rendered it advisable to extract from it the preceding incomplete chronology of them. His first publication was an account of the interior of the seraglio at Constantinople (*Nouvelle Relation de l'Intérieur du Serrail*), published at Paris, in a thin 4to volume, in 1675. This was followed by an account of his travels (*Six Voyages en Turquie, en Perse, et aux Indes*), also at Paris, in two quarto volumes, in 1676. A third volume was added in 1679, containing an account of Japan and the origin of the persecution of the Christians in these islands; an account of the proceedings of the deputies from the king and the French company of the Indies both in Persia and India; observations on the commerce of the East Indies; account of the kingdom of Tunquin; account of the conduct of the Dutch in Asia. In preparing the account of the Seraglio and the two first volumes of his Travels, Tavernier employed Chappuzeau, a dull and unintelligent writer: the memoirs contained in the third volume were prepared by Lachapelle, secretary to the president Lamaignon. The account of the seraglio, and the contents of the third volume of the travels, are partly memoirs compiled from the information of others, and partly more full expositions of topics touched upon in his narrative. It is to the first two volumes of Tavernier's travels that we must look for such information of the countries he visited, the time he spent in them, and the adventures he encountered, as is necessary to enable us to determine what he witnessed himself, what he learned from the report of others, how far his informants were worthy of belief, and how far he was qualified to understand their communications. But the arrangement of these two volumes is the very worst that could be conceived for supplying satisfactory information upon these heads. The first volume professes to give an account of the various routes by which the Parisian traveller can reach Constantinople, Ispahan, and the Persian Gulf. It is arranged as a *routier;* the result of all Tavernier's observations upon each line of road is given at once, and it is only from incidental remarks that we learn when and in what direction he travelled it. His remarks upon the customs, government, and commerce of the different countries are thrown into intercalary chapters. A similar arrangement is adopted in his second volume, which contains the fruits of his observations in the south of India, in the region between Surat and Delhi, in Bengal, and in the Dutch possessions in the Eastern Archipelago. The work is neither a systematic account of the geography and statistics of the countries in which Tavernier travelled, nor is it a personal narrative of the traveller. It is an ill-digested and unsatisfactory attempt to combine both.

Yet are the four volumes we have mentioned full of available matter, both for the historian and the geographer. The former will find in it the fruits of the forty years' experience and observation of a European merchant in Turkey, Persia, India, and the Indian Archipelago, in the seventeenth century. Tavernier did not possess either the intellect or the education of Thévénot and Bernier, but his opportunities of observation were more varied and protracted. He was a part of that commercial enterprise and rivalry of which they were only spectators. He is himself a specimen of the kind of adventurers who at that time managed the commerce of Europe with the East. His unconscious revelations of his own character may be relied upon, and the naïveté with which they are made encourages us to believe what he tells us of others. His statements have not passed unchallenged: they wounded the national pride of the Dutch too sore to be left without a reply, and the partisan feelings of the Protestant literati of Europe induced them to embrace the cause of Holland, in opposition to the *protégé* of Louis XIV. Even the Catholic literati took little interest in a writer who frankly confessed that he saw nothing interesting or valuable in the plain of Troy or the ruins of Persepolis. And yet notwithstanding the violent attacks of the Dutch and Calvinist writers, the silence of others, and even of himself (for Tavernier did not engage in a controversy), not one material assertion he made has been disproved. Unfriendly criticism has been confined to the remark that many of his statements regarding the Dutch are trivial, and betray a littleness of mind: this may be, but they are not the less characteristic for that reason. Tavernier's accounts of the principal objects of Oriental commerce in his day, of the leading markets and routes of trade, of the money of the different countries, and the state of the exchanges, are more full and intelligible than those we find in any other cotemporary writer. His success in trade affords a guarantee of the correctness of the opinions he states. We have collated his routes, whenever this was possible, with those of recent travellers, and have found them in general so accurate, that they may be relied upon for the purposes of comparative geography, and in one or two instances as affording information regarding tracts which have not been visited since his time. Tavernier's notices of the route from Casvin to India by Candahar, and of the provinces to the north of Erivan, leave a favourable impression of his talent for extracting information from the native authorities. He has been accused of plagiarism, principally because of the striking coincidence between his account of the Guebres of Kerman, published in 1676, and that which Louis Moreri published in 1671 from the papers of Father Gabriel de Chinon. It deserves to be noticed that Moreri's publication is lucidly arranged and neatly expressed, while the account contained in Tavernier's travels is confused and miserable in point of diction. Had it been taken from Moreri, it is scarcely possible that the latter could have been so wretchedly composed. Add to this that the information found in the papers of Father Gabriel is not said to have been the fruit of personal observation; that Tavernier resided three months among the Guebres at Kirman, and had frequent dealings with them in India and elsewhere; that he and Father Gabriel repeatedly met in Persia; and it must be allowed that the priest is quite as likely to have derived his information from the merchant as otherwise. In judging of the statements made by Tavernier, the school in which he was trained, and his personal character as it appears from his own story, must always be kept in view. He had no knowledge of or taste for science and literature, for art, or antiquarian research. He acted upon impulse, and his instincts were love of travelling, and desire to acquire money for the sake of spending it in feasting and personal display. A diamond was a more interesting object to him than the mysterious remains of Tchelminar. He had no very nice or refined sense of honour, but he was frank and veracious, and little inclined to deck himself with stolen feathers of literature; possibly because he could not appreciate their value.

In this review we have been obliged to anticipate that part of the history of the third period of Tavernier's life, which relates to what may be called his literary labours. We are thus enabled to abridge the sequel of our narrative. On Tavernier's return from his sixth journey he was presented with *lettres de noblesse*, by Louis XIV., and purchased about the same time the barony of Aubonne in the Pais de Vaud. When his travels were published, they were, as has been intimated above, fiercely attacked; in particular, most virulently by Jurieu, in his 'Esprit de M. Arnauld' (December, 1684); more temperately and with a greater parade of evidence by Henrick van Quellenburgh, in 'Vindiciæ Batavicæ' (Amsterdam, 1684). Tavernier made no reply. Bayle has given a characteristic account of his conduct relative to the publication of Jurieu, which was rather a libel than a criticism. 'He made a noise in the taverns and streets, he threatened and even named the day and hour when he would apply to the Walloon consistory of Rotterdam to demand execution of the canonical laws against the minister who had dishonoured him: but his threatenings came to nothing, he retired very peaceably, and never commenced any persecution at all.' The misconduct of a nephew, to whom he had intrusted the management of his affairs in the Levant, obliged him to sell, some time previous to 1688, his hotel in Paris and his estate of Aubonne. He retired first into Switzerland, and subsequently to Berlin, where he was nominated by the elector of Brandenburg director of a projected East India Company. From the time of his first journey he had regretted being prevented from carrying into execution a design which he then entertained of returning from Persia through the Russian dominions. His new appointment afforded him an excuse and opportunity for making that journey, and he set out to travel to the East Indies across Russia in 1688. He was taken ill at Moscow, and died there in the month of July, 1689. The equivocal conclusion of Boileau's inscription on Tavernier's portrait contains a fair enough estimate of his character:—

> 'En tous lieux sa vertu fut son plus sûr appui;
> Et bien qu'en nos climats de retour aujourd'hui
> En foule à nos yeux il présente
> Les plus rares trésors que le soleil enfante;
> Il n'a rien rapporté de si rare que lui.'

(*Les six Voyages de Jean Baptiste Tavernier, Ecuyer Baron d'Aubonne, en Turquie, en Perse, et aux Indes*, à Paris, 1676-9, 4to.; *L'Esprit de M. Arnauld, tiré des écrits de lui et de ses disciples*,' Deventer, 1684, 12mo.; Henrick van Quellenburgh's *Vindiciæ Batavicæ, ofte Refutatie van het Tractaet van J. B. Tavernier, Chevalier, Baron d'Aubonne*, Amsterdam, 1684, 4to.; Bayle, *v.* 'Tavernier;' *Biographie Universelle*, *v.* 'Tavernier, Jean Baptiste,' par Weiss.)

TAVISTOCK, a parliamentary borough and market-town, on the south-western border of Devonshire, 207 miles from London, 34 from Exeter, and 11 from Plymouth. The parish extends between the western extremity of Dartmoor and the river Tamar, and, according to a survey made in 1781, comprises 13,987 acres, or nearly 22 square miles; but it is probable that this survey included lands within the boundary of the borough which are not in the parish: in the census of 1831 the area of the parish is stated to be 11,660 acres. The surface of the parish is diversified by hills from 300 to 600 feet in height, which rise in continued succession and are separated by valleys often deep and narrow, the general direction of which is from north-east to south-west. The higher ground towards Dartmoor is of granitic formation, and the neighbourhood of the town consists of schistose rock. The town is situated nearly in the centre of the parish, on the north-west bank of the Tavy, which here flows rapidly through a narrow valley, from which the ground rises steeply on both sides to the height of several hundred feet. The river is crossed by two bridges within the town. A narrow valley, or gully, from the north, is also covered by houses. The climate is variable, and the average quantity of rain falling in the year is 45 inches.

In 961 an abbey was founded at Tavistock, which was burnt by the Danes, and afterwards rebuilt on a larger scale. Henry I. (1100-1135) granted to the abbot a weekly market and a fair. In 1513 the thirty-fifth abbot was called to the House of Peers, but in 1539 his successor surrendered to the king, when the revenue of the abbey was estimated at 902*l*. A printing-press was established in the abbey soon after the introduction of the art into England. Fragments of the abbey still remain, but are chiefly incorporated with other buildings; and the refectory is used as an assembly-room. John, Lord Russell, ancestor of the Duke of Bedford, obtained a grant of the abbey lands. An antient lazar-house once stood on the site of the workhouse. The parish church is a spacious edifice, with a tower at the west end supported on arches. The interior consists of four aisles and a chancel, and contains some good monuments. The living is a vicarage, valued at 302*l*. per annum. The Independents, Unitarians, Quakers, and Wesleyan Methodists have places of worship. The date of the foundation of the grammar-school is not known, but in 1649 Sir John Glanville left an endowment for the education of one boy, which yields about 4*l*. per annum; and the Duke of Bedford, in whom the school-estate is vested, allows the master the use of a house rent-free besides other advantages, and 20*l*. a-year for the education of eight boys. There is a Lancasterian school chiefly supported by subscription, which in 1833 was attended by 135 boys and 88 girls. At the same period seventeen other schools were attended by 203 boys and 224 girls; and there were five Sunday-schools, in which 381 boys and 333 girls were instructed. There are two almshouses, one for four poor widows, who each receive 2*l*. a-year; and another for fifteen persons, nominated by the Duke of Bedford, who receive 3*l*. a-year each. A sum of 15*l*. is applicable to the apprenticing of poor children.

Tavistock returned two members to parliament previous to the passing of the Reform Act, a privilege which it had enjoyed since 1295 (23 Hen. I.). The right of election was in the resident freeholders. The Tavy formed the boundary of the borough on one side, and on the other its limits were defined by an artificial line. Under the Reform Act the borough was made co-extensive with the limits of the parish, the manor of Cudliptown excepted, and it still returns two members. The number of voters on the register, in 1840, was 347. Tavistock is not incorporated. The portreeve, who is elected annually at the court-leet of the lord of the manor, is the chief public officer, and makes the return of the elections. Tavistock is one of the polling-places for the county.

The parish registers of Tavistock from 1617 to 1836 have been made the subject of a more careful and elaborate examination than those of any other place in England. This task was undertaken by Dr. Barham, and the results are given in a series of tables which are printed in part ix. of the 'Tables' published by the Board of Trade; and an abstract of them is given in vol. iv., part 1, of the 'Journal of the London Statistical Society.' The population of the parish, in 1781, was 3117; in 1811, 4723; in 1821, 5483; in 1831, 5602. The increase between 1811 and 1821 is attributed to the extension of mining operations in the neighbourhood. There are some small manufacturing establishments. Tavistock is one of the four stannary towns in the county. In 1817 a canal was opened, which, after a course of 5 miles, 2 of which are under a tunnel, enters the Tamar at Morwell Ham quay. The head of the canal is connected with the quay by an inclined plane 240 feet high. This canal connects Tavistock with Plymouth. Sir Francis Drake was a native of Tavistock.

TAWI-TAWI. [Sooloo Archipelago.]

TAX, TAXATION. A tax is a portion of the produce and labour of a country placed at the disposal of the government.

Taxation is the general charging and levying of particular taxes by the government upon the community.

Objects of Taxation.

In a free state it is assumed that all taxation is necessary for the public good; if it is not necessary, the reason for it no longer exists. The amount of expenditure will in a great measure be determined by the magnitude of a state and by the number and importance of its political relations; yet the prudence with which its affairs are administered will affect the demands of the government upon the people, nearly as much as its necessities. The expenses of a private person must be regulated by his income; but in a state, the expenditure that is needed is the measure of the public income that must be obtained to meet it. A civilized community requires not only protection from foreign enemies and the means of internal security, but it needs various institutions of civil government conducive to its welfare, and which its wealth enables it to maintain

without an injurious pressure upon its resources. It is the business of a government to provide these, when proved to be necessary, in the best manner and at the least expense consistent with their efficiency.

The able and laborious committee of the House of Commons upon public income and expenditure in 1828 'unequivocally declared their full assent to the principle, that no government is justified in taking even the smallest sum of money from the people, unless a case can be clearly established to show that it will be productive of some essential advantage to them, and of one that cannot be obtained by a smaller sacrifice.' The committee truly added to the statement of this just principle, that 'nothing requires more wisdom and prudence than to fix the public expenditure at such an amount that the real wants of the people shall not be made to give way to any imaginary wants of the state: the latter arise from so many sources, that it is frequently very difficult to prevent the operation of an undue influence.' (*Second Report*, p. 4.) One of the first duties of representatives of the people is to watch with jealousy the expenditure of the public money. Every tax should be viewed as the purchase-money paid for equivalent advantages given in return. This principle assumes the necessity of moderation in levying taxes, and will scarcely be denied by any one when stated in that form; yet it is not uncommon to hear it argued that so long as taxes are *spent in the country*, the amount is not of consequence, as the money is returned through various channels to the people from whom it was derived. The principle we have just laid down at once exposes the fallacy of this doctrine, by reducing it to a simple question between debtor and creditor. For example, by paying a million of money every year, the people obtain the services of an army: this we will suppose to be an equivalent, and we will further assume that the food and clothing of the force are purchased, and that the entire pay of the men is spent, within the country. The whole of the money will thus be returned: but how? Not as a free gift, not as the repayment of a loan, but in the purchase of articles equal in value to the whole sum. The only benefit obtained by this return of the million is clearly nothing more than the ordinary profits of trade; for the community has already provided the money, and then out of its own capital and industry it produces what is equal to it in value, and this it *sells* to the state, receiving as payment the very sum it had itself contributed as a tax.

In whatever manner taxes may be expended, they must be regarded as injurious to the community. 'Every new tax,' says Mr. Ricardo, 'becomes a new charge on production, and raises the natural price. A portion of the labour of the country which was before at the disposal of the contributor to the tax is placed at the disposal of the state, and cannot therefore be employed productively.' (*Political Economy*, chap. xii., p. 206.)

General Principles of Taxation.

Having settled that taxation should be generally and in amount as light as possible, it must be determined upon what principles and in what manner taxes may best be levied. No other branch of legislation is perhaps so important as the wise application of just principles in the matter of taxation. The wealth, happiness, and even the morals of the people are dependent upon the financial policy of their government.

Adam Smith lays down four general maxims, which we shall briefly cite not only as being perfectly true in themselves and most valuable, but as proceeding from an authority so high that not to notice them might be accounted an omission.

I. 'The subjects of every state ought to contribute towards the support of the government as nearly as possible in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state.'

II. 'The tax which each individual is bound to pay ought to be certain, and not arbitrary. The time of payment, the manner of payment, the quantity to be paid, ought all to be clear and plain to the contributor, and to every other person.'

III. 'Every tax ought to be levied at the time or in the manner most likely to be convenient for the contributor to pay it.'

IV. 'Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state.'

In discussing the merits of particular taxes and classes of taxes, we shall have to consider with some minuteness the application of Adam Smith's first maxim. Its justice requires no enforcement or illustration, although unhappily the object is most difficult of attainment. The second maxim is of great importance, and the necessity of adhering to it must be universally acknowledged. Uncertainty gives rise to frauds and extortion on the part of the tax-gatherer, and to ill-will and suspicion on that of the contributor, while it offers a most injurious impediment to all the operations of trade. Notwithstanding the many evils of uncertainty, it is by no means an uncommon fault even in modern systems of taxation. We would pass over the practices of Eastern despotisms, where uncertainty and caprice prevail instead of fixed rules, but that the vices of their taxation are so exaggerated as to show the evils of a departure from just principles in the broadest light. All taxation is forbidden by the Koran, and although the prohibition has been evaded and broken through by the Turkish government in particular instances, it has always been an obstruction to any general system of imposts. In the absence of regular taxes, partial and irregular exactions are resorted to for supplying the wants of the sultan. Plunder becomes the business of every governor of a province, and thus the Koran, instead of defending Moslems from tax-gatherers, gives them up to public robbers. 'No man is secure in his property for an instant; all are compelled carefully to conceal their possessions, lest they should lose their liberty or possibly their lives and their property too. Industry is thus not merely cramped, but almost prevented or extirpated, by men being deprived of all confidence in their enjoyment of its rewards. The country, fertile in its resources of all kinds, is left waste, or only cultivated as far as the absolute necessities of providing sustenance may require. The nearer you approach the seat of government, this is more the case; and the neighbourhood of the capital, which in other countries is naturally the scene of extended labour, thick population, and great cultivation, is in Turkey marked by barrenness and neglect. Constantinople can only be approached on the land side by travelling through extensive wastes without either man or beast or tillage.' (*Political Philosophy*, ch. 3.)

In Persia the same uncertain and oppressive mode of exacting money for the use of the sovereign is resorted to and is followed by similar results.

Under the more constitutional governments of Europe, the people do not indeed suffer from violent exactions, but industry, production, and commerce are too often restrained by irregular and ill-defined taxes. Spain unhappily affords many examples of misgovernment, and the injurious character of its taxation is shown in reference to this as well as other principles. To select one instance of uncertainty: 'Every landowner is liable to have his property taken in execution for government taxes, if he is not prepared to pay a half-year or more in advance, according to the difficulties of the Exchequer; consequently he is often compelled to make great sacrifices in order to meet such exigencies.' (*Madrid in* 1835, vol. ii., p. 107.)

Perhaps there is no better example of the evils of uncertainty than that of the Stade duties levied by the king of Hanover upon all ships passing up the Elbe from the sea, and upon their cargoes. The tariff taxes 2368 articles of commerce, and lays several duties upon the same articles, so that the whole number of duties is 6688. 'There are 35 different duties upon iron; 32 duties upon yarn or twist; 18 duties upon sugar; 42 upon leather; 36 upon oil; 126 upon wood, and so on with respect to other important articles of trade.' The tariff also 'resorts to all modes and devices of taxation, by weight, by measure, by number, by value; and what is worse, it vests in the customhouse officers the sole discretion of determining by what standard they will charge the duty. The collector imposes that kind of duty which will produce the most money in the particular case. The consequence of this to the merchant is most serious. He cannot calculate or inform himself beforehand how much his goods will have to pay at Brunshausen.' (*Edinburgh Review*, No. cl., p. 361; Hutt's *Stade Duties*.) There are also arbitrary fines for trivial informalities in the ship's papers, and which are said to rest practically with the subordinate officers, who

likewise harass the merchants with a multitude of petty exactions for their own advantage. Such a system, it need scarcely be said, is most discouraging and injurious to commerce. British merchants have been loud in their complaints, and the governments of this country and of Hanover have recently engaged in negociations, which, it may be hoped, will settle these obnoxious duties upon more sound and equitable principles.

To levy a tax 'at the time and in the manner most likely to be convenient for the contributor to pay it' is always a wise policy on the part of the state. The time or manner of payment may often be more vexatious than the amount of the tax itself, and thus have the evil effects of high taxation, while it produces no revenue to the state. Suppose, for example, that a merchant imports goods and is required to pay a duty upon them immediately and before he has found a market for them:—he must either advance the money himself or borrow it from others, and in either case he will be obliged to charge the purchaser of the goods with the interest; or he must sell the goods at once, not on account of any commercial occasion for the sale, but in order to avoid prepayment of the tax. If he pays the tax and holds the goods the consumer will have to repay not only the tax but the interest; and if he parts with them at a loss or inconvenience, trade is injured, and the general wealth and consequent productiveness of taxation proportionately diminished. To prevent these evils the *bonding* or *warehousing* system was established, which affords the most liberal convenience to the merchant and a general facility to the trade of a country. Certain warehouses are appointed under the charge of officers of the customs, in which goods may be deposited without being chargeable with duty until they are cleared for consumption, and thus the tax is only paid just when the article is wanted, and when it is least inconvenient to pay it. [Warehousing System.]

Similar accommodation is granted on their own premises to the manufacturers of articles liable to excise duties. At present the customs bonding-warehouses are confined to the ports. An extension of them to inland towns would be sound in principle, very convenient to trade, and unattended by any serious risk to the revenue or difficulty of management and supervision.

The evils resulting from inconvenient modes of assessing and collecting taxes have been very seriously felt in this country under the operation of the excise laws. When any manufacture is subject to excise duties, the officers of the revenue have cognizance of every part of the process, inspect and control the premises and machinery of the manufacturer, and often even prescribe the mode of conducting and the times of commencing and completing each process; while the observance of numberless minute regulations is enforced by severe penalties. The manufacturer is put to great inconvenience and expense, and his ingenuity and resources are constantly interfered with in such a manner as to impede inventions and improvement, and to diminish his profits. Some manufactures have been entirely destroyed by oppressive regulations. The making of lenses of telescopes was at one time a flourishing trade. England had the supply of the whole of Europe, but within the last few years the manufacture has been transferred to France and Italy, entirely in consequence of the prohibition of the excise laws against conducting the necessary series of preliminary experiments. (*Digest of Reports of Commissioners of Excise Inquiry*, p. 13.) Trades less unfortunate than that just referred to are nevertheless very severe sufferers. A London distiller stated to the Commissioners of Excise Inquiry, that assuming that the duties on spirits distilled by him should be fully secured to the revenue, 'it would be well worth his while to pay 3000*l.* a year for the privilege of exemption from excise interference.' (*Ibid.*, p. 15.)

Any injury done to trade is injurious to the state by diminishing the national wealth and the employment of labour. It has the same effect also upon the revenue as excessive taxation. The high price of the article limits the consumption and consequently the revenue arising from it. The injurious effects of the excise restrictions 'must be felt in an accumulated degree by the public who are the consumers, against whom the tax operates by the addition made to the price of the commodity, not only by its direct amount, but by the necessity of compensating the manufacturer for his advance of capital in defraying it, and also by the increased cost of production.' (*Ibid.*, p. 15.) In the case of a heavy tax, which also diminishes consumption, the state, at least, derives some benefit: but in the case of onerous restrictions and impediments to trade caused by the mode of collecting a tax, the state gains nothing whatever, and the manufacturer and the consumer are seriously injured, without an equivalent to any party. If the consumer must suffer, it should, at least, be for the benefit of the revenue, for then his contributions may be diminished in some other direction. Great attention has been paid, of late years, to the improvement of the excise regulations, especially by the Commissioners of Inquiry, under the able direction of Sir Henry Parnell. Various restrictions have been removed, and it is to be hoped that the excise revenue may be found capable of being collected without inflicting greater injuries upon trade than other branches of taxation.

The net produce of a tax is all that the state is interested in, and therefore any violation of the fourth maxim of Adam Smith is liable to the same objections as those already stated in reference to the third. Such violation increases the amount of the tax directly, as the former was shown to increase it indirectly, without any advantage to the state. Facility of collection is a great recommendation to any tax, and, on the contrary, a disproportion between the cost of collecting and the amount ultimately secured is a good ground for removing a tax, though founded, in other respects, upon just principles. On this account alone, as well as for the general convenience of trade, it is worthy of serious attention, whether the customs duties upon a great number of articles of import should not be altogether repealed. Although great alterations have recently been made in our tariff, the number of articles remains the same. In 1839 there were 349 distinct articles, each producing less than 100*l.* a year, and in the aggregate only 8050*l.* There are also 132 articles producing from 100*l.* to 500*l.* each, and altogether 31,629*l.*, while 46 articles produced 98¾ per cent. of the whole customs revenue. (*Import Duties Report*, 1840, p. 4.) It is obvious that the examination of every description of merchandize and package, and the assessment of nearly 1200 different rates of duty, must greatly increase the establishment required for collecting this branch of the revenue. The cost of collecting the duties upon the larger and more productive articles of import could bear but a small proportion to the amount of the tax.

The following table may be interesting as showing the rate at which the whole revenue is collected in the United Kingdom:—

Table showing the Cost of Collecting the Revenue of the United Kingdom of Great Britain and Ireland for Ten Years, from 1832 *to* 1841 *inclusive* (compiled from the Annual Finance Accounts).

	Gross Receipt of Revenue.			Charges of Collection.			Rate per cent. for which the gross receipt was collected.		
	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*
1832	49,571,459	17	8	3,064,702	13	11	6	3	7¾
1833	52,571,116	14	11	3,560,693	4	4	6	15	5½
1834	52,753,246	17	11	3,582,635	4	4	6	15	9¼
1835	52,589,992	4	6	3,560,238	18	11	6	15	4¾
1836	54,973,677	0	6	3,493,641	17	1	6	7	1¾
1837	52,287,737	14	0	3,430,679	6	5	6	11	2
1838	52,979,236	13	10	3,450,940	12	4	6	10	3
1839	53,345,498	14	7	3,483,533	4	9	6	10	7
1840	52,916,049	8	3	3,549,009	15	5	6	14	1¼
1841	53,596,250	14	4	3,582,639	7	11	6	13	8¼

There is little variation from year to year on the gross charges of collection, but there is a considerable disproportion in the cost of collecting different branches of the revenue. In 1841 the excise cost 6*l.* 7*s.* 8*d.* per cent. in the collection; the assessed taxes 4*l.* 2*s.* 9*d.*; and the revenue arising from stamps only 2*l.* 3*s.* 4*d.*

The French revenue is collected at a much greater cost. For some years past the average revenue of that country has been 1,020,000,000 francs, or 40,000,000*l.*, and the expenses of managing and collecting that sum have amounted to 150,000,000 francs, or 6,000,000*l.*, being no less than 15 per cent. (*Commercial Tariffs, Part IV., France*, 1842, p. 11.) It is very probable that many items may be included in

the French calculation of the expenses of collection which are not stated in the English accounts; but making liberal allowance on that account, a great disproportion remains between the cost of collecting the revenue in the two countries. It may perhaps be fairly estimated that the revenue of France costs twice as much in the collection as that of England. The expenses of collecting a revenue may be high without any reference to the mode of taxation. An excellent tax may be collected in a bad manner, either by having numerous idle and highly paid officers, or by cumbrous regulations and checks, which may cost the government much and protect the revenue very little. Of these two causes of expense it is difficult to pronounce which is most injurious to a country. The former will generally be found to form part of a general system of ill-regulated expenditure: the latter may arise from unwise precautions for the security of the revenue. In France the prodigious number of official persons is notorious, and in that fact we must seek for the main cause of the enormous cost of collecting the revenue.

Different Classes of Taxes.

In selecting one or more classes of taxes for raising the revenue of a state, the principles already discussed should be adhered to as far as possible; but these do not point out any particular mode of taxation as preferable to others. Whatever mode of raising the necessary funds may be found to press most equally upon different members of the community, to be least liable to objections of uncertainty, or inconvenience in the mode or times of payment, or to be attended with the least expense, is fairly open to the choice of a statesman; unless objections of some other nature can be proved to outweigh these recommendations.

The two great divisions under which most taxes may be classed are *direct* and *indirect*.

I. *Direct Taxes.*

All taxes ought to be paid from the income of the community. To derive revenue from capital is to act the part of a spendthrift; and such a practice, as in private life, must be condemned. If the taxes of any country should become so disproportioned to its income, that in order to pay them continual inroads must be made upon its capital, its resources would fail, employment of labour would decrease, and the revenue must necessarily be reduced by the general impoverishment of the tax-payers. Such a system could not long continue as regards all capital, but it may affect particular branches of capital, or all capital in certain conditions. In whatever degree it is permitted to operate it is injurious. A tax upon legacies is avowedly a direct deduction from capital; and on that account objectionable, although it is profitable to the treasury and very easily collected. In this country legacies left to strangers are charged with a stamp duty of 10 per cent., and even when left to relatives the scale of duties is sufficiently high to cause a serious diminution of the capital. A further duty is charged on proving a will, called *probate-duty*, which is perhaps more frequently paid out of capital than income. The same observations will, of course, apply to duties charged upon succession to the personal property of intestates.

With these exceptions it has been the object of the British legislature to derive all taxes from income, either by direct assessment or by means of the voluntary expenditure of the people upon taxed commodities.

Direct taxes upon the land have been universally resorted to by all nations. Such taxes are obvious, and require but little refinement to devise; and in countries without commerce, land is the only source from which a revenue can be derived. In most of the Eastern monarchies the greater part of the revenue has usually been raised by heavy taxes upon the soil. The tangible nature of land and of its produce offers great temptations to immoderate taxation. In Spain, at the present time, the taxes upon the soil are most oppressive and injurious. 'The tax imposed on corn-fields is so heavy, that farmers in general find it more to their interest not to till their lands at all, than to run the risk of losing their costs and charges, and their labour to boot, by the exorbitancy of the intendiente's demand which they would have to meet. They have adopted the plan therefore of sowing no more wheat than is necessary for the sustenance of their own families. It is quite clear indeed to all who are conversant with the state of agriculture in Spain, that unless a complete change takes place in the system of taxation, so as greatly to reduce the burthens upon the land, there will not only be a stagnation in rural industry, but eventually the country will cease to produce a sufficient quantity for its own consumption of that superior wheat on which Spaniards pride themselves, and which was formerly and might still be grown in sufficient quantities to supply all the markets in Europe.' (*Madrid in* 1835, vol. ii., p. 109.)

The land-tax in England is one of considerable antiquity. We find that under the Saxon kings a tax of this description was in use. When the invasions of the Danes became frequent, it was customary to purchase their forbearance by large sums of money; and as the ordinary revenues of the crown were not sufficient, a tax was imposed on every hide of land in the kingdom. This tax seems to have been first imposed A.D. 991, and was called Danegeld, or Danish tax or tribute. (*Saxon Chronicle*, by Ingram, p. 168.) It was originally one shilling for each hide of land, but afterwards rose so high as seven: it then fell to four shillings, at which rate it remained till it was abolished about seventy years after the Norman conquest. (Henry, *Hist.*, vol. iii., p. 368.) A revenue still continued to be derived under different names from assessments upon all persons holding lands, which however became merged in the general subsidies introduced in the reigns of Richard II. and Henry IV. During the troubles in the reign of Charles I. and the Commonwealth, the practice of laying weekly and monthly assessments of specific sums upon the several counties was resorted to, and was found so profitable, that after the Restoration the antient mode of granting subsidies was renewed on two occasions only. (*Report of House of Commons on Land Tax as affecting Catholics*, 1828.) In 1692 a new valuation of estates was made, and certain payments were apportioned to each county and hundred or other division. These payments have varied in amount from 1*s.* in the pound to 4*s.* on the assessed annual value, according to the annual Land Tax Acts, but whatever may have been the variations in the rate levied, the valuation has been the same; and the proportion chargeable to each district has continued the same as it was in the time of king William III., as regulated by the Act of 1692. That assessment is said not to have been accurate even at that time, and of course improved cultivation and the application of capital during the last 140 years have completely changed the relative value of different portions of the soil. On account of the generally increased productiveness of land, the tax bears upon the whole but a trifling proportion to the rent, yet its inequality is very great. For instance, in Bedfordshire it amounts to 2*s.* 1*d.* in the pound; in Surrey, to 1*s.* 1*d.*; in Durham, to 3¼*d.*; in Lancashire, to 2*d.*; and in Scotland, to 2¼*d.* (*Appendix to Third Report on Agricultural Distress*, 1836, p. 545.) Adam Smith imagined that this tax was borne entirely by the landlords, but this opinion has been proved to be erroneous by modern political economists, who hold that the tax increases the price of the produce of the land, and is therefore paid by the consumers. Of that we entertain no doubt; but we are unable to agree with Mr. Ricardo, that the English land-tax is not objectionable as regards Adam Smith's first principle, viz. on the ground of inequality. (*Political Economy*, chap. xii.) He assumes that inferior land would not be cultivated until the price of produce had become so high as to remunerate the grower after payment of the tax; and that the owners of the soil therefore would not suffer, but only the consumer. But land is often cultivated for pleasure, for scientific experiment, and for speculative purposes, while in this country the exclusion of foreign supply at a time when population was rapidly increasing has forced inferior soils into cultivation. Then admitting that the consumer pays the tax, the owners of land appear to us to be in the same relation to each other as merchants would be who should be charged unequal rates of duty upon articles in which they deal. In that case the consumer would ultimately pay the tax, but no one will deny that the seller who pays the highest tax in the first instance meets his competitor at a disadvantage in the market. He must wait for very high prices, or must sell at lower profits. Such is actually the case where articles imported from different countries bear unequal rates of duty; and such, we apprehend, must be the case where the land is unequally assessed according to its value. [Land-Tax.]

A tax upon the gross rent of land would fall upon the landlord, and would be in fact a tax upon his annual income, and as such would fall with undue severity upon him, unless other classes of the community should be liable to a proportionate deduction from their respective incomes for the benefit of the state. This brings us to consider the expediency of a general tax upon all incomes.

As the object of taxation should be to obtain from each individual in a state a contribution to the expenses of government in proportion to his means; and as, in whatever form the tax may be levied, the contribution should be paid in every case from income, and not from capital, the simplest and most equitable mode of taxation would appear to be that which, after assessing the annual income of each person arising from all sources, should take from him, directly, a certain proportion of his income as his share of the general contribution. Such a tax, equitably levied, would appear to agree in theory with all the four maxims of Adam Smith; but practically, every tax upon income must abound in inequalities, in uncertainty, and in great personal hardships and inconvenience.

In order to make such a tax fall equally upon all, in the first place, the assessment must be equal. But how is this to be effected? By the voluntary statement of each person, or by investigation and proof? If by the former means, the equality of the tax would depend upon the honesty of parties placed under a temptation to be dishonest: the least scrupulous part of the community would be taxed lightly, and the conscientious would bear the main burthen of the tax. If by the latter means, viz., by investigation and proof, the dishonest still have an advantage over the conscientious: because income arising from some sources, being capable of direct assessment, cannot be concealed; while other descriptions of income are often known only to the possessor, upon whose declaration alone, in such cases, reliance must be placed.

But supposing that either by declaration or by proof, or by both combined, the actual income of each individual could be ascertained, the mere income of persons is a most fallacious test of their means or ability to bear taxation. One man has a fee-simple estate in land, or money in the funds, producing an income of 1000*l*. a year, which will descend to his children after his death; another, by a laborious and uncertain profession, also obtains an annual income of 1000*l*., dependent not only upon his life, but upon his health and a thousand accidents. The annual incomes of these two men are the same, but their circumstances are most dissimilar. Before the latter could be placed in the same position as the former, he must have an income large enough to enable him to insure his life for a sum of which the interest would be 1000*l*. a year, and still have 1000*l*. left to spend annually, after the payment of the premium. But even then, if he should lose his health, his present income would fail him, he would not be able to continue the insurance, and his position therefore would still be more precarious than that of the proprietor of land or funded property. Yet these two men, with means so unequal, would be assessed alike, and charged with equal contributions. But suppose that, instead of insuring his life, the professional man should save half his income every year, he would still be charged upon the whole, and thus his *capital* as well as his income would be taxed.

The case of annuitants also may be instanced as one, amongst numerous others, of peculiar inequality. One person invests his money in permanent securities, and retains his capital, but derives a small income, and therefore contributes a proportionally small rate of tax: another purchases an annuity, and parts with his capital; but as his income is much larger than that of the capitalist, he pays a higher tax. At first sight this may appear a just arrangement; but in fact not only the income of the annuitant is taxed, but also his capital; for that which is taxed as his income is derived partly from the interest of his purchase-money, and partly from an annual repayment of a portion of his principal.

These and many other evident cases of inequality can scarcely be questioned; but it is alleged that other taxes press with as much inequality upon different classes of persons, and that no attempts are made to equalize their pressure, as the causes exist in the circumstances of the people, and not in the nature of the taxes. (Pitt's *Speeches*, vol. iii., p. 9.) It is said that the assessed taxes affect the professional man to the same extent as the man of property. There is however this essential difference between taxes upon income and taxes upon expenditure: the former are compulsory, the latter are voluntary, and paid or avoided at the option of each individual. If a man be saving money, an income-tax seizes upon his accruing capital: a tax upon expenditure is levied upon that portion of his income only which he thinks it prudent to spend.

To smooth in some degree the inequalities of an income-tax, 1st, the annual premiums on policies of insurance should not be reckoned as income in the assessment, being clearly capital, and the payments being no longer optional, as the insurance could not be discontinued without loss; this provision was made by Mr. Pitt in 1798: 2ndly, incomes arising from realized property should be taxed at a higher rate than the profits of trades and professions: 3rdly, annuitants should be rated on such terms as to avoid the assessment of any portion of their capital as part of their income: 4thly, all persons should be liable to the tax, whatever may be the amount of their incomes.

In addition to the unequal pressure of an income-tax, which cannot be altogether corrected by any expedients, there is much uncertainty in the assessment of certain classes of persons. The vicissitudes of trade, bad debts, or deferred payments, render the incomes of commercial and professional men very uncertain; and nominal income therefore, which afterwards cannot be realized, may be charged with the tax.

But the last and strongest of the objections to an income-tax is the inquisitorial nature of the investigation into the affairs of all men, which is necessary to secure a statement of their incomes. This objection indeed is treated lightly by some; but by the mass of the contributors it is considered, beyond all question, as the most inconvenient and unseasonable quality of an income-tax. Even if the exposure of a man's affairs could do him no possible injury, yet as an offence to his feelings, or even caprice, it is a hardship which is not involved in the payment of other taxes. How many persons are anxious to conceal the amount of their wealth? It may be foolish; but they certainly must have strong motives for concealing that which most others are proud of displaying. Then who cannot sympathise with the feelings of an honest man who conceals the extent of his poverty, and, by self-denial and hard economy, is still enabled to bear up against adversity? It is in vain to deny, what all men feel, that the appearance of poverty does degrade a man in the eyes of others; and the feelings of good men ought to be respected. But apart from matters of feeling, injury of a real character is also inflicted upon individuals by an exposure of their means and sources of income. Mercantile men, from the dread of competition, take pains to conceal from others, especially if in the same business, the application of their capital, the rate of profit realized, their connections, and their credit, all of which must be disclosed, perhaps to their serious injury, when there is an investigation of their profits.

For these reasons, the mode of collecting the income tax certainly cannot be approved of as being 'most likely to be convenient to the contributor.' Its general unpopularity when in operation is the best proof of its hardship and inconvenience. Upon the whole, a tax upon income is so difficult to adjust equitably to the means of individuals, and the mode of collection is necessarily liable to such strong objection, that, if resorted to at all, it should be reserved for extraordinary occasions of state necessity or danger, when ordinary sources of revenue cannot safely be relied on.

The English assessed taxes have as few objections in principle as most modes of direct taxation. With an equitable assessment and special exemptions in certain cases, they are capable of being made to bear a tolerably just proportion to the incomes of the individuals paying them. They share, however, in the general unpopularity of all direct taxes, and it cannot be denied that they often press unequally upon particular persons. The number of windows in a house is a very imperfect criterion of its annual value, and in our opinion the house-tax which has been removed was far preferable, in principle, to the window-duty, which is still retained. The inequalities in the assessments were undeniable; but these might have been corrected by careful valuation. Under ordinary circumstances, a tax upon houses will fall upon the occupier,

who is intended to pay it; but if a very heavy tax were imposed, it would discourage the occupation of houses, lessen the demand for them, and thereby diminish the rent of the landlord, or, in other words, transfer the actual payment to him. (Adam Smith, book 5, chap ii.; Ricardo's *Political Economy*, chap. xiv.) Such a tax would be attended with very bad consequences; it would compel many persons to live in inferior houses or in lodgings, and thus diminish their comforts and deteriorate their habits of life; and by reducing the demand for houses it would limit the employment of capital and labour in building. The direct taxes upon horses, carriages, hair-powder, armorial bearings &c., being paid voluntarily by the rich to gratify their own taste for luxury or display, are not likely to meet with many objectors. The use of such articles generally indicates the scale of income enjoyed by the contributor, and the tax is too light to discourage expenditure or to make any sensible deduction from his means.

A very fair principle of levying a direct tax is exhibited by the assessment of property in every parish in England and Wales to the poor rates. Local knowledge renders a perfectly correct valuation possible, and every person owning or occupying land, houses, or other property within the parish, is assessed so much in the pound upon the annual value thereof, to raise the necessary funds for the support of the poor.

The various modes of direct taxation are too numerous to enter upon, especially as many of them involve the discussion of principles of political economy which would carry us far beyond our limits. For arguments and illustrations concerning the incidence of tithes, of taxes upon profits, upon wages, and other descriptions of direct imposts, we refer to the able works of Adam Smith, Ricardo, M'Culloch, and other eminent writers upon political economy.

II. *Indirect Taxes.*

In preferring one tax to another, a statesman may be influenced by political considerations as well as by strict views of financial expediency, and nothing is more likely to determine his choice than the probability of a cheerful acquiescence on the part of the people. All taxes are disliked, and the more directly and distinctly they are required to be paid, the more hateful they become. On this, as well as on other grounds, 'indirect taxes,' or taxes upon the consumption of various articles of merchandize, have been in high favour with most governments. 'Taxes upon merchandize,' says Montesquieu, 'are felt the least by the people, because no formal demand is made upon them. They can be so wisely contrived, that the people shall scarcely know that they pay them. For this end it is of great consequence that the seller shall pay the tax. He knows well that he does not pay it for himself; and the buyer, who pays it in the end, confounds it with the price.' (*Esprit des Lois*, livre xiii., chap. vii.) This effect of indirect taxes is apt to be undervalued by writers on political economy; but it is undoubtedly a great merit in any system of taxation (which is but a part of general government) that it should be popular and not give rise to jarring and discontent. A tax that is positively injurious to the very parties who pay it without thought, is, certainly not to be defended merely on the ground that no complaints are made of it; but it may be safely admitted as a principle, that of two taxes equally good in other respects, that is the best which is most acceptable to the people. The very facility, however, with which indirect taxes may be levied, makes it necessary to consider the incidents and effects of them with peculiar caution. The statesman has no warning, as in the case of direct taxes, that evils are caused by an impost which is productive and which every one seems willing to pay. When any branch of industry is visibly declining, and its failure can be traced to no other cause than the discouraging pressure of a tax, the necessity of relief is felt at once; but if trade and manufactures are flourishing, and the country advancing in prosperity, it is difficult to detect the latent influence of taxes in restraining that progress, which but for them would have been greater; and still more difficult to imagine the new sources of wealth which might have been laid open if such taxes had not existed, or had been less heavy, or had been collected at different times or in different ways.

The government is directly interested in the increase of national wealth, and taxes upon commodities should be allowed to interfere with it as little as possible. On this account duties upon raw materials are very objectionable. They increase the price of such materials, and thus limit the power of the manufacturer to purchase them, and to employ labour in increasing their value, and in adding to the production and capital of the country. They discourage foreign commerce and the employment of shipping; for as the power of buying is restrained, so also is that of selling, and the interchange of merchandize between different countries is checked. Moreover, by increasing the price of the exported manufactures, they limit the demand for them abroad and subject them to dangerous competition.

Similar objections may be urged against taxes upon domestic manufactures, since by increasing the price they diminish consumption, and consequently discourage the manufactures, which if left to themselves would have given employment to more capital and labour, and would have added greatly to the amount of national wealth and prosperity. The object of a government should always be to collect its revenue from the results of the successful employment of capital and industry, and not to press upon any intermediate stage of production.

Adopting this view of the objects of taxation, the British legislature has of late years very wisely repealed or reduced various duties upon raw materials and upon manufactures. Of the former we may instance the customs' duties on barilla; on raw, waste, or thrown silk; on cotton-wool and sheep's wool, unwrought-iron, hemp, and flax; which have been from time to time very much reduced. Of the latter, the taxes on printed goods, on candles, and on tiles, have been altogether removed; and those on plate and flint glass, on malt, and on soap, have been partially remitted. There are still many similar taxes which need revision. Of these perhaps the most injurious are the heavy duties upon foreign timber, which we shall show other reasons for condemning, in treating of protective duties; but in this place they must be particularly censured, as offering a serious obstruction to ship-building (one of the most important branches of national industry in a maritime country), and to the construction of buildings for the convenience of trade and manufactures. The amended tariff of 1842, which for many reasons is a most important change in the financial policy of this country, has reduced the duty on colonial timber to a rate perhaps unnecessarily low; that on foreign timber, though much reduced, is still too high.

One of the chief recommendations of indirect taxes is, that, when placed upon the proper description of articles, the payment of them by the consumer is optional. If charged upon what may be strictly called the necessaries of life, their payment becomes compulsory, and falls with unequal weight upon labour. Competition generally reduces a large proportion of the working classes to a state which allows them but little if anything beyond necessaries; consequently a duty upon these, as it will have no effect in diminishing the competition of labour and in raising wages, must reduce the comforts and stint the subsistence of labouring men.

That class of articles commonly called luxuries, of which the consumption is optional, is a very fair subject of taxation. In principle there is no objection to such taxes: they do not interfere with industry or production, but are paid out of the incomes of the contributors, and paid willingly, and for the most part without undue pressure upon their means. But in laying on taxes upon particular articles of this description care must be taken to proportion the charge to the value of the article. Excessive duties fail in the very object they have in view, by rendering the revenue less productive than moderate duties; while the causes of their failure are injurious to the wealth of the country by discouraging consumption, and to its morals by offering an inducement to smuggling. It is only by experience that the precise point can be found at which the revenue is most productive, consistently with an unchecked consumption and an absence of smuggling; but it may be assumed as certain that whenever a tax adds very greatly to the price of an article of general consumption, it puts it out of the reach of many who are anxious to purchase it, and tempts smugglers, by the chance of a large profit, to evade the payment of the duty. On the contrary, when a duty is moderate, it adds so little

to the price of an article, that it will scarcely affect its consumption; and the profit arising from evasion of the duty is so small as not to cover the risk and penalties of detection. In proof of these facts there has been ample experience in the taxation of this country, and a few instances may serve as instructive illustrations.

In 1823 the excise duties upon Scotch and Irish spirits were reduced from 5*s.* 6*d.* to 2*s.* per gallon, and the immediate effect produced upon the apparent consumption and upon the revenue will appear by the following statement for the two years preceding and following the reduction.

Quantities of spirits made in Ireland and Scotland which paid duty for home consumption, stating the rate of duty paid, and the net revenue:—

IRELAND.

	Gallons.	Rate of Duty.	Net Revenue.
1821	2,649,170	5*s.* 6*d.* per Irish gallon	£912,288
1822	2,328,397		797,518
1823	3,348,505	2*s.* per English Wine Gallon from 10th October	634,460
1824	6,690,315	Ditto	771,690
1825	9,262,744	Ditto	1,084,191

SCOTLAND.

	Gallons.	Rate of Duty.	Net Revenue.
1821	2,229,435	5*s.* 6*d.* per English Wine Gallon	£727,650
1822	2,079,556	Ditto	691,136
1823	2,232,728	2*s.* from 10th October	536,654
1824	4,350,301	Ditto	520,624
1825	5,981,550	Ditto	682,848

In 1826 6*d.* was added to the duty, and again in 1830 a similar addition was made, the effect of which is shown by a continuation of the statement:—

IRELAND.

	Gallons.	Rate of Duty.	Net Revenue.
1826	6,837,408	2*s.* 10*d.* per Imperial gallon	£964,509
1827	8,260,919		1,122,096
1828	9,937,903		1,395,721
1829	9,212,223		1,305,064
1830	9,004,530	2*s.* 10*d.*, 3*s.*, & 3*s.* 4*d.*	1,409,128
1831	8,710,672	3*s.* 4*d.*	1,451,580
1832	8,657,756	Ditto	1,442,845
1833	8,168,596	Ditto	1,360,769

SCOTLAND.

	Gallons.	Rate of Duty.	Net Revenue.
1826	3,988,788	2*s.* 10*d.* per Imperial gallon	£563,263
1827	4,752,199	Ditto	672,441
1828	5,716,180	Ditto	809,559
1829	5,777,280	Ditto	818,448
1830	6,007,631	2*s.* 10*d.*, 3*s.*, & 3*s.* 4*d.*	939,258
1831	5,700,689	3*s.* 4*d.*	950,041
1832	5,407,097	Ditto	901,182
1833	5,988,556	Ditto	998,031

These tables show the effects of taxation in encouraging or repressing smuggling, rather than its influence upon consumption. Taking the case of Ireland, it would be impossible to believe that the actual drinking of spirits could have been increased more than threefold in a few years, even if there had been no evidence of illicit distillation; but before the reduction of duty in 1823, an enormous amount of smuggling had been detected, and there were other means of estimating the extent of frauds practised upon the revenue. For instance, in 1811, the duty had been only 2*s.* 6*d.* a gallon, and in that year no less than 6,500,361 gallons had paid duty; while, in 1822, when the duty was 5*s.* 6*d.*, only 2,328,397 gallons were brought to charge. The revenue commissioners, on whose recommendation the duty was reduced in 1823, then estimated the annual consumption of spirits in Ireland at ten millions of gallons, and the illicit supply at about seven millions. (*Fifth Report of Revenue Commissioners*, pp. 8, 19.)

In 1827 the duties on spirits made in England were reduced from 12*s.* 6*d.* to 7*s.* a gallon. The average consumption for three years to 1827 was 3,677,457 gallons, and the revenue 2,281,526*l.* In 1829 (only two years after the reduction) the consumption was 7,700,766 gallons, and the revenue 2,695,268*l.*, or 413,742*l.* more than the higher duty had produced. (Parnell's *Financial Reform*, 4th ed., p. 44.)

It has been a common opinion that spirits should not be treated merely as a source of revenue; but that being injurious to the morals of the people, the consumption of them should be repressed by heavy duties. It has accordingly been the object of this and of other governments to limit the consumption of spirits, and at the same time to raise a large revenue from it. The object is unquestionably a good one if it could be secured: but the result of numerous experiments has proved that taxation should be conducted with reference to the immediate object of obtaining a revenue in the best manner; and that the interests of a country are promoted by following out just principles of taxation, rather than by seeking indirectly, and by a violation of those principles, to accomplish objects which, if attainable, can only be attained by other means. The signal failure of a measure in the last century for discouraging the drinking of spirits is a strong example of the futility of attempting to force a change in the habits of the people by a tax. In 1736 a tax of 20*s.* a gallon was imposed upon all spirits, with very heavy penalties for evasion of the duty. The tax was extremely unpopular, and was evaded to such an extent, that in two years no less than 12,000 persons were convicted of offences against the law. Indeed the measure proved altogether so odious and so impracticable, that it was abandoned after six years of vexatious and unprofitable trial.

High duties upon foreign articles imported into a country are liable to all the objections which have been stated as applying to immoderate taxes upon consumption, and they are chargeable with another,—they diminish importation, and thereby restrict commercial intercourse and the demand for and exportation of domestic produce or manufactures.

The number of gallons of brandy and geneva imported and retained for consumption, on an average of four years to 1807, was 1,820,000. The duty was then 14*s.* a gallon, and the revenue 1,370,000*l.* In 1814 the duty was made 18*s.* 10*d.*, and on an average for the four succeeding years, the number of gallons entered for home consumption was 742,000, and the revenue 825,000*l.* Thus a loss of 545,000*l.* a year was sustained by the revenue, the legitimate trade in brandy discouraged, and a rich premium offered to the smuggler. The present duty is 1*l.* 2*s.* 6*d.* a gallon, and in the year ended 5th January, 1842, only 1,180,641 gallons were entered for home consumption, the gross revenue on which was 1,347,461*l.*, or 23,000*l.* less than in 1807, notwithstanding the great increase of wealth and population since that time. That French brandy is smuggled into this country in large quantities is notorious; and when we consider that the duty is estimated at 400 or 500 per cent. on its original price abroad, the inducement to evade it is so great, that we cannot be surprised if all the vigilance of our customs establishment is rendered ineffectual. Indeed so regular and certain is the smuggling trade, that it is made the subject of insurance, like other commercial risks, and it is even said at premiums of from 10 to 15 per cent., which bear no proportion to the profits, if the speculation be successful.

The success of moderate duties upon articles of consumption, in encouraging the use of them, placing them within the reach of a larger number of persons, and at the same time augmenting the revenue, was never better shown than in the article of coffee. In 1824 the duty on British plantation coffee was 1*s.*, upon East India 1*s.* 6*d.* and upon foreign coffee 2*s.* 6*d.* per lb. In 1825 those duties were reduced one-half, and the consequence has been considerably more than a threefold increase in the consumption, while the revenue has been more than doubled. In the three years preceding the reduction, the consumption and revenue were as follows:—

	Quantities cleared for Consumption.	Net Revenue
1822	7,669,351 lbs.	£387,342
1823	8,454,920	428,613
1824	8,262,943	420,988

In the three years following the reduction, the consumption greatly increased, but not sufficiently to improve the revenue:

	Quantities cleared for Consumption.	Net Revenue.
1826 .	13,203,323 lbs.	£336,570
1827 .	15,566,376	399,960
1828 .	17,127,633	440,245

But the consumption has since been rapidly increasing, and in the last two years the consumption and revenue thus appear:—

	Quantities cleared for Consumption.	Net Revenue.
1840 .	28,708,033 lbs.	£921,550
1841 ,	28,420,980	887,721

The slight falling off in the last year may be accounted for by the general depression of trade, and perhaps in some measure also by the addition of 5 per cent. to the customs duties, which was then in operation.

In 1835 coffee, the produce of British possessions in India, was admitted at the same duty as plantation coffee, viz. 6*d*. per lb., and the effect of the reduction, in encouraging the growth of the plant in India and the consumption of the berry in this country, has already been very great, and perhaps the coffee trade of the East may as yet be considered in its infancy. In 1834, the year before the reduction, 8,875,961 lbs. were imported from the East India Company's territories and Ceylon; and in 1840, 16,885,698 lbs., or nearly double. The new customs tariff effects a further reduction of duty. That on foreign coffee is for the future to be 8*d*. a lb., and on coffee the produce of British possessions only 4*d*. An increased consumption will doubtless be the effect of this measure, and ultimately the revenue will be improved.

Thus reductions of existing duties are proved by these examples to increase the revenue; but whether the effect of them be immediate or deferred must depend upon a variety of circumstances. If the reduction puts an end to extensive smuggling, the revenue will derive immediate benefit, as both the demand and the supply of the article already exist, and the reduced tax, without affecting production or consumption, acts as a police regulation, and at once protects the revenue from fraud. But where there is little or no smuggling, and the revenue can only be increased by means of additional consumption, the effect of reduced duties may be deferred and even remote. The article may have to be produced; capital, skill, labour, and time may be required to provide it in sufficient quantities to meet the growing demands of the consumer; and even should the supply become abundant, the habits and tastes of a people cannot be changed on a sudden. The high price of an article may have placed it out of their reach, and in the meanwhile they may have become attached to a favourite substitute, or may be slow to spend their money upon a commodity which they have learned to do without. These and other causes may defer for a considerable time such an increase of consumption as would make up for the reduced rate of tax, especially when the reduction has been so great as to require an extraordinary addition to the previous amount of consumption, before the sacrifice made in the revenue can be redeemed. But where the article on which it is proposed to reduce a tax is already in universal request, and the supply immediate and abundant, and where the tax is so heavy as to restrain consumption, no present loss need be apprehended from a remission of part of the tax, and a very speedy increase of revenue may be expected. Sugar is an article of this description. It has become a necessary of life as well as a favourite luxury. There are scarcely any limits to the supply that could be raised, and the present duties add materially to the price and check consumption. As a proof of the suddenness with which the consumption of foreign sugar might be expected to increase if the excessive duty were reduced, we may refer to the effects of equalizing the duties on East and West India sugars in 1836. In that year the duty on East India sugar was reduced from 32*s*. the cwt. to 24*s*. In 1835 the quantity imported had been 137,976 cwts.; and in 1837, one year only after the change, the import had increased to 302,945 cwts.; in 1838, to 474,100 cwts.; and in 1839, to 587,142 cwts. As the tax was diminished only by one-fourth, and the consumption was immediately more than doubled, the revenue at once gained considerably by the reduction of duty.

A recent financial experiment will serve to show how little an increased revenue can be depended upon as the result of an augmentation of taxes upon articles of consumption. In 1840 an addition of 5 per cent. was made to all the duties of customs and excise, and a proportionate increase of revenue was anticipated, but not realized. The net produce of the customs and excise in the year ending January 5th, 1840, amounted to 37,911,506*l*. The estimated produce for the year ending January 5th, 1842, was 39,807,081*l*., 1,895,575*l*. being expected from the additional 5 per cent. The actual increase however was only 206,715*l*., or little more than one-half per cent., instead of the 5 per cent. which had been expected. This result was undoubtedly in part caused by a general stagnation of trade, and by the consequent distress which prevailed in that year, but we notice it because the principle of an indiscriminate augmentation of existing taxes, without reference to their present amount, character, and circumstances, is very unwise. We have said that experience alone can show the precise rate of a particular tax which will not affect consumption and will at the same time discourage smuggling. It must be presumed that existing rates have been fixed in order to secure these results, and that they are justified by experience. To add to them therefore, not because they are insufficient for their immediate object, but because a general addition to the revenue is needed, is to neglect experience and to disturb the proper relations between the amount of tax and the value of particular articles. During the last century it was a common financial course to add a general per centage of increase upon all the customs duties whenever the revenue was found to be insufficient for immediate purposes. To this unwise policy must be attributed many of the strange anomalies which up to this time have existed in the British tariff. Any recurrence to so unscientific a mode of taxation should be avoided. The tax upon each article ought to be adjusted by itself upon sound principles, and then should not be changed merely to save the trouble or to avoid the unpopularity of selecting particular articles for increased taxation or of inventing new burthens.

Protective, Discriminating, and Prohibitory Duties.

The legitimate object of taxation is that of obtaining a revenue in the least injurious manner for the benefit of the community; but this object has constantly been overlooked for the sake of ends not fairly to be accomplished by taxation. It is natural for a legislature to endeavour by every means in its power to encourage agriculture, trade, and manufactures; and it would be culpable to neglect any proper means of encouragement, which are not only beneficial to particular interests, but add to the general prosperity. Unfortunately however the zeal of most legislatures upon this point has been misdirected. They have seized upon taxation as the instrument of protection and encouragement; and, using it as such, have injured the great mass of their own countrymen, and ultimately have failed in promoting the very interests they had intended to serve. All that we can hope in this and other European countries is a gradual adoption of sound principles, and the correction, at some distant period, of the mistakes which have been acted upon for centuries; but it is to be hoped that in the new countries of the world, where systems of revenue are not yet established, or are growing up with the progress of society, none of the errors of the Old World will be suffered to have a beginning. If once the system of protection has existed, severe injuries and even injustice are inflicted whenever an attempt is made to undo the mischief which has been done. Reason and experience unite in teaching the impolicy of protective taxes; and, in our own country, it is now so generally acknowledged, that nothing but the extreme difficulty of withdrawing the protection which has been given obstructs legislation upon sound principles.

The object of a protective duty is to raise artificially the price of the produce or manufactures of one country as compared with the produce or manufactures of another. A heavy tax easily effects this object, and thus prevents competition on the part of that country whose commodities are taxed, and establishes a monopoly in the supply of those commodities in favour of the parties for whose benefit the tax was improved. The revenue, the avowed object of a tax, so far from being improved, is here actually sacrificed by the exclusion of merchandise, which at moderate duties would fill the coffers of the state. The state clearly is a loser; the foreigner, whose goods are denied a market, is a loser. Who then gains by these losses? Not the consumer; for the more abundant the supply, the better and

cheaper will he find the market; but the seller, who is enabled to obtain a high price for his wares because he has a monopoly in the sale of them, is the only party who gains. The community at large suffer doubly: first, by having to buy dear instead of cheap goods, or by being denied the use of them altogether; and secondly, by being obliged to pay other taxes which would not have been required, if the very articles which would have made their purchases cheaper had been charged with a moderate impost. Even the sellers, for whom all these sacrifices are made, do not derive the benefit which might be expected. In the goods which they sell themselves, indeed, they are gainers; but in purchasing of other monopolists they lose by an artificially high price, like the rest of the community. It constantly happens, too, that although the prices at which they sell are high, their profits are reduced, by the competition of others selling the same articles, to the general level of profits throughout the country. When this is the case, all parties, without exception, are losers—the state, the community, and the monopolists. The general injury done to trade by the protective system is too extensive a question to enter upon, but it is well illustrated in the 'Report of the Committee of the House of Commons upon Import Duties' in 1840.

Protection may be accomplished by actual prohibition of the import of particular articles, by exorbitant duties which amount to prohibition, or by such duties only as give the home producer an advantage. Duties may also discriminate between the produce of different countries, and give the preference to some, to the injury and exclusion of others.

In this country all these modes of protection have been resorted to. For the protection of agriculture, foreign cattle, sheep, swine, beef, mutton, pork, and other provisions have been entirely prohibited. High duties have been placed upon the importation of corn on a sliding-scale, so devised as to exclude it entirely, except in times of scarcity; and more moderate duties are payable upon various articles of agricultural produce. The prohibitions however have recently been removed, and moderate import duties substituted. The corn-laws, though the sliding-scale is still adhered to, have been considerably modified, and, it is hoped, will hereafter admit a larger amount of foreign grain, and enrich the revenue. The principle of a sliding-scale, we would here observe, apart from its general policy, is very injurious to the revenue. When the high part of the scale is in operation, it acts as a prohibition; and when the lower duties only are payable, they are comparatively unproductive. The loss sustained by the consumer on account of the protective duties on corn has been variously estimated at from 12,000,000*l.* to 50,000,000*l.* a year; and yet it is well known that money invested in the purchase of land produces a very low rate of interest, not exceeding 3 per cent., and that persons engaged in agriculture, for whom the protection is maintained, have been continually complaining to parliament of their distress.

Upon various articles of manufacture there have been prohibitory and highly protective duties. In 1825 the former were removed; and the latter have, in the present session of parliament (1842), been so modified as to be very fair taxes for the purposes of revenue.

Duties are called discriminating when they are not levied equally upon the produce or manufactures of different countries. The object of them is to give an advantage to the country on whose commodities the tax is lightest, as compared with others. To obtain such a preference has been the object of various negociations and commercial treaties between different states, as it opens extensive markets to the industry of the favoured nation. By the present commercial policy of England, the principle of discrimination may be said to be confined to the protection of our colonies against the competition of foreign countries. As regards each other, all foreign countries enjoy equal commercial advantages in their intercourse with England. Our colonial policy is so wide a question, involving political and commercial considerations of high importance, that we can only touch upon it. It may be contended that colonies should form an integral part of the mother country, and that the commercial intercourse between the several parts of the British empire ought to be viewed as a vast coasting-trade. If this principle were acted upon, it would certainly present a grand fiscal union worthy of admiration; but the existing system does not partake in any degree of the character of a coasting-trade. To put it upon such a footing, the duties on colonial produce imported into the United Kingdom should be little more than nominal, and we should rely upon productive imposts upon foreign produce for our revenue. Our practice is the reverse of this. Where our taxes discriminate, we derive our revenue from the colonial produce; and we either exclude foreign produce altogether, or limit its introduction so much as to prevent it from contributing materially to the revenue. The object of the duties upon the foreign produce, which would enter into competition with the colonies, is not revenue, but exclusion, for the sake of creating a monopoly in favour of the latter. This system we have already condemned, even when established for the protection of trade and agriculture in the mother country; and upon fiscal grounds it is equally indefensible when applied to the colonies, and quite as injurious to the community. There are two great articles of consumption, viz., sugar and timber, upon which the discriminating duties deserve especial notice. Sugar imported from the colonies pays a duty of 24*s.* the cwt.; from foreign countries 63*s.* The disproportion is so great, that foreign sugar is comparatively excluded from the consumption of our people, who are forced to rely upon the colonies for the supply of that important article. The population of the country has rapidly increased, and with it the demand for most articles of consumption. It is painful to see the supply of sugar so forcibly restrained by our commercial policy that the consumption has not increased for ten years. In 1831, 3,781,011 cwts. were retained for home consumption; and in 1840 only 3,594,832 cwts. So inadequate have the colonies alone been to supply our wants, that their exports have actually been diminishing. In 1831 the West Indies exported to the United Kingdom 4,103,800 cwts. In no succeeding year has their export been so great; and in 1840 it had sunk so low as 2,214,764 cwts. During this period the consumption of coffee, cocoa, and tea had considerably increased, and the people must therefore have suffered a serious privation on account of the limited supply of sugar. The community is plainly a loser by the colonial monopoly; and the falling off of the produce of the West Indies, in spite of an increasing demand for it, is not the only proof that they have not gained much by their protection: meanwhile the revenue has lost incalculable sums by the exclusion of foreign sugar, which, with moderate duties, might be imported at a low price in unlimited quantities.

The discriminating duties upon timber have been peculiarly injurious to this country, and it is extremely doubtful whether they have conferred any benefit upon the colonies. They have acted as a bounty of 45*s.* the load in favour of timber the growth of British possessions, and have obliged the consumer either to pay a tax of 225 per cent. (not for purposes of revenue, but for the protection of other interests), or to use an inferior article, less suited to his uses, and cheaper only by reason of the duty. Extensive charges are, happily, about to take effect, which will, in some measure, equalize the duties upon foreign and colonial timber. On the 10th October, 1842, the duty upon foreign timber will be reduced from 55*s.* the load, to 30*s.*, and on the 10th October, 1843, to 25*s.* The duty on colonial timber is, at the same time, to be reduced from 10*s.* to 1*s.* Eventually therefore the disproportion will be only 24*s.* the load, instead of 45*s.*

Export Duties.

We have hitherto spoken of taxes upon such commodities only as are consumed by the subjects of the state for whose benefit they are imposed, and which are either produced within the country or imported into it. Duties levied upon goods exported to foreign countries are ultimately paid by the foreign consumer, and thus have the effect of making the subject of one state bear the burthens of another. However desirable this may appear to the state, whose treasury is enriched at the expense of foreigners, the expediency of such duties will depend upon peculiar circumstances, and great nicety is required in the regulation of them. If a country possesses within itself some produce or manufacture much in request abroad, and for the production of which it has peculiar advantages, a moderate export duty may be very desirable. In this manner Russia, which has almost a monopoly in the supply of tallow to the rest of Europe, derives a consider-

able revenue from an export duty upon that article. Upon the same principle a duty upon machinery exported from Great Britain would have been politic. British machinists far excelled all others in skill and ingenuity, and foreign manufacturers were willing to pay almost any price for their machinery. Notwithstanding the prohibition, large quantities have been smuggled abroad at an enormous cost, but the difficulty and expense of evasion have been so great that foreigners have latterly almost confined their purchases, in this country, to models and drawings, and have made the machinery themselves, with the assistance of British artizans, whom they have enticed abroad by extravagant wages. (*Reports of Committees of the House of Commons on Artizans and Machinery*, in 1824 and 1825, and *On the Exportation of Machinery*, 1841.) If, instead of prohibiting the export, a duty of 7½ or 10 per cent. *ad valorem* had been imposed, foreign manufacturers would have paid much less for the machinery purchased by them in England than they could have had it made for abroad; there would have been a large export trade from this country, and a considerable revenue. The partial relaxation of the prohibitory law in 1825, by granting licences to export certain kinds of machinery, has shown the extent to which the trade might have been carried under a more liberal policy. The official value of machinery exported under licence in 1840 was 593,064*l.*, in addition to various tools allowed by law to be exported, of which no account was taken. (*Sess. Paper*, 1841, No. 201, p. 257.)

On the same grounds a moderate duty on the export of coal, being a product peculiarly abundant and of good quality in this country, is a legitimate tax, which would be paid by the foreigner, and, if sufficiently moderate, would not be injurious to the coal trade.

But while moderate export duties upon articles of which a country has almost the exclusive supply may be advisable, heavy duties will check the demand abroad in the same manner as they have been shown to affect the consumption of commodities at home. In the same manner also they are injurious to trade and unprofitable to the revenue.

All duties whatever should be avoided upon the export of produce or manufactures which may be also sent from other countries to the same markets. They would discourage trade and offer a premium to foreign competition.

Although the temptation is great to shift taxes from one country to another by means of export duties, this temptation is equally great in all countries; and if their several governments should be actuated by the desire to make foreigners contribute to their revenue, their opportunities for carrying out such a system would probably be equal, and thus retaliations might be made upon each other, which, after all, would neutralize their efforts to tax foreigners, and leave them in the same position as if they had been contented to tax none but their own subjects. In this power of retaliation lies the antidote to the evil of one state being forced to bear the burthens of another as well as its own. Every state would naturally resist such an imposition upon its subjects, and export duties can therefore only be safely resorted to in such peculiar cases as we have noticed, where foreigners are willing to pay an increased price for commodities which they must have, and which they cannot obtain so good or so cheap from any other place.

[Customs; Excise; Land Tax; Post-Office; Stamps; Taxes; Tithes: Warehousing System.]

TAXA'CEÆ, a natural order of plants belonging to the class Gymnospermæ:—This order possesses the following essential characters. The flowers are monœcious or diœcious, and are naked, or solitary surrounded by imbricated bracts, or in spikes surrounded by bracts. The male flowers have no calyx, and several stamens, mostly united at the base, with the anthers either combined or distinct. The female flowers are solitary and naked; the ovules are naked, with the foramen at the apex. The seeds are hard, and are sometimes surrounded by a succulent, coloured, cup-shaped pericarp: they possess fleshy albumen, and a straight dicotyledonous embryo. The plants of this order are trees or shrubs, having a woody tissue marked with circular disks, with evergreen and mostly narrow, rigid, entire, and veinless leaves.

This order is very characteristic of the class to which it belongs, in the absence of any regularly formed ovary, and the consequent exposed or naked state of the ovule and seeds. In this respect it offers a lower state of organization than the Coniferæ, or Pine tribe, the ovules of which have a kind of protection in the hardened scale-like bracts which constitute the cones of that order. The foliage also of Taxaceæ differs from Coniferæ, in their possessing a greater tendency to expand and form veins within their tissue. In the few species of Taxaceæ that possess veins, they are not straight and parallel, as in Endogens, but are forked and of a uniform thickness, similar to those possessed by the higher forms of Cryptogamia, as the Ferns.

This order consists of plants that are but thinly distributed on the surface of the earth. They are mostly natives of temperate parts of Europe, Asia, Africa, and America. The order yields trees which are valued for their timber, and, like Coniferæ, possess resinous properties. The branches of the *Dacrydium taxifolium* are used in New Zealand for making spruce-beer. [Taxus; Salisburia.]

TAXA'TIO ECCLESIA'STICA, signifies the assessment and levy of taxes upon the property of the church and of the clergy. The pope once claimed in all countries the first year's whole profits and the tenth part of the whole annual profits of every ecclesiastical benefice. These were called 'First-Fruits and Tenths' [First-Fruits; Tenths], and were, for the most part, paid willingly by the clergy to their ecclesiastical superior. The popes founded their claim upon scriptural precepts and practice. They referred to Abraham, a priest, paying tithes to Melchizedeck, the high priest (*Gen.*, xiv. 20; and *Hebr.*, vii. 4); and to the Levites, in the Mosaic law, paying the second tithes, that is, the tithes of their tithes, to the priest: 'Thus shall you offer an heave-offering unto the Lord of all your tithes which ye receive of the children of Israel, and ye shall give thereof the Lord's heave-offering to Aaron the priest.' (*Numb.*, xviii. 28; Fuller's *Church History*, p. 226.)

The pope had his collectors in every diocese, who sometimes by bills of exchange, but generally in specie, yearly returned the tenths and first-fruits of the clergy to Rome.

But while the clergy were thus liable to taxation by their ecclesiastical head, it was maintained by the Roman Catholic church that their property enjoyed complete immunity against all claims of temporal powers, being set apart for the service of God, the support and dignity of the Christian church, and for works of charity. Upon this point frequent contests very naturally arose, and the vast possessions of the church tempted the pope and temporal princes by various modes to exact contributions from the clergy. The means resorted to by these respective powers to raise a revenue from the clergy, and the laws and customs that prevailed upon the matter, may be conveniently stated by dividing the subject into—

1. Taxation of the church or clergy by the pope for ecclesiastical purposes.

2. By temporal princes for the service of the state.

1. The pope was by no means satisfied with the regular contributions of the clergy, but continually applied to them for extraordinary funds for special purposes. In 1199 Pope Innocent III. issued a bull commanding the prelates and clergy of the Christian church to pay the 40th part of all their revenues to defray the expenses of a crusade. This is said to have been the first attempt to impose a tax on the clergy of all nations by the authority of the pope as head of the church. To enumerate only a small portion of the instances in which the pope afterwards exacted taxes from the clergy in the various countries of Europe would occupy much space; but a few examples from English history may be collected.

In 1225 the pope entertained a project by which the revenues of two prebends in every cathedral, and the portion of two monks in every monastery, in all the countries in communion with the church of Rome, were to have been granted to the pope for the better support of his dignity. When this project was laid before the parliament of England in 1226, they evaded a direct answer to the papal legate, by alleging 'that this affair concerned all Christendom; and that they would conform to the resolutions of other Christian countries.' (Wilkin's *Concilia*, vol. i., p. 620.)

Two years afterwards the king of England, Henry III., in order to induce the pope to interfere in a dispute concerning the appointment of an archbishop to the see of Canterbury, recently vacant by the death of Cardinal Lang-

ton, promised him a tenth of the moveables not only of the clergy, but of the laity. In this proceeding there appears to have been a twofold peculiarity. First, a temporal prince offered the pope a contribution from his clergy, which commonly originated with the pope; and secondly, a tax was to be levied upon the laity not for the service of the state, but for the benefit of a foreign ecclesiastic. The strangeness of the circumstances however did not prevent the pope from taking immediate advantage of the king's offer, and he accordingly sent a legate into England to collect the tenths. His demand met with some opposition, indeed, chiefly from the barons, but the pope and the king together were too powerful to be resisted. The legate, to shorten the work of collection, obliged the bishops to pay the tax for their inferior clergy; and when any of them complained that they had no ready money, he introduced them to certain Italian usurers whom he had brought with him for that purpose, who lent them the sums demanded at an exorbitant rate of interest. (Matthew Paris, p. 362.)

In the same reign the pope's legates were constantly demanding presents from the bishops, monasteries, and clergy, and convening assemblies of the church with no other object than to extort money. Their proceedings created such disgust that the great barons sent orders to the wardens of the seaports to stop all persons bringing any bulls or mandates from Rome, and at last succeeded in driving the legate himself out of the kingdom. (Matthew Paris, p. 659.) Little good however was effected by these measures, for we find that in 1246 the pope demanded the half of all the goods of the non-resident clergy and the third of those who resided. (Ibid., 708.) The resistance met with in this case deterred the pope from enforcing his demand; but the sums which he continued to draw from the clergy at that time appear to have been enormous, and the histories of that period are full of complaints and remonstrances against papal exactions. An act was passed by the parliament in 1307 (*Statute of Carlisle*, 35 Edward I.), to restrain, in some measure, the exactions of the see of Rome, but apparently with little good results; for seventy years afterwards we find the Commons in parliament still protesting against the extortions of the pope. In their remonstrance to the king upon that grievance they asserted, 'that the taxes paid to the pope yearly, out of England, amounted to five times as much as the taxes paid to the king.' (Cotton's *Abridgment*, p. 128.)

Although complaints continued long after this period, no measures were effectual in limiting the demands of the court of Rome until the pope's authority was altogether suppressed in England at the Reformation in the reign of Henry VIII.

2. The immunities claimed by the church were not effectual in protecting its revenues from being laid under contribution for the service of the state. The kings of England, sometimes by the pope's authority, sometimes by forced or voluntary compliance on the part of the church, and sometimes by their own direct power, obtained large sums from the clergy.

William the Conqueror found the church very wealthy, and subjected it to much spoliation. (Matthew Paris, p. 5.) A singular occasion for taxing the clergy arose in the reign of Henry I., A.D. 1129. An ecclesiastical council, assembled at London, denounced all married clergymen, and decreed that they should put away their wives. The council committed to the king the execution of their decrees, but he, instead of compelling the clergy to send away their wives, imposed a tax on those who chose to retain them, which is said to have been very productive.

The pope was not unwilling to assist in oppressing the clergy for the benefit of kings, when they were inclined to further his own objects, either by undertaking crusades, carrying on wars against his enemies, or making concessions to him. He could not suffer the immunities of the church to be infringed by the temporal power, but often placed at the disposal of princes the revenues of the church by his own authority. Thus the pope, by virtue of his apostolical power, granted King Henry III., by several bulls, the goods of all clergymen who died intestate, the revenues of all vacant benefices, and of all non-residents. In 1253 Pope Innocent XXII. gave the first-fruits and tenths of all ecclesiastical benefices to the king for three years. This grant made a valuation or taxation of the benefices necessary, which was accordingly undertaken in the following year, and is sometimes called the 'Norwich Taxation,' and sometimes 'Pope Innocent's Valor.' The same prince, with the pope's concurrence, extorted large sums from the clergy in 1255 to carry on his wars with Sicily. Bills amounting on the whole to 150,540 marks were drawn upon all the bishops, abbots, and principal clergymen of the kingdom by Walleran, bishop of Hereford, who resided at Rome as an agent for the church of England: these bills were made over to Italian merchants, who, it was pretended, had already advanced the money for the Sicilian war. All resistance on the part of the church to these unjust demands of their own spiritual superior was unavailing, and after much remonstrance and opposition the money was paid. (Matthew Paris, pp. 615-619.)

In 1288 Pope Nicholas IV. granted the tenths to King Edward I. for six years, towards defraying the expenses of an expedition to the Holy Land; and in order to collect them at their full value, a taxation by the king's precept was begun in that year, and finished, as to the province of Canterbury, in 1291, and as to that of York in the following year, the whole being under the direction of the bishops of Winchester and Lincoln. This taxation is a most important record, because all the taxes of the church, as well to the kings of England as to the pope, were afterwards regulated by it until the survey made by Henry VIII.; and because the statutes of colleges which were founded before the Reformation are also interpreted by this criterion, according to which their benefices, under a certain value, are exempted from the restriction in the statute 21 Henry VIII. concerning pluralities. (*Preface to Taxatio Ecclesiastica, P. Nich. IV., by the Record Commissioners.*)

In 1295 Edward, notwithstanding the pope's grant, and numerous exactions from the clergy in the meantime, being still in great need of money to carry on his wars, summoned deputies from the inferior clergy for the first time to vote him supplies from their own body. In the preceding year he had, by threats and violence, exacted a tax of half the revenues of the clergy; but now he thought it prudent to obtain their consent to his demands in a more regular manner. The clergy however would not obey the king's writ of summons, lest they should appear to acknowledge the temporal power; and in order to overcome this objection, the king issued his writ to the archbishop, who, as their spiritual superior, summoned the clergy to meet in convocation. (Gilbert's *History of the Exchequer*, p. 51; *Hume*, vol. ii., pp. 278, 279.)

This was the commencement of the constitutional practice of the clergy meeting in Convocation at the same time as the Lay Parliament, and voting subsidies by its own voluntary act for the service of the state. It was not viewed without alarm by the pope and the high church dignitaries; and in order to put a stop to all such exactions of princes from the clergy, Pope Boniface VIII. issued a bull in 1296, which, after stating that temporal princes were in the habit of extorting heavy contributions from ecclesiastical persons, who, fearing to offend temporal power more than the eternal, had unwisely acquiesced in such extortions, proceeded to forbid churchmen of every degree to pay any tribute, subsidy, or gift to laymen, without authority from the see of Rome; and declared that if they should pay, or princes exact, or any one assist in levying such unauthorised taxes, all such persons respectively would incur the sentence of excommunication. (Rymer's *Fœdera*, vol. i., part 2, p. 836; Record Commissioners. ed. 1816.)

In the same year however Edward I. demanded of the clergy a fifth of their moveables, which they resisted, on the ground that they could not disobey the pope: but the king was not inclined to desist; and in order to force the acquiescence of the clergy, he put them out of the pale of the laws. Orders were issued to the judges to hear no cause brought before them by the clergy, but to decide all causes in which they were sued by others. The clergy were immediately exposed to violence and spoliation on all sides, in spite of a general sentence of excommunication pronounced by the archbishop against all persons who should attack the persons or property of ecclesiastics. The clergy could not long resist these oppressions; and although they were unwilling to disobey the Papal bull, they evaded it by voluntarily depositing a sum equivalent to the amount

demanded of them in some church, whence it was taken by the king's officers. In this expedient the whole ecclesiastical body acquiesced, and thus yielded up their spiritual privileges, under coercion by the temporal power.

At the Reformation, the chief source of revenue to the pope, viz., first-fruits and tenths, was transferred to the king 'for more augmentation and maintenance of the royal estate of his imperial crown and dignity of supreme head of the church of England.' (Stat. 26 Henry VIII., c. 3.) In order to collect this revenue a court of first-fruits was established, and the king ordered a valuation to be made of all the episcopal sees and benefices in England. The book which contains this valuation is called the 'Liber Regis,' and all the benefices which have not since been exempted still pay first-fruits and tenths according to this valuation. The first-fruits and tenths continued to form part of the royal revenue until Queen Anne, by the Act 2 & 3 of her reign, c. 11, gave up the proceeds thereof on the part of herself and her successors, and assigned them for ever to the augmentation of poor livings.

It now only remains to notice more particularly the practice of taxing the clergy in convocation, which continued in full force till the reign of Charles II. It had afforded the kings of England a lucrative revenue from the church. Their influence as heads of the church, and as having ecclesiastical preferments to bestow, was very great after the Reformation, and enabled them very commonly to obtain larger subsidies from the convocation than those that were voted by parliament. The church therefore was not unwilling to be deprived of the expensive privilege of voting separate subsidies; and acquiesced in an arrangement proposed in 1664-5, by which the Commons have ever since voted taxes upon the possessions of the church and of the clergy, in the same manner as upon the laity. As a boon for this submission of the church to temporal authority, two subsidies which the convocation had granted were remitted, and the parochial clergy were allowed to vote at elections. [CLERGY; CONVOCATION; TITHES.]

TAXES. The general objects, character, and principles of taxation, and of different classes of taxes, are treated of under the head of TAX, TAXATION. In this place it is proposed to give a short summary of the amount and description of taxes paid in this and some other countries, whether assessed directly upon property, or collected indirectly upon articles of consumption; including not only such taxes as are paid to the general government, but also all municipal and local assessments or contributions.

United Kingdom.

The chief sources of revenue are from indirect taxes, as will be seen by the following statement, made up to 5th January, 1842:—

	Gross Receipt. £	Rate per cent. at which collected. £	s.	d.
Customs	23,821,486	5	6	4
Excise	15,477,674	6	7	8½
Stamps	7,494,239	2	3	4
Taxes (Assessed, &c.)	4,720,457	4	2	9½
Post-Office	1,539,274	60	9	6¾
Duties on Pensions and Salaries	5,752	1	17	6½
Crown Lands	438,297	8	18	3½
Small branches of hereditary revenue	5,562			
Surplus fees of public offices	93,504			
Total ordinary revenues	53,596,250	6	13	8¼

To these parliamentary taxes may be added the following local assessments:—

Poor-rates	£6,351,828 (which includes county rates, 700,000*l.*)
Church-rates	600,000 (in round numbers).
Highway-rates	1,312,812
Turnpike-tolls (England and Wales)	1,577,764
Grand-jury presentments (Ireland)	1,265,866
Total of local taxes.	11,108,270

(*Parliamentary Papers*, 1839 (562), 1841 (344) (421), 1842 (135) (235).)

These include all the local taxes of which any account can be given, but there are still many others, such as rates for paving, lighting, and watching particular cities and towns, and for other municipal purposes. It may also be added that the tithes of Great Britain and Ireland amount to 4,000,000*l.*

It is instructive to compare the present amount of taxes with that rendered necessary by a war expenditure. From 1805 to 1818 the payments into the British exchequer from taxes and loans in no one year amounted to less than 100,000,000*l.*, and in 1813 arose to the enormous and scarcely credible sum of 176,346,023*l.*

Denmark.

The total amount of all state and provincial or country commune taxes amounted in 1841 to 2,020,000*l.*, upon a population of 2,100,000.

Sweden.

The state taxes amount to	£753,404
Provincial	522,720
Municipal—Stockholm	28,035
All other towns	50,675
Total	£1,354,834

Kingdom of the Netherlands.

Total of government and provincial taxes £5,368,874

France.

Direct contributions for the state	£11,433,204
,, ,, for the provinces	2,743,131
,, ,, for the communes	337,918
Additional	27,948
Total	£15,842,184
Indirect taxes for the state	£29,544,203
Miscellaneous items	453,738
Other sources of revenue	585,600
General total	£46,425,725

Saxony.

The state taxes are:—

	Prussian Dollars.
Direct	1,063,584
Indirect	1,709,610
	2,073,194 or £310,929

Wirtemberg.

State taxes	£534,445
Provincial and municipal	100,938
Total	£635,383

Baden.

State taxes:—	
Direct	£158,333
Indirect	344,000
Total	£502,333

Bavaria.

Direct state taxes	£511,407
Indirect	895,119
Which, with other sources of income, produce a revenue of	2,501,039

Sardinia.

State taxes:—	
Direct	£500,264
Indirect	1,090,000
Total	£1,590,264

Rome (Papal States).

State taxes:—	
Direct	£497,413
Indirect and Miscellaneous	1,261,989

Kingdom of Naples and Sicily.

Naples:—State taxes (exclusive of Sicily)	£3,994,957
Municipal taxes	155,267
Total	£4,150,224
Sicily:—Direct state taxes	£232,500
Indirect	630,639
Total	£862,869
Municipal taxes	£1,163,212

Portugal.

	£	s.	d.
Crown rents . .	157,964	10	3
Direct taxes . .	668,074	18	6
Indirect taxes . .	1,070,780	4	9
Various rents . .	434,046	7	3
Total . .	£2,330,866	0	9

Further interesting particulars concerning the several taxes of European States will be found in the Parliamentary Paper, No. 227, of 1842, ordered by the House of Commons to be printed, 3rd May, 1842.

TAXODIUM, from *taxus*, the name of a genus of plants belonging to the natural order Coniferæ. The plants of this genus are monœcious. The male flowers are arranged in catkins of a roundish form, disposed in racemose panicles; the pollen of each flower is contained in five cases, which are attached to the scale at its inner face. The female flowers are also arranged in small round catkins, two or three of which are attached near to the base of the spike of the catkins of male flowers. The ovules are two in each receptacle. The fruit is a globose strobule, with peltate angled scales; the seeds are angled with very thick integuments; the embryo, with from 5 to 9 cotyledons. The leaves are linear, disposed in two ranks, and are deciduous. This genus has been distinguished from Cupressus principally on account of the arrangement of its male catkins in racemose panicles, the small number of flowers in the female catkins, and the numbers of cotyledons possessed by the embryo.

This genus is well known through the *Taxodium distichum*, deciduous Cypress, a tree that was introduced into Europe from North America as early as 1640. This species is characterized by two-rowed, flat, deciduous leaves; leafless and panicled male flowers, and somewhat globose strobils. It is an elegant tree, and attains a height of 120 feet in its native soil. The first plant that is mentioned as existing in this country was grown in South Lambeth, and was raised from seeds brought from Virginia. Since then it has been introduced in various parts of Great Britain, and many fine specimens are now to be found. In its native districts in North America it is exceedingly abundant, and in many parts, as in Louisiana, it entirely occupies thousands of acres of the low grounds, which are thence called *cyprières*, or cypress swamps. It is found in Delaware, on the banks of the Indian River, in 38° 50′ N. lat., which is its northern boundary, and, proceeding southward, it is abundant in the swamps of Virginia, the Carolinas, Georgia, and the Floridas.

In America, where the tree grows, its wood is used for all the purposes to which timber is applied. In 1819, according to Michaux, almost all the houses of New Orleans were constructed of the wood of this tree. It is considered very durable, and is employed where this quality is an object. In Louisiana it is used for making the masts and sides of vessels, and also canoes, which are fashioned out of a single trunk, and are said to be more durable than when made from any other wood. The bark of the tree exudes a resin of an agreeable odour and a red colour which is used by the negroes for dressing wounds, but it cannot be obtained in sufficient quantities to constitute an article of commerce. The roots of this tree are remarkable for the production of knobs or protuberances, which are sometimes five or six, and, according to some observers, many more feet in circumference. They have generally a conical form, and are hollow inside, with a covering of red bark, similar to that of the roots. In America, they are called 'cypress knees,' and are used by the negroes for bee-hives.

In the cultivation of the deciduous cypress, a rich moist soil must be selected in a low situation. It may be increased by seeds from the imported cones, or it may be propagated by cuttings, planted in autumn in a moist sand or heath soil, situated in a shady damp place. Layers also, when put down in moist soil, will root freely the first year.

During cultivation, this tree is exceedingly prone to sport, so that no two individuals have precisely the same appearance. On this account, a number of varieties have been named. The most common is the *T. d. patens*, which has horizontal branches. Another, with pendulous branches, is known as *T. d. pendulum*; a third, with pendulous first-year's shoots, as *T. d. nutans*. Other species of the genus have been described, but are not yet used or cultivated. For further information on this genus, see Loudon's 'Arb. et Frut. Brit.,' vol. iv.

TAXUS (*taxus*, Latin), the name of a genus of plants, the type of the natural order Taxaceæ. This genus is monœcious; the perianth of the barren flowers is single at the base; the stamens are numerous, with peltate anthers 6-8-celled, the cells opening beneath. The fertile flowers have a single, urceolate, scaly perianth; no style; and a fleshy drupaceous fruit, perforated at the extremity. The species of this genus are evergreen trees, with numerous, mostly linear, entire leaves. They are natives of Europe and North America.

T. baccata, Common Yew, has its leaves 2-ranked, crowded, linear, flat, with the flowers axillary, sessile; the receptacle of the barren flowers globular. The common yew is well known: it is indigenous to most parts of Europe, and is found in every part of Britain and Ireland. It is seldom seen growing in company with its own species, but alone, or with other species of plants.

The yew is a low tree, the trunk rising three or four feet from the ground, and then sending out numerous spreading branches, forming a head of dense foliage, which, when full grown, may be sometimes 30 or 40 feet high. It is of slow growth, attaining under favourable circumstances a height of 6 or 8 feet in ten years, and 15 feet in twenty years. The tallest yew in England is in the churchyard at Harlington, near Hounslow, which is 58 feet high. A tree continues growing for about one hundred years; it mostly ceases to grow at that age, but will live for many centuries. The yew-trees at present existing at Fountain's Abbey in Yorkshire are supposed to have attained their full growth when the abbey was erected in 1132.

The remarkable characters and properties of the yew have drawn towards it at all times much attention. Dioscorides, Pliny, and Theophrastus mention its poisonous properties. Cæsar (*Bell. Gall.*, vi. 31) relates that Cativolcus, king of the Eburones, committed suicide by swallowing the juice of the yew. Plutarch says that its fruit is poisonous, and that its shade is fatal to all who sleep under it. This is also stated by Pliny; but there must have been some mistake on some of these points, as it is now well known that the fruit of the yew may be eaten with impunity, and that its shade is not more deadly than that of other trees.

The yew appears to have been employed from the earliest times in the manufacture of bows, and was used for this purpose by the nations of antiquity. The bows used by the English previous to the introduction of gunpowder were made of yew, and there are many allusions amongst English poets to this use of its wood. The battles of Cressy and Poictiers were gained by the English yew-bows, and the same weapon was used in the wars of York and Lancaster. In the course of time the supply of yew was deficient, and other woods came to be used; but the introduction of gunpowder soon after put a stop to the use of the bow as a weapon of war altogether. Bows are now seldom made of the yew, various ornamental woods from South America being preferred. In Switzerland the yew tree is called William's tree, because the bow of William Tell is said to have been made of that wood. The yew is a common ornament of the churchyard. The origin of the practice of planting this tree in such situations is not at all clearly made out. Their dark foliage and supposed deadly shade may have pointed them out as the fit emblems of silence and death. Mr. Bowman (*Magaz. of Nat. Hist.*, vol. i.) observes that 'it seems most natural and most simple to believe, that being indisputably indigenous, and being, from its perennial verdure, its longevity, and the durability of its wood, at once an emblem and a specimen of immortality, its branches would be employed by our pagan ancestors, on their first arrival here, as the best substitute for the cypress to deck the graves of the dead, and for other sacred purposes.'

The yew used to be frequently planted in gardens as an ornament, on account of the facility with which it may be cut into various fantastic shapes. During the past century it was not uncommon to meet with these trees cut into the forms of balls, pyramids, beasts, birds, and men; but this practice having fallen under the well-merited censure of Pope and other writers, only a remnant of it here and

there is seen at the present day. Although the fruit of the yew is not poisonous, there are many well-authenticated instances of the leaves producing death. Deer and goats are said to feed upon them with impunity, but to cows and horses they prove an active poison. The yew has not been at any time used generally as a medicine, although its effects on the system have been represented as similar to those of digitalis, and as being more manageable and less liable to accumulate in the system than that medicine. Professor Wiborg of Copenhagen states that the leaves of the yew are only poisonous to animals when they are eaten alone, but that if eaten with three or four times the quantity of other food they are innocuous.

There are several remarkable specimens of old yews existing in this country. Those at Fountains Abbey are said to have sheltered the monks whilst that magnificent pile was erecting. The Tytherley, Fortingal, Arlington, and Loch-Lomond yews are remarkable for their size and age. Many of them, if we estimate their age in the mode proposed by De Candolle, must exceed considerably a thousand years.

The wood of the yew is used extensively in cabinet-making. It is very hard, compact, and of a fine close grain, which arises from the smallness of its annual layers, 280 being sometimes found in a piece not more than 20 inches in diameter. It is also much used by the turner for making snuff-boxes, musical instruments, &c.

There are several varieties of the common yew; the most remarkable is the Irish yew, which Professor Lindley has made a distinct species, *Taxus fastigiata*. It is distinguished by its upright mode of growth, and by its leaves not being arranged in ranks, but scattered. It was first discovered at Florence Court, on the mountains of Fermanagh, and has since been observed in other parts of Ireland. Other varieties are described, produced by difference in cultivation, soil, &c. The Canada or North American yew is described as a species, *T. Canadensis*. The leaves are narrower and smaller than those of the common yew, and are revolute at the margin, and the male flowers are solitary in the axis of the leaves. It is found native in Canada, and on the banks of a river in Maryland.

In the cultivation of the yew, a moist soil should always be selected; but it thrives best on clays and loams, on rocks, and in shady places. It is best propagated by seeds, which, if sown as soon as they are gathered in autumn, surrounded by the pulp of the fruit, will come up the next or following spring; but if dried, will not come up till the third year. Where the object is to form a fence, cuttings may be employed. Before transplanting, whether they be raised from seeds or cuttings, the plants should be three or four feet high.

For further information concerning the yew, see Loudon's *Arboretum et Fruticetum Britannicum*.)

TAY, River. [PERTHSHIRE.]

TAY, LOCH. [PERTHSHIRE.]

TAYGETUS. [LACONIA.]

TAYLOR, ROWLAND, LL.D., was a clergyman eminent for his learning and piety, who was burnt at the stake in the reign of Queen Mary. He is said by Bishop Heber to have been an ancestor of Jeremy Taylor. He was chaplain to Archbishop Cranmer, by whom he was appointed rector of Hadleigh, in Suffolk, where he went to reside.

Dr. Taylor was summoned, in the year 1553, to appear in London before Gardiner, bishop of Winchester, who was then lord chancellor, for resisting the performance of mass in his church at Hadleigh. He was strongly persuaded to escape, but refused, and presented himself before Gardiner, by whom, after a long conference, in which he defended his cause with unshrinking firmness, he was committed to the King's Bench prison. There he remained till the 22nd of January, 1555, when he and other prisoners were cited before Gardiner, and the bishops of London, Norwich, Salisbury, and Durham, who were joint commissioners with the chancellor. The chief offence of which Dr. Taylor was now accused was his marriage; but he defended the right of priests to marry with so much learning, that no sentence of divorce was pronounced, though he was deprived of his benefice. At the end of January the prisoners were again brought before the commissioners, by whom they were sentenced to death. Dr. Taylor was committed to the Poultry Compter, where, on the 4th of February, he was visited by Bonner, bishop of London, who went there for the purpose of making him put on the dress of a Roman Catholic priest. Dr. Taylor resisted with his usual courage, and the dress was put upon him by force: he treated the whole proceeding with the utmost contempt, as a piece of mummery, and Bonner would have struck him with his crosier if he had not been restrained by his chaplain. On the following day the procession set forth which was to conduct him to the place of execution. In the course of the journey much persuasion was used by the sheriff and others to induce him to recant, but without making the smallest impression upon him. The procession passed through Hadleigh, where he was consoled and cheered by the blessings and prayers of his parishioners. The execution took place on the 8th of February, 1555, on Aldham Common, near Hadleigh. A stone, with the following inscription, perhaps still remains to mark the spot:—'1555. Dr. Tayler in defending that was gode at this plas left his blode.'

Bishop Heber, in his 'Life of Bishop Jeremy Taylor,' says, 'There is nothing indeed more beautiful in the whole beautiful Book of Martyrs than the account which Fox has given of Rowland Taylor, whether in the discharge of his duty as a parish priest or in the more arduous moments when he was called on to bear his cross in the cause of religion. His warmth of heart, his simplicity of manners, the total absence of the false stimulants of enthusiasm or pride, and the abundant overflow of better and holier feelings, are delineated, no less than his courage in death and the buoyant cheerfulness with which he encountered it, with a spirit only inferior to the eloquence and dignity of the "Phædon."'

(Fox's *Acts and Monuments*.)

TAYLOR JEREMY, was born at Cambridge in 1613, where he was baptized on the 15th August in that year. His ancestors had been wealthy and respectable, one of whom, Dr. Rowland Taylor, is mentioned in Fox's 'Book of Martyrs' as bringing upon himself the persecution of the popish party in the reign of Mary, not only by the popularity of his character and talents, but also his wealth. Taylor's father was a barber, a calling generally united in those days with surgery. At an early age Taylor was sent to Perse's grammar-school in Cambridge, and in his fourteenth year he was entered at Caius College as a sizar, an order of students which, Bishop Heber informs us, were then what the 'servitors' still continue to be in some colleges in Oxford, and what the 'lay brethren' are in the convents of the Romish church. At little more than twenty years of age, having taken the degree of master of arts, and been admitted to holy orders, he attracted the notice of Laud, then archbishop of Canterbury, before whom he was invited to preach at Lambeth. Laud appreciated his eloquence and his talents, which he encouraged in the most judicious manner by having him settled at Oxford, where he was admitted to the degree of master of arts, and by the powerful interposition of the archbishop, in 1636, nominated to a fellowship. Taylor does not appear to have remained long or uninterruptedly at Oxford. In 1637-8 he was presented by Juxon, bishop of London, to the rectory of Uppingham in Rutlandshire. About this time an acquaintance which, in common with Laud, he maintained with a learned Franciscan friar, Francis à Sancta Clara, exposed him to the suspicion of a concealed attachment to the Roman church—a suspicion to which the character of his mind, which tended to asceticism in religion, and to an extravagant veneration for antiquity, and which cherished a love of the gorgeous and imposing in the ceremonial of worship, gave some plausibility. At a later period in life however Taylor solemnly denied that there had ever been any solid ground for questioning the sincerity of his Protestantism.

In the civil wars he followed the fortunes of Charles, whose chaplain he was, and in 1642, when the king was at Oxford, he published there his 'Episcopacy asserted against the Acephali and Aerians New and Old,' in which he sought to maintain a cause that had then however, unfortunately, passed from the controversy of the pen to that of arms. Charles rewarded Taylor in the only way which it remained in his power to do, by commanding his admission to the degree of doctor of divinity. This honour was diminished by the indiscriminate manner in which it was conferred upon many other loyalists at the same time, so as to provoke an expression of dissatisfaction from the

heads of the University; and its advantages were overbalanced by the loss which Taylor encountered in the same year, in the sequestration of his rectory of Uppingham by the parliament. In 1647, when the crisis of the civil war impended, he published his discourse, 'The Liberty of Prophesying.' After the defeat of the royalists Taylor was repeatedly imprisoned, but only for short periods. During the first years of the protectorate he supported himself by keeping a school, in Wales, in company with Nicholson, afterwards bishop of Gloucester, and Wyat, afterwards prebendary of Lincoln, by his occasional writings, and by whatever contribution the friendship of the earl of Carbery, on whose estate he exercised his ministry, might afford to him. In the year 1658 he was encouraged by Lord Conway to settle in Ireland, where he divided his residence between Lisburn and Portmore, and he officiated in the ministry at both these places. The provision which he received was however so inadequate to his wants, that he was obliged to remain under obligations to his friend John Evelyn, who generously allowed him a yearly pension. In the obscurity of Portmore Taylor did not escape the unhappy persecutions of that period. He was charged by an informer with having used the sign of the cross in baptism, and dragged before the Irish privy council, from a distance and in the middle of a severe winter, to be examined. A fever was the consequence of his arrest, which probably induced the council to act leniently towards him.

In 1660 he travelled to London to prepare for publication his 'Ductor Dubitantium,' when he attached his signature to the declaration of the royalists, dated April 24th, in which they expressed the moderation of their views, and their confidence in the wisdom and justice of Monk. Taylor was thus favourably brought under the notice of Charles II., whose restoration took place this year, and to whom he dedicated the 'Ductor Dubitantium.' The king nominated him under the privy seal to the bishopric of Down and Connor, to which he was consecrated in January, 1661: in the following month he was made a member of the Irish privy council; and in the next, in addition to his original diocese, he was intrusted with the administration of the small adjacent one of Dromore, on account, in the words of the writ, 'of his virtue, his wisdom, and industry.' In the course of the same year he was elected vice-chancellor of the University of Dublin. Bishop Heber has deemed it necessary to account for Taylor's not having received an English bishopric. Besides his eminent abilities, and his faithful adherence to the cause of the church and the king, he had married the natural daughter of Charles I., who was his second wife, and then living. This last circumstance however, if pleaded with the king in favour of preferment for Taylor, as Bishop Heber thinks, may have contributed to determine the scene of his promotion: 'Charles may not have been unwilling to remove to a distance a person whose piety might have led him to reprove many parts of his conduct, and who would have a plausible pretence for speaking more freely than the rest of the dignified clergy.'

The new station which Taylor was called upon to fill had peculiar and great difficulties connected with it. In the revolution through which religion had passed, livings had been conferred on men whose feelings were at variance with episcopacy, and they had to be conciliated to a willing obedience, or, as time proved, to submit to the severest test of principle in the sacrifice of their emoluments. In Ireland there were additional circumstances to contend with. The Episcopal or Protestant church was unpopular; the preachers were almost exclusively English; the ritual was English, and to the mass of the natives unintelligible; there was no translation of the Scriptures, and yet attendance at the established churches was compulsory. Bishop Taylor laboured with much zeal and energy for the establishment of the Protestant religion; but with little effect. He was attacked by fever on the 3rd August, 1667, at Lisburn, and died in ten days, in the fifty-fifth year of his age, and the seventh of his episcopacy. The children of his first wife died before him; by his second, who survived him, he left three daughters.

The writings of Jeremy Taylor may be brought under four descriptions: practical, theological, casuistic, and devotional. The first comprises his 'Life of Christ,' which he published in 1653; 'Contemplations on the State of Man,' a posthumous work; 'Holy Living and Holy Dying,' 1651; and his Sermons, which appeared at various periods. A work entitled 'Christian Consolation' has been referred to him, and published in the collected edition of his writings by Bishop Heber in 1820-2; but it has since been published in the name of Bishop Hackett, who appears to have been its true author. The second comprises his 'Episcopacy asserted against the Acephali and Aerians New and Old,' 1642; 'An Apology for Authorized and Set Forms of Liturgy,' 1644; his 'Discourse of the Liberty of Prophesying, with its just limits and temper; showing the unreasonableness of prescribing to other men's faith, and the iniquity of persecuting differing opinions,' 1647; the 'Unum Necessarium; or the Doctrine and Practice of Repentance,' 1665; 'Deus Justificatus, or a Vindication of the Glory of the Divine Attributes in the question of Original Sin, against the Presbyterian way of understanding it,' 1656; 'The Real Presence and Spiritual of Christ in the Blessed Sacrament, proved against the Doctrine of Transubstantiation,' 1654; 'A Dissuasive from Popery,' 1664. The third includes his 'Discourse of the Nature, Offices, and Measures of Friendship, with Rules of Conducting it,' 1657; and the 'Ductor Dubitantium, or Rule of Conscience in all Her general Measures,' 1660. The fourth comprises his 'Clerus Domini, or a Discourse of the Divine Institution, Necessity, Sacredness, and Separation of the office Ministerial, together with the Nature and Manner of its Power and Operation,' 1651; 'The Golden Grove, or a Manual of Daily Prayers and Litanies, fitted to the Days of the Week,' 1654; 'The Psalter of David, with Titles or Collects, according to the Matter of each Psalm,' 1644; 'A Collection of Offices or Forms of Prayer in cases ordinary and extraordinary; taken out of the Scriptures, and the Ancient Liturgies of several Churches, especially the Greek,' 1658; 'Devotions for Various Occasions;' and 'The Worthy Communicant, or a Discourse of the Nature, Effects, and Blessings consequent to the worthy receiving of the Lord's Supper, and of all the Duties required in order to a worthy preparation; together with the Cases of Conscience occurring in the duty of him that ministers and of him that communicates,' 1660.

Mr. Hallam ranks the Sermons of Bishop Taylor 'far above any that had preceded them in the Church of England. An imagination essentially poetical, and sparing none of the decorations which by critical rules are deemed almost peculiar to verse; a warm tone of piety, sweetness, and charity; an accumulation of circumstantial accessories whenever he reasons, or persuades, or describes; an erudition pouring itself forth in quotation till his sermons become in some places almost a garland of flowers from all other writers, and especially from those of classical antiquity, never before so redundantly scattered from the pulpit, distinguish Taylor from his contemporaries by their degree, as they do from most of his successors by their kind. His sermons on the Marriage Ring, on the House of Feasting, on the Apples of Sodom, may be named without disparagement to others, which perhaps ought to stand in equal place. But they are not without considerable faults, some of which have just been hinted. The eloquence of Taylor is great, but it is not eloquence of the highest class; it is far too Asiatic, too much in the style of Chrysostom and other declaimers of the fourth century, by the study of whom he had probably vitiated his taste; his learning is ill-placed, and his arguments often much so; not to mention that he has the common defect of alleging nugatory proofs; his vehemence loses its effect by the circuity of his pleonastic language; his sentences are of endless length, and hence not only altogether unmusical, but not always reducible to grammar. But he is still the greatest ornament of the English pulpit up to the middle of the seventeenth century; and we have no reason to believe, or rather much reason to disbelieve, that he has any competitor in other languages.' (Hallam's *Introduction to the Literature of Europe*, vol. iii., c. ii., p. 125-6.)

He has been accused of having copied a work of a similar character by Ludolphus de Saxonia, a Roman Catholic writer, in his 'Life of Christ;' but Bishop Heber, who had examined both works, asserts that there is scarcely any resemblance between them, and none which authorizes the imputation of plagiarism.

'The Liberty of Prophesying' (that is of interpretation) is the most popular in the second division of Taylor's writ-

ings. A very good sketch of it will be found in the third volume of Mr. Hallam's 'Introduction to the Literature of Europe, and a more detailed one in the first volume of Heber's edition of Taylor's works. But the discourse itself is not long, and will well repay the reading. It considerably diminishes the admiration with which we are disposed to connect this production of Taylor with the man, his order, and the times, when we take into account the motives which he afterwards assigned for its publication. 'In the dedication to Lord Hatton of the collective edition of his controversial writings after the Restoration, he declares that when a persecution did arise against the Church of England, he intended to make a reservation for his brethren and himself, by pleading for a liberty to our consciences to persevere in that profession, which was warranted by all the laws of God and our superiors.' (Hallam, *Introduction to the Literature of Europe*, vol. iii., p. 116.) Bishop Heber has vindicated Taylor from the charge of tergiversation, founded not upon the above testimony which Taylor himself furnishes, but upon the character of his proceedings when episcopacy was restored. If we must allow in reference to his Sermon preached before the Irish Privy Council, that the obedience which he there insists upon is only, as Bishop Heber suggests, that obedience to the laws of ecclesiastical superiors which is paid by the members (clergy) of their own communion; and that it is in fact no more than the privilege (which every Christian society exerts and must exert for its own preservation) to have the offices of its ministry supplied by such men as conform to the regulation imposed by the body at large on those to whom its powers are delegated; we ought to add that this distinction is left in much ambiguity; that principles are maintained with a much more general signification than this explanation allows; and, in one word, upon ninety-nine out of a hundred readers the sermon before the Irish Privy Council would produce impressions totally inconsistent with those derived from the 'Discourse on the Liberty of Prophesying.' After expressing his sorrow at seeing the horrid mischiefs which come from rebellion and disobedience, and his hopes of better things, the bishop of Down and Connor proceeds in his sermon before the Privy Council to say that he sees no objection 'against his hopes but that which ought least of all in this case to be pretended: men pretend conscience against obedience, expressly against St. Paul's doctrine teaching us to obey for conscience sake; but to disobey for conscience in a thing indifferent is never to be found in the books of our religion. It is very hard when the prince is forced to say to his rebellious subjects, as God did to his stubborn people, 'Quid faciam tibi?' 'I have tried all the ways I can to bring thee home, and what shall I now do unto thee?' The subject should rather say, 'Quid me vis facere?' 'What wilt thou have me to do?' This question is the best end of disputations. 'Corrumpitur atque dissolvitur imperantis officium, si quis ad id quod facere jussus est, non obsequio debito, sed consilio non considerato, respondeat,' said one in A. Gellius: When a subject is commanded to obey, and he disputes, and says, 'Nay, but the other is better,' he is like a servant that gives his master necessary counsel when he requires of him a necessary obedience. 'Utilius parere edicto quam efferre consilium;' 'he had better obey than give counsel;' by how much it is better to be profitable than to be witty, to be full of goodness rather than full of talk and argument.' Farther on, in the same sermon, he distinguishes between a 'tender conscience,' which is such in reference to age or ignorance, or of 'new beginners,' and that which is the 'tenderness of a boil; that is soreness indeed, rather than tenderness, is of the diseased, the abused, and the mispersuaded.' The first is to be dealt tenderly with. 'But for that tenderness of conscience which is the disease and soreness of a conscience, it must be cured by anodynes and soft usages, unless they prove ineffective, and that the lancet may be necessary.'

Mr. Hallam refers to the 'Ductor Dubitantium' as the most extensive and learned work on casuistry which has appeared in the English language. 'As its title shows, it treats of subjective morality, or the guidance of the conscience. But this cannot be much discussed without establishing some principles of objective right and wrong, some standard by which the conscience is to be ruled. "The whole measure and rule of conscience," according to Taylor, "is the law of God, or God's will signified to us by nature or revelation; and by the several manners and times and parts of its communication it hath obtained several names: the law of nature, the consent of nations, right reason, the Decalogue, the sermon of Christ, the canons of the apostles, the laws ecclesiastical and civil of princes and governors, expressed by proverbs and other instances and manners of public honesty. . . . These being the full measures of right and wrong, of lawful and unlawful, will be the rule of conscience and the subject of the present book." The heterogeneous combination of things so different in nature and authority, as if they were all expressions of the law of God, does not augur well for the distinctness of Taylor's moral philosophy, and would be disadvantageously compared with the Ecclesiastical Polity of Hooker. Nor are we deceived in the anticipations we might draw. With many of Taylor's excellencies, his vast fertility, and his frequent acuteness, the "Ductor Dubitantium" exhibits his characteristic defects; the waste of quotations is even greater than in his other writings, and his own exuberance of mind degenerates into an intolerable prolixity. His solution of moral difficulties is often unsatisfactory; after an accumulation of argument and authorities we have the disappointment to perceive that the knot is neither untied nor cut; there seems a want of close investigation of principles, a frequent confusion and obscurity, which Taylor's two chief faults, excessive display of erudition and redundancy of language, conspire to produce. . . . Taylor seems inclined to side with those who resolve all right and wrong into the positive will of God. The law of nature he defines to be "the universal law of the world or of mankind, to which we are inclined by nature, invited by consent, prompted by reason, but which is bound upon us only by the command of God." Though in the strict meaning of the word law, this may be truly said, it was surely required, considering the large sense which that word has obtained as coincident with moral right, that a fuller explanation should be given than Taylor has even intimated, lest the goodness of the Deity should seem something arbitrary and precarious. And, though, in maintaining against most of the scholastic metaphysicians that God can dispense with the precepts of the Decalogue, he may be substantially right, yet his reasons seem by no means the clearest and most satisfactory that might be assigned. It may be added, that in his prolix rules concerning what he calls a probable conscience, he comes very near to the much-decried theories of the Jesuits. There was indeed a vein of subtlety in Taylor's understanding which was not always without influence on his candour.' (*Introduction to the Literature of Europe*, chap. iv., vol. iv.)

Bishop Heber has also remarked on some of Taylor's positions to the same effect; instancing his admission that private evil may be done by public men and for the public necessity; his justification on moral grounds of the supposed fraud of the children of Israel in borrowing jewels of the Egyptians without any intention of restoring them. 'In the first chapter of the third book, which treats of human laws and their obligations, a case occurs in illustration of Rule iv., that "a law founded on a false presumption does not bind the conscience," in which the Romish canonists seem to have given a more just decision than Taylor: Biretti, a Venetian gentleman, pretends a desire to marry Julia Mediei, the daughter of a neighbour, with a purpose to seduce and desert her. A contract is made; but before its execution he gains his end, and, leaving her, marries another. The canonists declare the former contract, followed by congress, to be a marriage, and that he is bound to return to Julia. "No," says Taylor, "if he did not lie with her, 'affectu maritali,' "he was extremely impious and unjust; but he made no marriage; for without mutual consent marriages are not made."' To these illustrations, adduced by Heber, may be added another, referred to elsewhere: Rule xi., 484, he maintains the right of using arguments and authorities in controversy which we do not believe to be valid; a rule of which he appears to have taken advantage; for, 'in the *Defence of Episcopacy*, published in 1642, he maintains the authenticity of the first fifty of the apostolic canons, all of which, in the "Liberty of Prophesying," a very few years afterwards, he indiscriminately rejects.' (Hallam.)

On devotional subjects the character of Taylor's mind fitted him to write with most success. In these we find his most glowing language, his aptest illustrations; and

'whether he describes the duties, or dangers, or hopes of man, or the mercy, power, and justice of the Most High; whether he exhorts or instructs his brethren, or offers up his supplications in their behalf to the common Father of all, his conceptions and his expressions belong to the loftiest and most sacred description of poetry, of which they only want what they cannot be said to need, the name and the metrical arrangement.' (Heber, *Life and Works of Jeremy Taylor*, 15 vols., 1820-22.)

TAYLOR, JOHN, best known by the title, which he seems to have given to himself, of *The Water-Poet* ('The King's Majesty's Water-Poet'), was born in the city of Gloucester in the year 1580. His education was limited, for he himself informs us that he was 'gravelled' in his 'Accidence,' and could get no farther. He came to London, and was bound apprentice to a waterman, an occupation from which he derived his title of 'Water-Poet,' and which afforded him the means of subsistence during a great part of his life. He had however for fifteen or sixteen years some situation in the Tower of London; and he afterwards kept a public-house in Phœnix-Alley, Long Acre. Being an enthusiastic royalist, when Charles I. was beheaded he hung up the sign of the Mourning Crown, which however he was compelled to take down, and he then supplied its place by a portrait of himself, with the following couplet under it:—

'There's many a king's head hang'd up for a sign,
And many a saint's head too: then why not mine?'

Taylor was not satisfied with the distinction which his literary productions procured for him: he was fond of fixing public attention by other extraordinary performances. He once undertook to sail from London to Rochester in a boat made of paper, but the water found its way into his boat before he reached his destination, and he had some difficulty to get safe ashore. A journey which he performed by land is described in one of his tracts, entitled 'The Pennyless Pilgrimage, or the Moneyless Perambulation of John Taylor, alias the King's Majesty's Water-Poet; how he travelled on foot from London to Edinburgh in Scotland, not carrying any money to or fro, neither begging, borrowing, or asking meat, drink, or lodging.' He left 'the Bell Inn that's extra Aldersgate' on the 14th of July, 1618. A full account of this journey, abstracted from Taylor's pamphlet, is given in the 'Penny Magazine,' Nos. 622 and 623. He was attended by a servant with a horse, and they had a small stock of provisions and provender, which more than once relieved them when the occasional inhospitality which they met with had reduced them to the extremity of hunger. His course was through St. Albans, Stony Stratford, Coventry, Lichfield, Newcastle-under-Lyne, Manchester, Preston, Lancaster, Penrith, Carlisle, Edinburgh, Dunfermline, Stirling, Perth; and being then in the Highlands, he had an opportunity of seeing, at 'the Brae o' Mar,' one of those great deer-hunts which were then frequent in that part of Scotland, and of which he gives in his pamphlet an entertaining and picturesque description. The whole journey till his return to London occupied about three months. But a sort of voyage which he afterwards performed was apparently not less difficult. He published, as usual, an account of it himself, 'John Taylor's last Voyage and Adventure, performed from the 20th of July last, 1641, to the 10th of September following; in which time he passed with a sculler's boat from the citie of London to the cities and townes of Oxford, Gloucester, Shrewsbury, Bristol, Bathe, Monmouth, and Hereford.' From this title it might be supposed that he went all the way by water, a feat which, seeing the courses of the rivers, and the want of canals in those days, was an obvious impossibility; but the fact is, that when a river ceased to be navigable, or ran in a wrong direction, he shipped his boat and himself in a wain or waggon, and voyaged overland till he came to another river which suited his purpose: still a great part of the voyage was performed by water, and thus, to use his own words, 'in lesse than twenty days' labour, 1200 miles were passed to and fro, in most hard, difficult, and many dangerous passages.'

Taylor died in 1654, in his 75th year, and was buried in the church-yard of Covent-Garden, London.

His publications, which amount to upwards of eighty, are some in prose, some in verse, and many both in prose and verse. As literary productions they are of little or no value, the verse mere doggrel, and the prose such as might be expected from a writer not without observation, but of no great power of mind, and almost entirely uneducated. Still they are by no means without their value. Nearly all of them being short occasional productions arising out of the circumstances in which he was placed, they afford many curious descriptions, as well as interesting glimpses of the opinions and manners and general state of society of the times in which he lived. Sir Egerton Brydges, in his 'Censura Litteraria,' has given a full list of Taylor's writings, and a tolerably copious one is also given in Watt's 'Bibliotheca Britannica.'

(Baker's *Biographia Dramatica*, by Reed and Jones, in which work he has obtained a place in consequence of having written a pageant, 'Triumphs of Fame and Honour,' 4to., 1634.)

TAYLOR, SILAS, otherwise called Domville, or D'Omville, by Antony Wood, was the son of Sylvanus Taylor, one of the commissioners during the civil wars for ejecting those of the clergy called 'scandalous and insufficient ministers.' Silas Taylor was born at Harley near Much-Wenlock, in Shropshire, July 16, 1624, and after being educated at Shrewsbury and Westminster schools, became a commoner of New Inn Hall at Oxford in 1641. He was taken thence by his father to join the parliamentary army, in which he had a captain's commission. After the war he was appointed by the interest of his father sequestrator of the royalists in Herefordshire, in discharge of which office he conducted himself with so much moderation as to conciliate the king's party. Part of the bishop's palace at Hereford fell to his own share in the general spoliation, and he acquired considerable wealth, all of which he was compelled to restore at the Restoration.

On that event he was treated by the royalists with great lenity, and appointed commissary of ammunition, &c. at Dunkirk, and about 1665 made keeper of the king's stores and storehouses for shipping at Harwich. He died November 4, 1678, and was buried at Harwich. Taylor was much interested in the antiquities of his country, and was enabled in the confusion of the civil wars to ransack the libraries of Hereford and Worcester cathedrals, and in the course of these researches is said to have discovered the original charter in which King Edgar asserts his claim to the sovereignty of the seas, which is printed in Selden's 'Mare Clausum,' lib. ii. He left materials for a history of Herefordshire, which afterwards came into the hands of Sir Edward Harley of Brampton Brian in that county. To this collection belong Nos. 4046, 4174, 6726, 6766, 6856, and 6868 of the Harleian MSS., containing part of a general history with notes and special topographical information under the several parishes, extracts from 'Domesday,' Leland, &c. From these papers Mr. William Brome, a subsequent collector for the same county, is said to have borrowed largely. (Gough, *Catalogue of Topographical Works*, 'Herefordshire.') In the Sloane MSS. is a paper of Taylor's on the making of cider. (Ayscough's *Catalogue*, 'Taylor.')

His published works are, 'The History of Gavelkind—with some observations and remarks upon many special occurrences of British and English history. To this is added a short history of William the Conqueror, written in Latin by an anonymous author in the time of Henry I.,' London, 1663, 4to.

A History of Harwich was published from his papers by Samuel Dale, in 1730, and another edition, or the same with another title-page, London, 1732.

Wood (*Athen. Oxon.*) states, that Taylor wrote many pamphlets before the Restoration, but without his name; that he was a good classical scholar and mathematician, and possessed of much general information; that he was an excellent musician, and that he composed several anthems, and edited 'Court Ayres,' &c., 1655, 8vo., printed by John Playford.

TAYLOR, BROOK; TAYLOR'S THEOREM. In referring all matters connected with algebraical development to TAYLOR'S THEOREM, we were partly moved by the idea that so little was known of the life of the discoverer of that theorem, that the additional space required by our plan would not appear more than was due to the celebrity of the subject. We find ourselves however very much deceived in two points, since both the history of Taylor himself, and that of his theorem, are to be, and can be, recovered from the neglect into which they have fallen, at least in this country.

Nothing is said of Brook Taylor in the 'Biographia Britannica,' or Martin's 'Biographia Philosophica;' and Hutton, &c., give nothing but the date of his birth and death, entrance into college and the Royal Society. The 'Biographie Universelle' was the first work which gave any detail of his life, and this is due to the following circumstance:—In 1790, some members of the French Academy, struck with the scantiness of the existing information relative to so celebrated a man, requested Mr. William Seward to make some inquiry on the subject in England. This gentleman applied to Sir William Young, Brook Taylor's grandson, who accordingly drew up an account* of his ancestor from family materials, and printed and circulated it privately. It is from this work that the following account is taken, as to the facts of his private life:—

Brook Taylor was born at Edmonton, August 18, 1685, and was the son of John Taylor, of Bifrons House in Kent, by Olivia, daughter of Sir Nicholas Tempest, of Durham, Baronet. John Taylor was the son of Nathaniel, who, to use a phrase of his own† diary, 'tugged and wrestled with the Lord in prayer,' and was member (elected by Cromwell's summons) for the county of Bedford in the (Barebones) parliament of 1653. Brook Taylor's father was the most despotic of parents: his son was educated at home, where, besides enough of the usual learning to enable him to begin residence at St. John's, Cambridge, in 1701, he became excellent both in music and painting. 'His numerous family were generally proficient in music, but the domestic hero of the art was the subject of this memoir. In a large family picture he is represented, at the age of thirteen, sitting in the centre of his brothers and sisters, the two elder of whom crown him with laurel bearing the insignia of harmony.' The paintings of the future writer on perspective are represented as not needing the allowance always made for amateurs, but as capable of bearing the closest scrutiny of artists. At Cambridge he applied himself to mathematics, and acquired early the notice of Keil, Machin, and others. His first writing was on the centre of oscillation, in 1708, as appears by a letter to Keil (afterwards given in *Phil. Trans.*, 1713, No. 337). In 1709 he took the degree of LL.B., in 1714 that of LL.D.: in 1712 he was elected to the Royal Society. As yet he had published nothing: his letters to Machin (preserved in his family), from 1709 to 1712, treat of various subjects; and, in particular, contain a solution of Kepler's problem. We may here conveniently put together a complete list of his works.

In the *Philosophical Transactions*, 1712 (No. 336), On the ascent of water between two glass planes; 1713 (No. 337), On the centre of oscillation; also on the motion of a vibrating string: in the same year, a paper on Music, not printed. 1713 (No. 344), Account of experiment made with Hawksbee on the law of attraction of the magnet. 1717 (No. 352), Method of Approximation to the roots of equations; (No. 353) Appendix to Montmort on infinite series; (No. 354) Solution of a problem proposed by Leibnitz. 1719 (No. 360), Reply to the accusations of John Bernoulli. 1721 (No. 367), Propositions on the parabolic motion of projectiles; (No. 368) Experiments on magnetism. 1723 (No. 376), On the expansion of the thermometer. Besides these, the separate publications are:—

1715. Methodus incrementorum directa et inversa. Londini.

1715. Linear perspective, or a new method of representing justly all manner of objects as they appear to the eye in all situations. London.

1719. New principles of Linear perspective, or the art of designing on a plane the representations of all sorts of objects in a more general and simple method than has been done before. London. A different work from the former: its second edition (called the third, by an obvious mistake) bears 'revised and corrected by John Colson, London, 1749.' Joshua Kirby's well-known work, though called Brook Taylor's perspective, is not an edition of Taylor, but a new work founded on his methods.

* 'Not published. Contemplatio Philosophica, a posthumous work of the late Brook Taylor, LL.D., F.R.S., some time secretary of the Royal Society. To which is prefixed a Life of the author, by his grandson, Sir William Young, Bart., F.R.S., A.S.S., with an appendix, containing sundry original papers, &c., London, printed by W. Bulmer and Co., Shakspeare Printing-office, 1793.' The account given by Prony in the 'Biographie Universelle' (1826) is, we are almost sure, one drawn up at the time from Sir W. Young's manuscript account as forwarded to Paris; with parenthetical sentences inserted just before publication.

† His grandson's baptismal name was probably in memory of the noted puritan, Lord Brook.

In January, 1714, he was chosen secretary of the Royal Society. In 1716 he visited his friends Montmort and Conti at Paris. He had just had a warm correspondence with the former on the Newtonian doctrine, and on the tenets of Malebranche.* His posthumous work, or rather tract, the 'Contemplatio Philosophica,' seems to contain his latest thoughts on the opinions of Malebranche and Leibnitz. In France he formed the acquaintance of Bishop Bossuet and Lord and Lady Bolingbroke, with all of whom Sir W. Young has printed some of the correspondence. He returned to England in February, 1717; but his health was now impaired, and, throwing up the secretaryship in October, 1718, he retired to Aix-la-Chapelle. On returning to England early in 1719, he seems to have abandoned the mathematics almost entirely: among his papers of this period are essays on Jewish Sacrifices, and on the lawfulness of eating blood. At the end of 1720 he went to visit Lord Bolingbroke at La Source, near Orleans, and returned to England in 1721. After the middle of this year he wrote nothing for publication, nor could his grandson find anything of a mathematical character among his papers, with the exception of reference to a treatise on logarithms, which it seems he had placed in the hands of his friend Lord Paisley (afterwards Abercorn) to prepare for the press, but which was never printed.

At the end of 1721 he married a young lady of small fortune, a circumstance which occasioned a rupture with his father. Some months after his marriage, and when there appeared hope of issue, his wife was informed that the birth of a son would probably accomplish a reconciliation between her husband and his father. On this she fixed her mind with such earnestness, that on finding herself in due time actually delivered of a son, she 'literally died of joy:' the infant also perished. This melancholy event led to the reconciliation the hope of which had caused it, but not till the autumn of 1723. Dr. Taylor returned to his father's house, and in 1725, with his father's consent, married the daughter of a neighbouring proprietor. In 1729 he succeeded to the family estate by the death of his father, and in the following year his wife died in giving birth to a daughter, afterwards the mother of the writer of the memoir from which we cite. This blow was fatal; Lord Bolingbroke, now settled again in England, endeavoured to divert the thoughts of his friend by inducing him to pass some time in his house, but in about a year after the stroke, Dr. Taylor died of decline (in London, we suppose), December 29, 1731, and was buried in the churchyard of Saint Anne's, Soho. The family estate of Bifrons is still in the possession of the descendants of his brother Herbert.

We shall dismiss other points with brief notice, and as well known, in order to come to the history of *the* theorem: such are the celebrity of Taylor's solution of the problem of vibrating chords, the questions he proposed to the foreign mathematicians in the war of problems, his answer to those of Leibnitz, the accusation of plagiarism made against him by John Bernoulli, and his reply. With reference to the celebrated works on perspective, the first was mathematical, the second intended for artists who hardly knew anything of geometry. Bernoulli charged Taylor with having taken his method from another, and Prony states that it is in fact the one given by Guido Ubaldi, though he thinks Taylor could not have seen that method. The work referred to is 'Guidi Ubaldi Perspectivæ Libri Sex,' Pisauri, 1600, at which we have looked in consequence. Nothing is more easy than assertion about old books: if Prony had really looked attentively at the works of Ubaldi and of Taylor together, he would have seen that whereas the former† only introduced the use of vanishing points as to lines which are horizontal (the picture being vertical), Taylor introduced the method of vanishing points for all lines whatsoever, and made them of universal application. We cannot think that he had never seen Ubaldi's work: a man of learning, an artist from early youth, was not likely to be ignorant of so celebrated a production. He must have seen, and generalized, the method given by Ubaldi. If indeed any one between the two is asserted to have a claim, that claim, when proposed, must be discussed: but a general charge of plagiarism from John Bernoulli is literally no more than a record of the fact that

* Fontenelle, in his Eloge of Malebranche, says that the 'Recherche de la Vérité' was translated into English by a relative of Taylor of the same name.

† The very title page of Ubaldi's work announces by a diagram that its distinctive feature is the use of vanishing points all at the height of the eye.

the party accused and John Bernoulli had had a quarrel, while what relates to Ubaldi is only so far true in that Ubaldi used the particular and Taylor the general method. It is not credible that Ubaldi was ignorant of the general proposition, or if he were so, Stevinus (whose *Sciagraphia* was published in 1608) was not;* but Stevinus did not *use* any vanishing points, except those of lines parallel to the ground, nor Ubaldi neither: while Taylor did *use* them, which is the distinctive feature of his system. Again, it is a strong presumption in favour of Taylor's originality in this point, that works published abroad shortly after his time do not contain it. For example, the 'Kurzgefasste Einleitung zur Perspectiv, von J. C. Bischoff, 1741,' a quarter of a century after the time of Taylor's publication, contains no use of vanishing points except at the height of the eye.

The *Methodus Incrementorum* is the first treatise in which what is at this day called the calculus of finite differences is proposed for consideration. Besides what are now the most common theorems in this subject, there are various purely fluxional or infinitesimal theories, such as the change of the independent variable, integrations, J. Bernoulli's series, &c., and various applications to interpolation, the vibrating chord, the catenary, dome, &c., centre of oscillation and percussion, law of density of the atmosphere, refraction of light. The first enunciation of the celebrated theorem is as follows:—

PROP. VII. THEOR. III.

Sint x et z quantitates duæ variabiles, quarum z uniformiter augetur per data incrementa z, et sit $nz=v$, $v-z=\,'v$, $'v-z=\,''v$, et sic porrò. Tum dico quod quo tempore z creseendo fit $z+v$, x item creseendo fiet

$$x+x\frac{v}{1z}+x\frac{v\,'v}{1.2z^2}+x\frac{v\,'v\,''v}{1.2.3z^3}+, \text{ \&c.}$$

Corollary I. expresses the corresponding theorem for decrements.

COROLL. II.

Si pro Incrementis evanescentibus scribantur fluxiones ipsis proportionales, factis jam omnibus $''v$, $'v$, v, $\dot{v}$, $\ddot{v}$, &c. æqualibus quo tempore z uniformiter fluendo fit $z+v$ fiet x,

$$x+x\frac{\dot{v}}{1z}+x\frac{\ddot{v}^2}{1.2z^2}+x\frac{\dddot{v}^3}{1.2.3z^3}+ \text{ \&c.}$$

vel mutato signo ipsius v, quo tempore z decreseendo fiet $z-v$, x decreseendo fiet

$$x-x\frac{\dot{v}}{1z}+x\frac{\ddot{v}^2}{1.2z^2}-x\frac{\dddot{v}^3}{1.2.3z^3}+, \text{ \&c.}$$

Taylor does not make much use of his own theorem in the *Methodus Incrementorum*, but he shows his command over it in the paper above cited on the roots of equations, in which he extends Newton's method to other than algebraical equations.

One would have supposed that such a theorem as that of Taylor, the instant it was proposed, would have been hailed as the best and most useful of generalizations. Instead of this, it sunk, or rather never rose, till Lagrange pointed out its power. This is perhaps an assertion which some may doubt: we proceed to make it good. The first criticism upon the whole work (without a word about the theorem) was that of Leibnitz, in a letter to John Bernoulli (June, 1716, vol. ii., p. 380, of their correspondence), and it will show of what sort of view the neglect of this theorem was the consequence. The translation is as follows:—'I have received what Taylor calls his Method of Increments. It is an application of the differential and calculus to *numbers, or rather to general mag-*ran in a w[illegible] Thus the English have placed the horses, accord-[illegible] the proverb, behind the cart. I began the diffe-of e[illegible] calculus from series of numbers .... and so came inte[illegible]ly from the general calculus to the special geome-nitur[illegible] or infinitesimal calculus. They proceed the other ing to [illegible]ause they have not the true method of investiga-rential [illegible]. It is written obscurely enough.' Bernoulli an-natural[illegible]rical [illegible]graphia, prop. iii.: 'Si adumbrandæ parallelæ rectæ per vitreum pl[illegible] parallelum conspiciantur, filarum umbræ continuatæ concurrent in way; bo[illegible] puncto radii adumbrandis rectis parallelis: et si adumbrandæ pavimento tion, [illegible]lelæ sint, punctum concursus eadem altitudine supra pavimentum extat [illegible]ulus.'

swers (August, 1716, p. 389):—'I have at length received Taylor's book. What, in the name of God, does the man mean by the darkness in which he involves the clearest things? No doubt to conceal his habit of thieving; as far as I can make it out, I see nothing but what he has stolen from me, through his thick cloud of obscurity.' The notion of Leibnitz prevailed for a long time, and is not quite extinct in our own day, though rapidly expiring: the Differential Calculus was to be used only as the medium in which pure algebra was to be applied to geometry and physics, and even a generalization of existing theorems, expressed in the language of that Calculus, was a positively erroneous mode of proceeding.

In Britain, two really great disciples of Taylor soon appeared, STIRLING and MACLAURIN. The first (*Meth. Diff.*, p. 102) repeated the theorem as given by Taylor himself, and adds that Herman had also given it in the Appendix to his *Phoronomia*; and as this last work was published in 1716, were Stirling's assertion true, Herman must probably be considered an independent inventor. But on examining the appendix to the *Phoronomia* (p. 393), to which Stirling refers, we find only the theorem in book v., lemma 3, of the Principia, and John Bernoulli's series for integration. Maclaurin (*Fluxions*, 1742, p. 610) proved Taylor's theorem again in the way which has since become common. But both Stirling and Maclaurin use only a particular case of Taylor's theorem, expanding not $\phi(x+z)$, but $\phi(0+z)$, or expanding ϕz in powers of z. Neither thought he was doing more than proving Taylor's theorem, and both attribute the result to Taylor. Nevertheless this particular case has been since called Maclaurin's theorem, though, if not Taylor's, it is Stirling's. Maclaurin's book was, no doubt, more read than either of the other two; it was the answer to Berkeley's metaphysical objections, and contained great power and vast store of instances; and this may have been the reason why a theorem which was best used in, and best known by, Maclaurin's book, should be called after his name. It is well that it should be so, or rather, it would be well that the development of $\phi(0+z)$ in powers of z should be called by the name of Stirling: for in truth the development of $\phi(a+b)$ in powers of b is one theorem or another in its uses, and in the consequences it suggests, according as a or b is looked at as the principal letter.

In the interval between Taylor's death and Lagrange's paper in the Berlin Memoirs for 1772, in which he first proposed to make Taylor's theorem the foundation of the Differential Calculus, the theorem was hardly known, and even when known, not known as Taylor's. We cannot find it in Hodgson's Fluxions (1736), in Maria Agnesi's Institutions (1748), in Landen's Residual Analysis (1764), in Simpson's Fluxions (1737), in Emerson's Increments 1763), in Emerson's Fluxions (1743), in Stone's Mathematical Dictionary (1743), nor in the first edition of Montucla's History (1758). We have examined various other places in which it should be, without finding it anywhere, except in the great French Encyclopædia (article 'Series'), and there we certainly did find it, mentioned only incidentally, and attributed by no less a person than Condorcet to D'Alembert. The Abbé BOSSUT, who wrote the preliminary essay, knew nothing about the theorem at that time; though afterwards, when he published his history of mathematics, he was better informed. We found afterwards that Condorcet (Lacroix, tom. iii., p. 396) was in the habit of assigning this theorem to D'Alembert; not with any unfair intention, but in pure ignorance. The fact was that D'Alembert (*Recherches sur différens points* &c., vol. i., p. 50, according to Lacroix) gave for the first time the theorem accompanied by a method of finding the remnant of Taylor's series after a certain number of terms have been taken; and Condorcet, who probably had never seen the theorem elsewhere, thought it was D'Alembert's. In fact, D'Alembert himself gave the theorem as if it were new, and without mentioning the name of any one, which Lacroix says is 'assez singulier,' an opinion in which we cannot agree. Unless D'Alembert read English, we cannot imagine how he should have known Taylor's theorem, nor even then, unless Taylor, Stirling, Maclaurin, or an old volume of the Philosophical Transactions, be supposed to have fallen in his way. We have no doubt that D'Alembert was a new discoverer of the theorem, and that Condorcet never saw it except in his writings. Our wonder rather is where Lagrange could have found the name of Taylor in

connexion with it. For the use which Lagrange proposed to make of it, see DIFFERENTIAL CALCULUS, and FUNCTIONS, THEORY OF. From the time of the publication of the works cited in the article last referred to, Taylor's theorem takes that place which, if it had always occupied, we should not have had to write any history of it. Full justice is done to the discoverer: it only remains to restore to Stirling the view of the theorem which has hitherto been given to Maclaurin.

TAYLOR'S THEOREM. We propose in this part of the article to give some account of the methods of algebraical development which are consequences of the celebrated theorem, the history of which is given in the last article. The simplest parts of the Differential and Integral Calculus will be presumed known. It is not usual in works on that subject to bring together in one place the most conspicuous theorems which have arisen out of that of Taylor; which makes it the more desirable that such a thing should be done in a work of reference. It is to be particularly remembered that we do not here profess to teach the subject of development, but only to recall the steps of the several processes to those who have already learnt them, and to present the theorems in a form which can be easily referred to.

As to notation, we shall frequently signify differentiation by accents: thus $\phi''x$ is the second differential coefficient of ϕx with respect to x; $(\phi x \psi x)'''$ is the third differential coefficient of the product of ϕx and ψx. And $[n]$ will signify the product $1\times2\times3\times\ldots\times(n-1)\times n$. Moreover when a series is written, three terms will be written down, and the general term appended.

Taylor's theorem is as follows:—

$$\phi(x+h)=\phi x+\phi' x.h+\phi'' x\frac{h^2}{2}+\&c.\quad\left\{\phi^{(n)}x\,\frac{h^n}{[n]}\right\}$$

This theorem is true whenever x has such a value that—1. No one of the set ϕx, $\phi' x$, &c. is infinite. 2. All of them do not vanish. Thus neither of the following could be allowed to be treated by it when $x=a$:

$$\sqrt{(x^2-a^2)}\,.\,\log x \quad\text{and}\quad \epsilon^{-(x-a)^{-1}}.$$

In the first function, $\phi' x$, and all which follow, are infinite when $x=a$; in the second ϕx and all its differential coefficients vanish when $x=a$. The meaning of this circumstance is as follows: the form of Taylor's theorem essentially requires that $\phi(x+h)$ should be developed in ascending integer powers of h; consequently when such form of development is impossible, this theorem must show signs of being inapplicable. Now, the first of these functions (when $x=a$) can only have $\phi(a+h)$ expanded in ascending fractional powers; and the second only in descending integer powers. Those who will only allow the use of converging series may require also that h should be so small that the resulting series is convergent: but this objection will afterwards be inapplicable, as will be seen.

We shall state five proofs of this theorem briefly, being substantially those given by Taylor, Maclaurin, D'Alembert, Lagrange, and Ampère.

Taylor's Proof.—Let $n\theta=h$, and form differences of ϕx from the series ϕx, $\phi(x+\theta)$, $\phi(x+2\theta)$, $\ldots$. $\phi(x+n\theta)$. Consequently we have [DIFFERENCE]

$$\phi(x+n\Delta x)=\phi x+n\,\Delta\phi x+n\,\frac{n-1}{2}\Delta^2\phi x+,\ \&c.:$$

where $\Delta x=\theta$. Throw this into the form

$$\phi(x+h)=\phi x+\frac{\Delta\phi x}{\Delta x}h+\frac{\Delta^2\phi x}{(\Delta x)^2}h\,\frac{h-\Delta x}{2}+,\ \&c.$$

Let n increase without limit, Δx at the same time diminishing, so that $n\Delta x$ remains always $=h$. Then

$$\phi(x+h)=\phi x+\left(\begin{matrix}\text{Limit of}\\ \Delta\phi x:\Delta x\end{matrix}\right)h+$$

$$\left(\begin{matrix}\text{Limit of}\\ \Delta^2\phi x:(\Delta x)^2\end{matrix}\right)\frac{h^2}{2}+,\ \&c.$$

So that Taylor's theorem is proved when we know that $\phi^{(h)}x$ is the same as the limit of $\Delta^h\phi x:(\Delta x)^h$. This was an assumption* of Taylor's: but in the modern differential calculus it is a better plan to prove Taylor's theorem in another way, and then from the preceding follows the simplest manner of showing the identity of $\phi^{(h)}x$ and the limit of $\Delta^h\phi x:(\Delta x)^h$.

Maclaurin's Proof.—The method here given was first used by Maclaurin, and though it was only applied to develop $\phi(0+h)$, yet it will do equally well for $\phi(x+h)$; and Maclaurin himself saw no difference (as indeed there is none, ϕ being any function whatever) between the two cases. It turns upon $\phi(x+h)$ giving the same result, whether differentiated with respect to x or h, and assumes the form of the development, which is a radical defect. It is as follows: Let $\phi(x+h)=A+Bh+Ch^2+$, &c.; then $\phi'(x+h)=B+2Ch+3Dh^2+$, &c., $\phi''(x+h)=2C+3.2Dh+$, &c., $\phi'''(x+h)=3.2D+$, &c., which, when $h=0$, give $\phi x=A$, $\phi' x=B$, $\phi'' x=2C$, $\phi''' x=3.2D$, &c.; from which the theorem readily follows. The common proof, given in most elementary works on the differential calculus, is but a less commodious form of this.

D'Alembert's Proof.—The first principles of the Integral Calculus give

$$\phi(a+h)=\phi a+\int_a^{a+h}\phi' x\,dx.$$

Let $x=a+h-z$; $\int_a^{a+h}\phi' x\,dx=-\int_h^0\phi'(a+h-z)dz$

$$=\int_0^h\phi'(a+h-z)dz=\phi' a.h+\int_0^h\phi''(a+h-z).z\,dz;$$

the last step being made by parts. Similarly

$$\int_0^h\phi''(a+h-z)z\,dz=\phi'' a\frac{h^2}{2}+\int_0^h\phi'''(a+h-z)\frac{z^2dz}{2}$$

$$\int_0^h\phi'''(a+h-z)\frac{z^2dz}{2}=\phi''' a\frac{h^3}{2.3}+\int_0^h\phi^{\text{iv}}(a+h-z)\frac{z^3dz}{2.3}$$

and so on: whence it appears that if we go up to h^n in the series, the term involving h^n may be followed by another, expressed in the form of a definite integral, and which alone represents all the remnant of the series; as follows:—

$$\phi^{(n)}a\,\frac{h^n}{[n]}+\frac{1}{[n]}\int_0^h\phi^{(n+1)}(a+h-z).z^n\,dz.$$

The conditions of integration require that neither ϕx, $\phi' x$, $\ldots$. $\phi^{(n+1)}x$ should be infinite from $x=a$ to $x=a+h$, both inclusive: this one condition being satisfied, the difficulty of divergent series disappears; for the theorem does not give an infinite series at all, but only any number we please of the terms of a series together with a concluding quantity which is finite both in form and reality. This integral might frequently be difficult to use, but limits for its value may be readily obtained. Let P and p be the greatest and least values of $\phi^{(n+1)}x$ from $x=a$ to $x=a+h$, both inclusive: then the concluding integral lies between

$$P\int_0^h z^n dz \text{ and } p\int_0^h z^n dz \text{ or } \frac{Ph^{n+1}}{n+1} \text{ and } \frac{ph^{n+1}}{n+1}.$$

Now when a continuous function does not become infinite between two values of x, every quantity which lies between its greatest and least value is one of its intermediate values: or anything between P and p is a value of $\phi^{(n+1)}(a+\theta h)$, for some value of θ which is either 0 or 1, or between them. Hence the preceding expression may be written

$$\phi^{(n)}a\,\frac{h^n}{[n]}+\phi^{(n+1)}(a+\theta h)\frac{h^{n+1}}{[n+1]}.$$

The following form has been given by M. Cauchy. Let P and p represent the greatest and least values of $\phi^{(n+1)}(a+h-z).z^n$ from $z=0$ to $z=h$, both inclusive: precisely similar reasoning will give for the last term chosen of Taylor's series, and the value of the remnant,

$$\phi^{(n)}a\,\frac{h^n}{[n]}+\phi^{(n+1)}(a+h-\theta h).\theta^n\,\frac{h^{n+1}}{[n]}$$

where θ is either 0 or 1, or between them.

* 'Si pro incrementis evanescentibus scribantur fluxiones ipsis proportionales, &c.' See the statement in TAYLOR, BROOK.

We call the preceding D'Alembert's proof, but it is rather D'Alembert's result, and even that in a different form: his real process is as follows:—To take a case, integrate $\phi^{iv}(x+h)$ four times with respect to h, beginning at $h=0$: the results are ($x+h=X$ for abbreviation)

$$\phi'''X-\phi'''x=\int dh\,.\,\phi^{iv}X$$

$$\phi''X-\phi''x-\phi'''x\,.\,h=\left(\int dh\right)^2\phi^{iv}X$$

$$\phi'X-\phi'x-\phi''x\,.\,h-\phi'''x\,\frac{h^2}{2}=\left(\int dh\right)^3\phi^{iv}X$$

$$\phi X-\phi x-\phi'x\,.\,h-\phi''x\,\frac{h^2}{2}-\phi'''x\,\frac{h^3}{2.3}=\left(\int dh\right)^4\phi^{iv}X,$$

and from this sort of process the result is

$$\phi(x+h)=\phi x+\phi'x\,.\,h+\phi''x\,\frac{h^2}{2}+\ldots.$$

$$+\phi^{(n)}x\,\frac{h^n}{[n]}+\left(\int_0^h dh\right)^n\phi^{(n)}(x+h),$$

the two sides presenting the most identical forms which have yet occurred. The integral may easily be reduced to the form already given (Lacroix, vol. iii., p. 397). D'Alembert finished with the preceding form: it was Lagrange who first gave the limits which we have appended above.

Lagrange's Proof.—By this we do not mean the fallacious proof referred to in FUNCTIONS, THEORY OF, but that by which Lagrange established the limits of the value of the remnant, which, on the ordinary definition of a differential coefficient, is a proof, and a very satisfactory one, of the whole theorem. It rests upon the proposition that if a function of x have always one sign from $x=a$ to $x=a+h$, the integral of that function taken between those limits will have the same sign.

If then we wish to establish Taylor's theorem as far as, say, the term involving h^3, and to give the limits of the remainder, let P and p be the greatest and least values of $\phi^{iv}(a+z)$ from $z=0$ to $z=h$. Between those limits then $\phi^{iv}(a+z)-P$ is negative: integrate from $z=0$ to $z=$ any value not greater than h, and, by the preliminary theorem, $\phi'''(a+z)-\phi'''a-Pz$ is negative. Integrate successively under the same conditions, and we learn, step by step, that

$$\phi''(a+z)-\phi''a-\phi'''a\,.\,z-P\,\frac{z^2}{2}$$

$$\phi'(a+z)-\phi'a-\phi''a\,.\,z-\phi'''a\,\frac{z^2}{2}-P\,\frac{z^3}{2.3}$$

$$\phi(a+z)-\phi a-\phi'a\,.\,z-\phi''a\,\frac{z^2}{2}-\phi'''a\,\frac{z^3}{2.3}-P\,\frac{z^4}{2.3.4}$$

are severally negative. But $\phi^{iv}x-p$ is positive from $x=a$ to $x=a+h$; consequently, proceeding in the same manner, we find that, z being not greater than h,

$$\phi(a+z)-\phi a-\phi'a\,.\,z-\phi''a\,\frac{z^2}{2}-\phi'''a\,\frac{z^3}{2.3}-p\,\frac{z^4}{2.3.4}$$

is positive. If then we make $z=h$, we find that $\phi(a+h)$ lies between

$$\phi a+\phi'a\,.\,h+\ldots.+P\,\frac{h^4}{2.3.4}\text{ and }\phi a+\phi'a\,.\,h+\ldots+p\,\frac{h^4}{2.3.4},$$

and the rest is as in the last proof.

There is a proof given by M. Cauchy which resembles the preceding in its principle, though of very different details, which may be seen in the *Lib. U. K.*, Differential Calculus, pp. 68, &c., 767. But this proof, though very well in a treatise on the subject, on account of the collateral uses of the preliminary theorems which it requires, is not so well suited to an isolated article on Taylor's theorem.

Ampère's Proof.—Let $\phi x=\phi a+P(x-a)$; differentiate successively with respect to a, and we have

$$0=\phi'a+P'(x-a)-P$$
$$0=\phi''a+P''(x-a)-2P'$$
$$0=\phi'''a+P'''(x-a)-3P'', \text{ &c.,}$$

substitute for P, P′, &c. their values: that is, substitute from each equation to the preceding, and we have, making $x=a+h$, Taylor's theorem with the following result for the remnant following the term which has h^n in it

$$\frac{d^n}{da^n}\left(\frac{\phi x-\phi a}{x-a}\right)\frac{h^{n+1}}{[n]},$$

making $x=a+h$ after differentiation.

It gives some trouble to show the limits of this expression, for which we may refer to Ampère, 'Précis de Calcul Différentiel,' &c., Journ. Ec. Polytechn., cah. xiii., p. 120. This tract of Ampère is one of the purest deductions extant of the Differential Calculus from the theory of limits.

In looking through all the proofs which give limits to the remnant of the series, it will be seen that neither ϕx nor any differential coefficient employed can be allowed to become infinite between $x=a$ and $x=a+h$. When such a circumstance does occur, the theorem relative to the limits may cease to be true. For instance, let $\phi x=(x-m)^{-1}$, and stop the series after the first term, which gives

$$\frac{1}{a+h-m}=\frac{1}{a-m}-\frac{1}{(a+\theta h-m)^2}\,.\,h$$

if $a+h$ and a be both greater or both less than m, a value of θ lying between 0 and 1 will be found to satisfy this equation, as it should do from the theorem. But if $x=m$ between $x=a$ and $x=a+h$, none but an imaginary value of θ will satisfy this equation.

Stirling's theorem, as it should be called, Maclaurin's as it is called, is found simply by making $a=0$ in the development of $\phi(a+x)$. It gives

$$\phi x=\phi 0+\phi'0.x+\phi''0\,\frac{x^2}{2}+\ldots..$$

$$+\phi^{(n)}0\,\frac{x^n}{[n]}+\phi^{(n+1)}(\theta x)\,\frac{x^{n+1}}{[n+1]}$$

θ being either 0 or 1, or between them. Here $\phi^{(n)}0$ means that ϕx is to be differentiated n times, and x made $=0$ *after all the differentiations*. This is the most useful form of Taylor's theorem, with which it may be considered as identical in one point of view, and of which it is a particular case in another: for $\psi(a+x)$ absolutely developed by Stirling's theorem is simply $\psi(a+x)$ developed from ψa by Taylor's theorem.

John Bernoulli's theorem, as given in the Leipsic acts for 1696, is as follows:—

$$\int_0^x\psi x\,dx=\psi x.\,x-\psi'x\,.\,\frac{x^2}{2}+\psi''x\,\frac{x^3}{2.3}-\text{ &c.}$$

Here is an instance very much resembling the connexion of the BINOMIAL THEOREM (p. 412) with Wallis's previous investigations. If Wallis had looked at his own result in a new point of view, he might not have left the binomial theorem for Newton: if John Bernoulli had done the same, he might have given the law of development of $\phi(x+h)$. The preceding is a case of Taylor's theorem, as follows: by that theorem

$$\phi(x-x)=\phi x-\phi'x\,.\,x+\phi''x\,\frac{x^2}{2}-\ldots.$$

$$\pm\phi^{(n)}x\,\frac{x^n}{[n]}\mp\phi^{(n+1)}(x-\theta x)\,.\,\frac{x^{n+1}}{[n+1]}$$

and $x-\theta x$ is the same in meaning as θx, an undetermined fractional part of x. Let $\phi x=\int_0^x\psi x\,dx$, then $\phi 0=0$, and substitution and transposition give

$$\int_0^x\psi x\,dx=\psi x.\,x-\psi'x\,\frac{x^2}{2}+\psi''x\,\frac{x^3}{2.3}$$

$$\pm\psi^{(n-1)}x\,\frac{x^n}{[n]}\mp\psi^{(n)}(\theta x)\,\frac{x^{n+1}}{[n+1]}$$

This theorem is not of much use as a method of development, so that we need say no more of it in the present article.

Some views of Lambert on the reduction of the roots of equations (*Acta Helvetica*, 1758) into series were generalized by Lagrange (*Mém. Acad. Sci.*, 1768) into a celebrated theorem of development bearing his name; and this again was generalized in form by Laplace (*Méc. Cél.*).

The problem is as follows: given

$$y=\mathrm{F}(z+x\phi y) \ldots . \text{(A)}$$

required the expansion of ψy, when possible, in powers of x. Since ψy is, by the preceding equation, a function of x and z, if z be constant, and we differentiate with respect to x, and then make $x=0$, or $y=\mathrm{F}z$, we may use Stirling's theorem. But this differentiation would be laborious and indirect; it was made more direct (by Laplace) in the following manner:—A constant may have any value given to it, or may be made to vanish, either before or after differentiation with respect to a variable: if then we can express differentiations with respect to x in terms of differentiations with respect to z only (in which x is constant), it will be in our power to make x vanish *before* the differentiations, which will reduce the indirect or implicit to direct differentiation. This substitution of z-differentiations in place of those of x is done as follows:—Differentiate (A) both with respect to x and z separately, and we have

$$\frac{dy}{dx}=\mathrm{F}'(z+x\phi y)\left\{\phi y+x\phi' y\frac{dy}{dx}\right\} \quad \text{whence}$$

$$\frac{dy}{dz}=\mathrm{F}'(z+x\phi y)\left\{1+x\phi' y\frac{dy}{dz}\right\} \quad \frac{dy}{dx}=\phi y\frac{dy}{dz}$$

Let u be a function of y only, that is, not of x or z except as these variables are contained in y: then

$$\frac{du}{dy}\frac{dy}{dx}=\phi y\frac{du}{dy}\frac{dy}{dz} \quad \text{or} \quad \frac{du}{dx}=\phi y\frac{du}{dz}$$

From this equation only it may be shown (by Induction) that

$$\frac{d^n u}{dx^n}=\frac{d^{n-1}}{dz^{n-1}}\left(\overline{\phi y}^n\frac{du}{dz}\right)$$

as follows. Assume the preceding to be true for one value of n, and, since $(\phi y)^n\times du : dy$ is a function of y only, let it be $dv : dy$, v being another function of y.

$$\frac{d^n u}{dx^n}=\frac{d^{n-1}}{dz^{n-1}}\left(\frac{dv}{dy}\frac{dy}{dz}\right)=\frac{d^n v}{dz^n}$$

$$\frac{d^{n+1}u}{dx^{n+1}}=\frac{d^n}{dz^n}\left\{\frac{dv}{dx}, \text{ or } \phi y\frac{dv}{dz}, \text{ or } \phi y\frac{dv}{dy}\frac{dy}{dz}, \text{ or }\right.$$

$$\left.\phi y\,(\phi y)^n\frac{du}{dy}\frac{dy}{dz}, \text{ or } (\phi y)^{n+1}\frac{du}{dz}\right\}$$

whence the theorem remains true after writing $n+1$ for n. But it is true when $n=1$; therefore it is true for all values of n. If then we make $x=0$, or $y=\mathrm{F}z$, which may be done before the differentiations on the second side of the equation, we have (u being ψy)

$$\left\{\frac{d^n\psi y}{dx^n}(x=0)\right\}=\frac{d^{n-1}}{dz^{n-1}}\left\{(\phi\mathrm{F}z)^n\frac{d\psi\mathrm{F}z}{dz}\right\}$$

Apply this to Stirling's Theorem, and we have *Laplace's Theorem*, namely,

$$y=\mathrm{F}(z+x\phi y) \text{ gives } \psi y=$$

$$\psi\mathrm{F}z+\left(\phi\mathrm{F}z\frac{d\psi\mathrm{F}z}{dz}\right)x+\frac{d}{dz}\left((\phi\mathrm{F}z)^2\frac{d\psi\mathrm{F}z}{dz}\right)\frac{x^2}{2}+, \&c.$$

$$\text{the general term, } \frac{d^{n-1}}{dz^{n-1}}\left\{(\phi\mathrm{F}z)^n\frac{d\psi\mathrm{F}z}{dz}\right\}\frac{x^n}{[n]}$$

Lagrange's theorem, from which Laplace generalized, is the case in which $\mathrm{F}x=x$; namely,

$$y=z+x\phi y \text{ gives } \psi y=$$

$$\psi z+(\phi z\psi' z)x+\frac{d}{dz}\left(\overline{\phi z}^2\psi' z\right)\frac{x^2}{2}+, \&c.$$

$$\text{the general term } \frac{d^{n-1}}{dz^{n-1}}\left\{(\phi z)^n\psi' z\right\}\frac{x^n}{[n]}$$

$$y=z+\phi z.x+\frac{d(\phi z)^2}{dz}\frac{x^2}{2}+\frac{d^2(\phi z)^3}{dz^2}\frac{x^3}{2.3}+, \&c.$$

Lagrange's theorem leads to *Burmann's Theorem* (presented to the institute in 1796). The second is in fact the same as the first, though very different in form, and arrived at independently. It is required, when possible, to expand ψx in powers of ϕx. This might be done indirectly, by expanding $\psi\phi^{-1}x$ in powers of x, and substituting ϕx for x in the result. The form in which Burmann obtained Lagrange's theorem avoids the indirect process. Let ϕx vanish when $x=a$, and let $\phi x=(x-a):\chi x$, or $x=a+\phi x.\chi x$. We can now employ Lagrange's theorem to expand ψx in powers of ϕx, and we have

$$\psi x=\psi a+\chi a\psi' a.\phi x+\frac{d}{da}\left(\overline{\chi a}^2\psi' a\right)\frac{(\phi x)^2}{2}+, \&c.$$

Now the general term of this has for its co-efficient the value of

$$\frac{d^{n-1}}{dx^{n-1}}\left((\chi x)^n\psi' x\right) \text{ or } \frac{d^{n-1}}{dx^{n-1}}\left\{\left(\frac{x-a}{\phi x}\right)^n\psi' x\right\}$$

when $x=a$: consequently ψx, expanded in powers of ϕx, is found by making $x=a$ in the co-efficients of the powers of ϕx in the following series:—

$$\phi a+\left\{\frac{x-a}{\phi x}.\psi' x\right\}\phi x+\left\{\frac{d}{dx}\left(\left(\frac{x-a}{\phi x}\right)^2\psi' x\right)\right\}\frac{(\phi x)^2}{2}+, \&c.$$

When in a function of any number of variables x_1, x_2, &c., the variables are severally to receive increments h_1, h_2, &c., the law of the development is best seen by the calculus of operations. [Operation.] To change x into $x+h$ is to perform the operation $\epsilon^{h\mathrm{D}}$, D being the symbol of differentiation with respect to x: the condensed form of the development now before us is

$$\epsilon^{h_1\mathrm{D}_1+h_2\mathrm{D}_2+\ldots.}\,\phi(x_1, x_2, \ldots..)$$

where D_1, D_2, &c. refer to x_1, x_2, &c. The general term of the development is

$$\frac{(h_1\mathrm{D}_1+h_2\mathrm{D}_2+\ldots..)^n}{[n]}\phi(x_1, x_2, \&c.)$$

which must itself be developed. It is not worth while to pursue this case further; we shall only observe that when it is desired to stop, the remnant may be obtained by writing in the last term $x_1+\theta h_1$ for x_1, $x_2+\theta h_2$ for x_2, &c., where θ, the same in all, is either 0 or 1, or between them.

The value of x which makes $\phi x=0$ is represented by

$$a-\frac{\phi}{\phi'}-\frac{\phi''\phi^2}{2\phi'^3}-\frac{(3\phi''^2-\phi'\phi''')\phi^3}{2.3\phi'^5}$$

$$-\frac{(15\phi''^3-10\phi'\phi''\phi'''+\phi'^2\phi^{\mathrm{iv}})\phi^4}{2.3.4\phi'^7}$$

$$-\frac{\{105\phi''^4(\phi''^2-\phi'\phi''')+10\phi'^2\phi''^2+15\phi'^2\phi''\phi^{\mathrm{iv}}-\phi'^3\phi^{\mathrm{v}}\}\phi^5}{2.3.4.5\phi'^9}$$

– &c.: where a is any assumed value (the nearer the root the better) and ϕ, ϕ', &c. represent ϕa, $\phi' a$, &c. This series is obtained by common reversion from $\phi(a+h)=0$. For the forms which Paoli gave to this series, and also to Burmann's, see Lacroix, vol. i., pp. 306-308. The preceding series has been used, as far as three terms, in the article Approximation.

All that precedes is found in elementary treatises, with the exception of a few terms of the last series: we now come to matter which has been hitherto only the property of the well-read mathematician, but which well deserves to be made as common as Taylor's Theorem. We refer to Arbogast's *method of derivations*. Few, even among mathematicians, are aware of the power of this process, which may perhaps arise from their taking Lacroix's account of it, instead of consulting the work of Arbogast himself: the former has only exhibited it to show that it may be reduced to processes of the differential calculus; and even the latter has so loaded his method with heavy applications, that he has concealed much of its beauty and simplicity.

The foundation of Arbogast's methods is a contrivance for expediting the expansion of $\phi(a+bx+cx^2+\ldots.)$ into a series of the form $\mathrm{A}+\mathrm{B}x+\mathrm{C}x^2+\ldots.$ The process by which B is formed from A, C from B, &c. is uniform, and is called derivation; and A being ϕa, B may be called $\mathrm{D}\phi a$, C may be called $\mathrm{DD}\phi a$. or $\mathrm{D}^2\phi a$, and so on. Hence b ought to be called $\mathrm{D}a$, C ought to be $\mathrm{D}^2 a$, and so on. This notation is not precisely that of Arbogast, but will do for our purpose. For more detail,* see the Differential Calculus (*Library of Useful Knowledge*), pp. 328-334.

* There is a great deal on the subject in the 'Mathematical Treatises' (posthumous) of the Rev. John West, published at Edinburgh in 1808. Mr. West

If, for a moment, we write the expansion thus—

$$\phi(a_0+a_1x+a_2x^2+\&c.) = A_0+A_1x+A_2x^2+\&c.;$$

and if we differentiate both sides with respect to a_m, x and all the other coefficients remaining constant, we have

$$\phi'(a_0+a_1x+\&c.)\,.\,x^m = \frac{dA_0}{da_m} + \frac{dA_1}{da_m}x +, \&c.$$

which shows that a_m cannot enter any coefficient preceding A_m, or

$$\phi'(a_0+a_1x+\&c.) = \frac{dA_m}{da_m} + \frac{dA_{m+1}}{da_m}x +, \&c.$$

The first side of this is the same series, whatever letter a_m was made to vary; the second side is therefore always the same series; whence we collect that $dA_{m+n} : da_m$ does not alter with the value of m, being always the coefficient of x^n in the development of $\phi'(a_0+a_1x+, \&c.)$. It is enough to satisfy this condition for each letter and its preceding one; that is to say, each co-efficient differentiated with respect to any one letter, is to yield the same result as the directly preceding co-efficient differentiated with respect to the directly preceding letter. The following rules are found sufficient. To pass from any one derivative of ϕa to the next, arrange the letters a, b, c, &c., or a_0, a_1, a_2, &c., whichever may be used, in order, in every term: differentiate with respect to the last letter in each term, and multiply by the letter which comes next to it. And when the last but one immediately precedes the last in the alphabet or other consecutive system, do the same with the last but one, and divide by the exponent of the last letter, as it becomes after the increase which it receives from the process of the preceding letter; but in no case use any letters but the last or the last but one. For instance, beginning with ϕa, in which is only one letter, we have $\phi'a\,.\,b$, or

$$\mathrm{D}\phi a = \phi'a\,.\,b;$$

in which are two letters, a and b, consecutive. Operate upon b, and we have $\phi'a\,.\,c$; operate on $\phi'a$, and we have again $\phi''a\,.\,b$, which, with the b which was in before, is $\phi''a\,.\,b^2$, which we divide by the new exponent of b, or by 2, whence

$$\mathrm{D}^2\phi a = \phi'a\,.\,c + \frac{\phi''a}{2}b^2.$$

In forming $\mathrm{D}^3\phi a$, we use only c in $\phi'a\,.\,c$, because a does not immediately precede c; and we get (the succession being a, b, c, e, f, g, h, k, &c.)

$$\mathrm{D}^3\phi a = \phi'a\,.\,e + \frac{\phi''a}{2}\,.2bc + \frac{\phi'''a}{2.3}b^3;$$

and so on. As soon however as the law is established, it is best to form a table of the successive derivatives of the powers of b by this same law: we then have

$$\mathrm{D}^n\phi a = \phi'a\mathrm{D}^{n-1}b + \frac{\phi''a}{2}\mathrm{D}^{n-2}b^2 + \frac{\phi'''a}{2.3}\mathrm{D}^{n-3}b^3 + \&c.$$

as far as $\dfrac{\phi^n a}{[n]}\,b^n$;

in which $\phi'a$, $\phi''a$, &c. are to be taken from the function by common differentiation, and the derivatives of the powers of b from the table. This being done, we have

$$\phi(a+bx+cx^2+cx^3+fx^4+gx^5+, \&c.) = \phi a + \mathrm{D}\phi a\,.\,x + \mathrm{D}^2\phi a\,.\,x^2 + \mathrm{D}^3\phi a\,.\,x^3 +, \&c.;$$

and the process is shortened to its utmost extent; all that is not differentiation being merely reference to a table and writing the result.

We shall give materials for proceeding as far as the term $\mathrm{D}^{12}\phi a\,.\,x^{12}$, not that so much will often be necessary, but because it is desirable to show with how little trouble questions of enormous labour in the ordinary way, such, for instance, as that solved in Reversion of Series, may be looked at without dismay. We have to form every derivative of every power of b, $\mathrm{D}^m b^n$, in which $m+n$ does not exceed 12.

has substituted a notation, for that of Arbogast, in which he will probably have few followers. The student who is not repelled by this, and cannot procure Arbogast's work, will find West's treatises abounding in derivations.

$\mathrm{D}b^9=9b^8c$
$\mathrm{D}^2b^9=9b^8e+36b^7c^2$
$\mathrm{D}^3b^9=9b^8f+72b^7ce+84b^6c^3$

$\mathrm{D}b^{10}=10b^9c$ $\mathrm{D}^2b^{10}=10b^9e+45b^8c^2$

$\mathrm{D}b^{11}=11b^{10}c$

To verify these results, observe that if we consider each letter as of the first dimension, every term of $D^n b^r$ is of the rth dimension; but if we consider each letter as of the dimension following:—

b	c	e	f	g	h	k	l	m	n	p	q
1	2	3	4	5	6	7	8	9	10	11	12:

then every term of $D^n b^r$ is of the $(n+r)$th dimension. To find out if all the proper terms be there, and with the proper exponents, write down the number of ways in which $n+r$ can be made out of r numbers. Thus to verify this point for $D^7 b^3$, write down the ways in which 10 can be made out of three numbers, namely,

8+1+1, 7+2+1, 6+3+1, 6+2+2, 5+4+1, 5+3+2, 4+4+2, 4+3+3;

take the letter answering to each number, in the above list, and multiply the letters of each set together, which gives

$$b^2l,\ bck,\ beh,\ c^2h,\ bfg,\ ceg,\ cf^2,\ e^2f,\ .$$

which are, coefficients excepted, the terms of $D^7 b^3$ in the table. To verify the coefficients separately, observe that the coefficient of that term of $D^n b^r$ which contains the sth power, tth power, &c., is

$$\frac{1.2.3.\ldots.\ (r-1)r}{1.2.3\ldots s\times 1.2.3\ldots t\times\ldots\ldots}.$$

Thus in $D^4 b^8$, the term containing b^5c^2e ought to be multiplied by

$$\frac{1.2.3.4.5.6.7.8}{1.2.3.4.5\times 1.2\times 1}, \text{ or } 168, \text{ as is the case.}$$

But the best general mode of verification is derived from the theorem

$$D^n b^{r-1} = \frac{1}{r}\frac{dD^n b^r}{db}, \text{ or } D^{n+1} b^{r-1} = \frac{1}{r} D\left(\frac{dD^n b^r}{db}\right);$$

that is, having a certain derivative of a certain power, the next higher derivative of the next lower power may be found by differentiating with respect to b, dividing by the exponent of the original power, and then performing the derivation. Thus:

$$D^3 b^9 = 9b^8 f + 72b^7 ce + 84b^6 c^3,$$

differentiate with respect to b, and divide by 9, which gives

$$8b^7 f + 56b^6 ee + 56b^5 c^3.$$

Now derive, which gives

$$8b^7 g + 56b^6 cf + 28b^5 e^2 + 168b^5 c^2 e + 70b^4 c^4,$$

the same as is found in the table for $D^{3+1} b^{9-1}$. Here we verify the earlier result of the table from the later: to verify the later from the earlier, use the following:—

$$D^n b^r = D^{n-1} c.r b^{r-1} + D^{n-2} c^2.r\frac{r-1}{2} b^{r-2} +, \text{ &c.}$$

$$\text{up to } c^n \frac{r(r-1)\ldots\ (r-n+1)}{1.2\ \ldots\ n} b^{r-n}, \ldots$$

in which the derivatives of powers of c must be formed from the corresponding tabular ones of b, by changing each letter into the next following. There are thus abundant means of verification. We will mention yet one method more. Only the last letter and the last but one (and that only when the two letters are consecutive) are used in the derivations. If we use any letter, no new term is produced, but only a repetition of those which other terms give. For instance, in $D^6 b^5$ is the term $60b^5cef$; and in passing to $D^7 b^5$, we derive from f because it is the last letter; and from e because, being the last but one, it immediately precedes f in the series. We do not here use b and c at all; but if we did use them, we should only repeat terms which will come into $D^7 b^5$ from other sources. Thus:—$60b^5cef$ gives, from f, $60b^5ceg$, which is set down in $D^7 b^5$: from e, $60b^5cff \div 2$, or $30b^5cf^2$, which is also set down: from c, if c had been used, we should have had $60b^5eef \div 2$, or $30b^5e^2f$, which, on looking, we find set down, as arising from the last letter of $10b^2e^3$. From b, in $60b^5cef$, had it been used, we should have got $120bccef \div 2$, or $60bc^2ef$, which is also found, and arises from the last letter of $30bc^2e^3$. If then we ever find that derivation from one of the unused letters gives anything but what arises from some of the letters which are used, it is a sign that some error has been committed.

By help of the preceding method, expansions which analysts usually avoid as much as possible, at almost any expense of circumoperation, are carried with the greatest facility even further than is necessary. The development of $\phi(a+bx+cx^2+$ &c.), already given, is one instance; the process in Reversion of Series is another. This last is done* by expanding x in powers of $ax+bx^2+$, &c., by Burmann's Theorem, and making the expansion of the negative powers of $(a+bx+cx^2+$, &c.), which will be wanted, by the method of derivations. We shall state some further applications:—

$$(b+cx+ex^2+\text{ &c.})^m = b^m + Db^m.\ x + D^2 b^m.\ x^2 +, \text{ &c.}$$

When m is integer, these derivatives are in the table. When $b+cx+$ &c. is a finite series, the whole result is brought out with great ease, compared with the trouble of the common algebraical operation: in this case the value of every letter after the last in the finite series is 0, or the last letter of that series is not to be employed in derivation. Let the reader try for himself $(b+cx+ex^2+fx^3)^5$ by this mode and then in the common way, going only so far in the latter as to feel sure that the former is of no trouble compared with it. Let m, $m\frac{m-1}{2}$, &c. be denoted by m, m_2, &c.

$$(a+bx+cx^2+\text{ &c.})^m = a^m + mba^{m-1}x + (mac + m_2 b^2)a^{m-2}x^2 + (ma^2c + m_2 aDb^2 + m_3 b^3)a^{m-3}x^3 + (ma^3 f + m_2 a^2 D^2 b^2 + m_3 aDb^3 + m_4 b^4)a^{m-4}x^4$$

+, &c.; the law of which is evident, the only thing left being the substitution of the values in the tables instead of the derivatives of b. This form is convenient for fractional or negative powers. The following case is worth exhibiting separately:—

$$\frac{1}{a+bx+, \text{ &c.}} = \frac{1}{a} - \frac{b}{a^2}x + \frac{b^2-ac}{a^3}x^2 - \frac{b^3 - aDb^2 + a^2 e}{a^4}x^3 + \frac{b^4 - aDb^3 + a^2D^2b^2 - a^2 f}{a^5}x^4$$

−, &c. We have avoided the formality of writing Db for c, $D^2 b$ for e, &c.

$$\frac{A+Bx+Cx^2+, \text{ &c.}}{a+bx+cx^2+, \text{ &c.}} = \frac{A}{a} - \frac{Ab-Ba}{a^2}x + \frac{A(b^2-ac) - Bab + Ca^2}{a^3}x^2 - \frac{A(b^3 - aDb^2 + a^2 e) - Ba(b^2-ac) + Ca^2 b - Ea^3}{a^4}x^3 +, \text{ &c.}$$

The law is here evident enough; the next numerator would be

$$A(b^4 - aDb^3 + a^2D^2b^2 - a^3 f) - Ba(b^3 - aDb^2 + a^2 e) + Ca^2(b^2 - ac) - Ea^3 b + Fa^4$$

The derivatives of the general term b^n may be readily formed, but the particular cases are more useful; see the derivatives of a^m in the general form above given. We shall not overload this subject with further examples: enough have been given to show those who require developments of some extent how much labour they might save.

It frequently happens that the form given is not

$$\phi(a+bx+cx^2+, \text{ &c.}) \text{ but } \phi\left(a + bx + \frac{cx^2}{2} + \frac{ex^3}{2.3} +, \text{ &c.}\right),$$

in which case the occurrence of the fractions in the denominator renders the process more complicated than it need

* M. Wronski has given elegant forms of transformation and development, which are most accessible in Montferrier's 'Dictionnaire des Sciences Mathématiques,' Paris, 1835. The author of these developments has wrapt himself in a cloud of obscurity, and adopted the tone of an assailant, with not a little of the manner of a charlatan, which has hindered his really remarkable extensions from receiving the notice to which they are entitled, and himself from obtaining the character as a mathematician which no one who reads his works can for a moment deny him. We do not enter into his methods, because, though good in theory, they are not easily used, from their excessive generality. For instance, in the article on Reversion of Series, in the dictionary cited, the author of which is a partizan of M. Wronski, the results are carried as far as I. of our article on that subject, not by the vaunted methods, but by the old method of indeterminate coefficients, an immense labour, after which the name of the undertaker is very properly recorded. To repeat the same process and to carry it two terms further, by Arbogast's and Burmann's methods combined, did not take us three hours.

be. We put down tables for the development of this function, derived from the preceding tables, as far as the tenth power of x: to be used as follows:—

Let

$$\phi\left(a+bx+c\frac{x^2}{2}+e\frac{x^3}{2.3}+\&c.\right)=A_0+A_1x+A_2\frac{x^2}{2}+\&c.$$

Then $A_n=\phi' a\,.\,D^{n-1}b+\phi'' a\,.\,D^{n-2}b^2+\ldots+\phi^{(n)}a\,.\,b^n$

where the derivatives of the powers of b, which do not mean the same as hitherto, are to be taken from the following table:—

$Db=c$

$D^2b=e$, $D\,b^2=3bc$

$D^3b=f$, $D^2b^2=4be+3c^2$, $Db^3=6b^2c$

$D^4b=g$, $D^3b^2=5bf+10ce$, $D^2b^3=10b^2e+15bc^2$, $Db^4=10b^3c$

$D^5b=h$, $D^4b^2=6bg+15cf+10e^2$, $D^3b^3=15b^2f+60bce+15c^3$
$D^2b^4=20b^3e+45b^2c^2$, $Db^5=15b^4c$

$D^6b=k$, $D^5b^2=7bh+21cg+35cf$
$D^4b^3=21b^2g+105bcf+70be^2+105c^2e$
$D^3b^4=35b^3f+210b^2ce+105bc^3$
$D^2b^5=35b^4c+105b^3c^2$, $Db^6=21b^5c$

$D^7b=l$, $D^6b^2=8bk+28ch+56eg+35f^2$
$D^5b^3=28b^2h+168bcg+280bcf+210c^2f+280ce^2$
$D^4b^4=56b^3g+420b^2cf+280b^2e^2+840bc^2e+105c^4$
$D^3b^5=70b^4f+560b^3ce+420b^2c^3$
$D^2b^6=56b^5e+210b^4c^2$, $Db^7=28b^6c$

$D^8b=m$, $D^7b^2=9bl+36ck+84eh+126fg$
$D^6b^3=36b^2k+252bch+504beg+315bf^2+378c^2g+1260cef+280e^3$
$D^5b^4=84b^3h+756b^2cg+1260b^2ef+1890bc^2f+2520bce^2+1260c^3e$
$D^4b^5=126b^4g+1260b^3cf+840b^3e^2+3780b^2c^2e+945bc^4$
$D^3b^6=126b^5f+1260b^4ce+1260b^3c^3$
$D^2b^7=84b^6e+378b^5c^2$, $Db^8=36b^7c$

$D^9b=n$, $D^8b^2=10bm+45cl+120ek+210fh+126g^2$
$D^7b^3=45b^2l+360bck+840beh+1260bfg+630c^2h+2520ceg+1575cf^2+2100e^2f$
$D^6b^4=120b^2k+1260b^2ch+2520b^2eg+1575b^2f^2+3780bc^2g+12600bcef+2800be^3+3150c^3f+6300c^2e^2$
$D^5b^5=210b^3h+2520b^3cg+4200b^3ef+9450b^2c^2f+12600b^2ce^2+12600bc^3e+945c^5$
$D^4b^6=252b^3g+3150b^4cf+2100b^4e^2+12600b^3c^2c+4725b^2c^4$
$D^3b^7=210b^6f+2520b^5ce+3150b^4c^3$
$D^2b^8=120b^7e+630b^6c^2$, $Db^9=45b^8c$.

We shall conclude this article by recommending that the process of derivation should be introduced, without demonstration of course, into elementary books of algebra, as one of the best exercises of simple algebraical operation. We are firmly of opinion that the arithmetician and the analyst should be trained early in the performance of operations in which numerous details, each very simple in itself, follow one another in rapid succession with much sameness and some diversity. For this reason we should recommend, in arithmetic, Horner's process [Involution and Evolution]; and in algebra, Arbogast's derivation. We proceed accordingly to divest this method of the phraseology of the differential calculus, and to put it before the elementary student in algebra.

The name of the process is *derivation*; its primary object the raising of any power of an expression of the form $b+cx+ex^2+fx^3+$, &c. immediately, that is to say, by writing down the result at once, without any but simple mental processes in passing from term to term. The rules are as follows:

1. Begin with that power of b which is to be raised.

2. To pass from the coefficient of one power of x to that of the next, multiply each letter by its exponent; then diminish that exponent by a unit; then introduce the next letter. And if this last process increase an exponent, owing to the letter newly introduced having been in the term before, divide by the increased exponent. *But remember never to operate on any letter except the last in the term, or the last but one;* upon the last always, upon the last but one when it immediately precedes the last in the original series b, c, e, f, &c.

3. If $b+cx+$, &c. be not an infinite series, but a finite number of terms, operate as if the succeeding letters were severally equal to 0: for instance, if g be the last letter, drop every term in which h should appear, as fast as it arises.

For example, the fifth power of $b+cx+ex^2+fx^3$. Begin with b^5, derive from it $5b^4c$, the two first terms are $b^5+5b^4c\,.\,x$.

To form the coefficient of x^2, take $5b^4c$, and observe that b and c follow each other in the series, so that in the next derivation there are two processes. First, use c or c^1, the last letter, which by the rule gives $1c^2e$ or e: so that derivation applied to the first power of a letter gives merely a change of that letter into the next: hence $5b^4c$ gives $5b^4e$. But b^4, which must also be used, gives $4b^3c$, and $5b^4c$ gives $5(4b^3c)c$; so that c becomes c^2, and we must therefore divide by the increased exponent 2, giving $10b^3c^2$. Hence the next term is

$$(5b^4e+10b^3c^2)x^2.$$

In the next derivation $5b^4e$ gives only $5b^4f$, for b not immediately preceding e in the series b, c, e, &c. is not used. But $10b^3c^2$ gives

$$10b^3(2ce)+\frac{10(3b^2c)c^2}{3}, \text{ or } 20b^3ce+10b^2c^3.$$

Next term $(5b^4f+20b^3ce+10b^2c^3)x^3$.

In the next derivation $5b^4f$ must be neglected entirely, because f is the last letter, and b is not the one immediately preceding. Also $20b^3ce$ gives $20b^3cf$ and $20b^3ec\div 2$ or $10b^3e^2$; while $10b^2c^3$ gives $30b^2c^2e$ and $2\times 10bc.c^2\div 4$, or $5bc^4$. The whole value of $(b+cx+ex^2+fx^3)^5$ is as follows, and a little practice would enable any one to write it down at once, without any intermediate operations:

$$\begin{aligned}
&b^5+5b^4cx+(5b^4e+10b^3c^2)x^2+(5b^4f+20b^3ce+10b^2c^3)x^3\\
&+(20b^3cf+10b^3e^2+30b^2c^2e+5bc^4).x^4\\
&+(20b^3ef+30b^2c^2f+30b^2ce^2+20bc^3e+c^5)x^5\\
&+(10b^3f^2+60b^2cef+10b^2e^3+20bc^3f+30bc^2e^2+5c^4e)x^6\\
&+(30b^2cf^2+30b^2e^2f+60bc^2ef+20bce^3+5c^4f+10c^3e^2)x^7\\
&+(30b^2ef^2+30bc^2f^2+60bce^2f+5be^4+20c^3ef+10c^2e^3)x^8\\
&+(10b^2f^3+60bcef^2+20be^3f+10c^3f^2+30c^2e^2f+5ce^4)x^9\\
&+(20bcf^3+30be^2f^2+30c^2ef^2+20ce^3f+e^5)x^{10}\\
&+(20bef^3+10c^2f^3+30ce^2f^2+5e^4f)x^{11}\\
&+(5bf^4+20cef^3+10e^3f^2)x^{12}+(5cf^4+10e^2f^3)x^{13}\\
&+5ef^4x^{14}+f^5x^{15}
\end{aligned}$$

This process, so simple as compared with the actual performance of the four multiplications, has hitherto lain hid in works on the higher parts of the differential calculus: it is time it should take its place in every system of algebra which contains the binomial theorem, of which it is the legitimate extension.

TAYLOR, JOHN, LL.D., was born about the year 1703, at Shrewsbury, where his father, according to some writers, was a poor shoemaker, or, according to others, a barber. He received his early education at the grammar-school of his native place, and afterwards went to Cambridge, where he entered St. John's College, of which he became a fellow in 1730. The great reputation which he soon acquired as one of the best Greek scholars in the University, procured him the office of librarian of the University library, which however he afterwards exchanged for that of registrar of the University. His first work of importance was his edition of the Greek orator Lysias, under the title 'Lysiae Orationes et Fragmenta, Graecè et Latinè: ad fidem codicum MSS. recensuit, notis criticis, interpretatione, cucteroque apparatu necessario donavit Joannes Taylor,' London, 1739, 4to. The year after he edited at Cambridge an octavo edition of the same orator for the use of students, with short notes and a useful index of the language. The study of the Attic orators led him

to the study of the Attic law, of which he probably possessed a better knowledge than any man of his age. He was also fond of the study of the Roman and English law, and he resolved to devote himself to the legal profession. In 1741 he was admitted an advocate in Doctors' Commons, and the year after he took his degree of doctor of laws. On this occasion he published a Latin dissertation, 'Commentarius ad Legem Decemviralem de Inope Debitore in partes dissecando,' which is a very unsatisfactory explanation of this difficult subject. Soon after this he published an edition of two Greek orations, 'Orationes duae, una Demosthenis contra Midiam, altera Lycurgi contra Leocratem, Graecè et Latinè,' with notes and emendations, Cambridge, 1743, 8vo., and in the same year he published the 'Marmor Sandvicence, cum Commentario et Notis,' Cambridge, 1743, 4to. This volume also contains a useful dissertation on this celebrated inscription, which had been brought from Athens to London by Lord Sandwich in 1739. In 1744 Dr. Taylor was made chancellor of Lincoln; and some years later he took holy orders, though without abandoning the study of the law and of the antient writers. He was now successively made archdeacon of Buckingham and rector of Lawford in Essex, to which, in 1757, was added the lucrative place of canon residentiary of St. Paul's. In 1755 he published at London, in 4to., his 'Elements of Civil Law,' a second edition of which appeared in 1769. Dr. Taylor undertook this work at the suggestion of Lord Carteret, who had intrusted him with the education of his grandsons, whom he wished to be instructed in the principles and history of the civil law. The work displays great learning and knowledge of the subject, but it is not well adapted for the use of beginners; an abridgement of it appeared in 1773, in London, under the title 'A Summary of the Roman Law.' During the last period of his life, Dr. Taylor had made extensive preparations for a new edition of the Greek orators. One volume (which is the third) appeared in 1748 at Cambridge, but his death on the 4th of April, 1756, prevented the author himself from completing the work, though all the materials were ready for press. The second volume appeared after his death, in 1757. The work bears the title, 'Demosthenis, Æschinis, Dinarchi, et Demadis Orationes: Graecè et Latinè, cum notis edidit J. Taylor.' The notes, which were published at a later time, are incorporated in Reiske's 'Apparatus Criticus' to Demosthenes. In a critical point of view the edition of Taylor is not of any great worth, and its chief value consists in his notes in illustration of the history of the orations and the Attic law. Dr. Taylor is said to have been a most amiable and disinterested man: he had considerable taste for poetry, and some specimens of his muse are printed in the 'Gentleman's Magazine,' and in Nichols's 'Select Collection of Poems.'

(Aikin and Johnston's *General Biography*, vol. ix., p. 337, &c.; Reiske, *Praefatio ad Demosthenem*, p. 42, &c.)

TAYLOR, SIR ROBERT, born in 1714, was the son of a London stone-mason, who was more prosperous than prudent, for he affected a style of living very unusual at that period among persons engaged in business: he kept his carriage, and also his country-house in Essex. Towards his son, on the contrary, he appears to have been far from liberal, as he bestowed on him only a common school education, and then placed him under Sir Henry Cheere, a seulptor, whose chief work of note is the statue of Col. Codrington, in the library of All Souls, Oxford. On quitting Cheere, he was furnished by his father with just sufficient money to proceed to Rome, where he was obliged to live with the utmost frugality. His studies in Italy were however of no long continuance, for he was soon summoned home by the intelligence of his father being dangerously ill; upon which he hurried back to England with as much expedition as the state of the Continent would then permit, and was obliged to disguise himself as a Franciscan friar. On reaching home, he found that his father was dead, and that he had left nothing. Thus thrown entirely upon his own resources and ability, all that remained for him was to set up business as a statuary, and he first brought himself into notice by Cornwall's monument. His principal other works in seulpture are Guest's monument, near the north door of Westminster Abbey, the figure of Britannia at the Bank of England, and the bas-relief in the pediment of the Mansion-house, London. After this he abandoned seulpture for architecture, and one of his earliest productions in his new profession was the mansion erected by him for Mr. Gower, near the South Sea House. In 1756-58 he was employed in the alterations of old London Bridge in conjunction with Dance, and thenceforth upon a number of buildings both public and private; yet very few among which display much architectural taste, and least of all any of that richness in decoration and detail which might have been expected from one who had been brought up and had practised as a sculptor. The wings added by him to the Bank of England (afterwards swept away by his successor Soane) were at the time termed 'magnificent,' but then it could only be by comparison with the older building by Sampson, to which they were attached. This design itself was only borrowed from one of Bramante's [BRAMANTE], and was upon so small a scale as to look insignificant in such a situation. The 'Stone Buildings' at Lincoln's Inn are such a mere architectural blank, that the columns, instead of diminishing the poverty of its character, serve only to render it the more apparent. There is however some architectural character displayed in that which is called the 'Six Clerks' Office,' situated between the other building and Chancery Lane. The villa which he built for Sir Charles Asgill at Richmond is at least unexceptionable in taste, though it hardly deserves the admiration it has obtained. Among his other works, Lord Grimston's seat at Gorhambury is one of the best. If not very great, he was eminently successful, in his profession, and obtained several lucrative appointments and surveyorships to the Admiralty, Foundling Hospital, Greenwich Hospital, and the Bank of England, for which he was well qualified, being a man of most business-like habits, and of most extraordinary diligence and assiduity. He was rarely in bed after four in the morning; was most abstemious in his diet, and drank no wine. Whether in consequence of taking warning from his father's example or not, he seems in almost all respects to have been the very reverse of him in his mode of living; and it is not surprising that his economy, together with the appointments which he held, should have enabled him to realize a fortune of 180,000*l*., though, as he himself used to say, he began the world with hardly eighteen pence. He died at his own house in Spring Gardens, September 27, 1788, and was buried in St. Martin's church. He gave the whole of his property to his only son, the late Michael Angelo Taylor, M.P., with the exception of a sum to the university of Oxford, to accumulate for a certain term of years and then to be applied to found an institute for the study of modern languages. This bequest having been incorporated with a similar one by Dr. Randolph for a picture and statue gallery, a building was begun in 1841, under the name of the 'Taylor and Randolph Institute,' from the designs of C. R. Cockerell, Esq., professor of architecture at the Royal Academy. Taylor was knighted when sheriff of London in 1783.

(*Gentleman's Magazine;* Cresy's *Milizia;* Dallaway's *Arts in England; Companion to Almanac*, 1842.)

TAYLOR, THOMAS, was born in London on the 15th May, 1758: his parents were respectable in their calling, but not wealthy. At a very early age he was sent to St. Paul's school, and after remaining there about three years he was placed under the care of a relation who held a situation in the dockyard at Sheerness, with whom he resided several years. During this time he applied himself assiduously to the study of mathematics, and also obtained some knowledge of chemistry: he next became a pupil of the Rev. Mr. Worthington, a dissenting minister who possessed considerable classical acquirements, ultimately intending to complete his studies at Aberdeen with a view to the ministry. But a premature marriage and pecuniary difficulties compelled him to relinquish this plan, and to accept a junior clerkship in Messrs. Lubbock's banking-house. While in this employment he devoted his spare hours to the study of Plato and Aristotle and their commentators. At this time, and to the end of his life, Mr. Taylor always devoted at least six hours of every day to study, and when not engaged in business they were generally the first six. Poverty, and the difficulties attending it, were no obstacles to him, and he always hoped to emerge from the obscurity they placed him in. He first attracted public notice by an attempt to discover the secret of the perpetual lamp, upon which he gave a lecture and exhibited his experiments at the Freemasons'

Tavern. Though it was a failure, it was marked by some ingenuity and great and curious research; it made him some valuable acquaintances, who encouraged him in another undertaking, which was to deliver a course of lectures on the Platonic philosophy. Introducing himself by such means, he was enabled to procure pupils, to whom he taught the languages and mathematics, having also been appointed to the office of assistant-secretary to the Society for the Encouragement of Arts, Manufactures, and Commerce, which he held for several years: he of course gave up and was glad to be emancipated from the less interesting labours of the banking-house. It was in this situation that he made a more extensive acquaintance among learned and scientific men of all professions, and among men of various ranks who are promoters of arts and sciences, than usually falls to the lot of an obscure individual: but he made something more than mere acquaintance; he acquired many friends who were able and willing to assist him in all his undertakings, and with whose help he finally accomplished all that he had in view, which was to translate the works of all the untranslated antient Greek philosophers. It was an arduous task for one man, and apparently a hopeless one, seeing that Sydenham, with the advantage of a more regular education, being a graduate of Oxford, and a known and acknowledged scholar, had not only failed in his desire to impart knowledge to his less learned countrymen by means of translations, but had been suffered to perish in the attempt for want of patronage, 'to the sorrow and shame (as his biographer says) of every friend of literature:' yet Sydenham was a good man, highly respected, and had many friends, or believed he had: he must have been a recluse, for the circumstances of his death seem to have caused surprise. Mr. Taylor was fond of society, and always in it: there was no appearance of abstraction about him; and a stranger would not have suspected him of being studious; he was always ready to join in conversation with any one who happened to be near him, and upon any subject; there were few subjects upon which he had not read, and he could always amuse or instruct if required. 'Being gifted with a very extraordinary memory, he not only retained the immense store of knowledge he had amassed, but he could bring it all into use at his will:' he was deeply read in things that many like to hear of, though they are no longer studied, sorcery, witchcraft, alchemy, &c., and his fund of anecdote was quite inexhaustible: all this, joined to simple and unobtrusive manners, and irreproachable conduct, made him not only an agreeable companion to many, but to some he became almost a necessary one. Men whose occupations had prevented their reading, though they were desirous of knowledge, were particularly delighted with the company of Mr. Taylor, and such were his great supporters. It was by making friends chiefly that Mr. Taylor, who was as poor as Sydenham, contrived to print works that must have cost more than 10,000*l*., that were not of the most saleable description, and that upon the whole produced no pecuniary profit. The duke of Norfolk printed Plato, and from some unaccountable whim locked up nearly the whole edition in his house, where it remained till long after his decease, but he was attached to Mr. Taylor, and frequently made him his companion at Arundel. Mr. Meredith, a wealthy tradesman retired from business, was a man possessed of sound mental faculties, with no aversion to exercise them. Having read Plato he wished also to read Aristotle in an English translation, and Mr. Taylor was ready to help him to it upon no other condition than his undertaking to print it, which he did; and though he made a losing speculation of it, by printing too few copies, he was so well satisfied with Mr. Taylor's exertions, that he not only assisted him in bringing out some of his minor publications, but settled a pension of 100*l*. a year upon him, which he enjoyed till his death: such munificence and friendship in a man who had earned his money, and knew the value of it, is truly honourable. Mr. Meredith, though not versed in the antient languages, obtained a great knowledge of antient literature; he was a man who thought for himself, and came to just conclusions upon most subjects. Among Mr. Taylor's minor works some will be found dedicated to persons who printed them upon similar terms, and in a few cases gave him the benefit of the whole edition. He never exacted payment for his labour, except in one or two cases with the booksellers, and then he had little enough. But with such means he got over all his difficulties, and he had some, for he was twice married and had several children; his income altogether was about 200*l*. a year. There are some persons who are not at all pleased with Mr. Taylor's attempt to revive certain antient opinions; they neither wished to see some of the works he has translated, nor his remarks upon them in English; but they are the very persons who brought the writers into notice by constantly referring to them, and speaking of them in terms that are neither liberal nor entirely merited. These writers were the supporters of antient opinions and establishments, the failure of most of which is now complete and past recovery; there can therefore be little to object to in their writings, and there is much that is good and worth preserving. For these reasons they found translators in every civilized country but England. It seems then that our professed scholars have not done their duty to the public: if they had given us good translations with their own annotations, the labours of Mr. Taylor would not have been called for, and any remarks he might have made elsewhere would have had little weight, and have been overlooked. There are important works yet untranslated, and there are many translations which are disgraceful to the literary character of our country: it is time then that our scholars should look to these matters, and see that things which must and will be done are well done.

Mr. Taylor, during the last forty years of his life, resided in a small house at Walworth, leading a life of perfect uniformity, and dividing his time between his labours and his attentions to his friends and family. He died on the 1st of November, 1835, of a very painful disease in the bladder, which he bore with extraordinary fortitude and without complaining. He was an Academician by profession and a Stoic in practice; a sincere friend and a delightful companion. His works and translations are:—1, 'The Elements of a New Method of Reasoning in Geometry,' 4to., 1780, a juvenile performance lost or suppressed; 2, a Paraphrase of part of Ocellus in the *European Magazine*, 1782; a translation of the whole work in 1831, 8vo.; 3, 'The Hymns of Orpheus,' 12mo., 1787; second edition, 1824, augmented; 4, 'Plotinus on the Beautiful,' 12mo., 1787; 5, 'A Dissertation on the Eleusinian and Bacchic Mysteries,' 8vo., no date; 6, 'The Rights of Brutes,' 12mo., 1792, in ridicule of Paine's 'Rights of Man;' 7, 'Sallust on the Gods and the World,' 8vo., 1793; 8, 'The Phædrus of Plato,' 4to., 1792; 9, 'The Cratylus, Phædon, Parmenides, and Timæus,' 8vo., 1793; 10, 'Proclus on Euclid,' 2 vols. 4to., 1792; 11, 'Two Orations of the Emperor Julian to the Sovereign Sun and to the Mother of the Gods,' 8vo., 1793; 12, 'Pausanias' Description of Greece,' 3 vols. 8vo., 1794: for this translation, made in such haste that Mr. Taylor nearly lost the use of his right hand from continued exertion, he received 18*l*. The work was in such demand that it sold for a high price, and a second edition was printed in 1824 without consulting the translator, who heard of it accidentally, when it was too late to correct it; a slight compensation was made to him, and he added some notes: this is an illustration of the remarks already made; a work like this should not have been left to a necessitous writer: 13, Five books of Plotinus, 'On Felicity; on the Nature and Origin of Evil; on Providence; on Nature, Contemplation, and the One; on the Descent of the Soul,' 8vo., 1794; 14, 'Cupid and Psyche,' from Apuleius, 8vo., 1795; 15, 'Metaphysics of Aristotle,' 4to., 1801; 16, Hederic's 'Greek Lexicon,' edited, 4to., 1803; 17, 'The Dissertations of Maximus Tyrius,' 2 vols. 12mo., 1804; 18, 'An Answer to Dr. Gillies' Supplement to his New Analysis of the Works of Aristotle, 8vo., 1804; 19, 'The Works of Plato,' 5 vols. 4to., 1804; including reprints of the parts previously translated, and many commentaries taken from MSS., some of which have since been printed in the original language; 20, 'The Pythagoric Sentences of Demophilus;' these are printed with Mr. Bridgeman's translations, 8vo., 1804; 21, 'Miscellanies in Prose and Verse,' 12mo., 1805, 2nd ed. 1820; 22, 'Collectanea,' 8vo., 1806; 23, 'The Emperor Julian's Arguments taken from Cyril, with Extracts from his other Works relative to the Christians,' 8vo., 1809; 24, 'The Works of Aristotle,' 9 vols. 4to., 1812, with copious extracts from the antient commentators, to which are added a dissertation on the philosophy of Aristotle, and a treatise on the elements of

the true arithmetic of infinites, both of which had appeared in a separate form; 25, 'The Six Books of Proclus on the Theology of Plato,' 2 vols. 4to., 1816; 26, 'Theoretic Arithmetic,' 8vo., 1816, containing what had been written on this subject by Theon of Smyrna, Nicomachus, Iamblicus, and Boethius; with remarks on amicable and other numbers, and a specimen of the manner in which the Pythagoræans philosophised about numbers; 27, 'Select Works of Plotinus,' 8vo., 1817; 28, 'Life of Pythagoras by Iamblicus,' 8vo., 1818; 29, 'Iamblicus on the Mysteries of the Egyptians, Chaldæans, and Assyrians,' 8vo., 1821; 30, 'The Commentaries of Proclus on the Timæus of Plato,' 2 vols. 4to., 1820; 31, 'Political Pythagoric Fragments and Ethical Fragments of Hieroeles,' 8vo., 1822; 32, 'The Metamorphoses and Philosophical Works of Apuleius,' 8vo., 1822; translated gratuitously at the request of a friend, but purchased by a publisher for 100*l.*: Mr. Taylor had a few copies for his benefit; 33, 'Select Works of Porphyry,' 8vo., 1823; some Essays are added; 35, 'All the Fragments that remain of the Lost Writings of Proclus,' 8vo., 1825; 36, 'Arguments of Celsus relative to the Christians, taken from Origen, with Extracts from other Writers,' 12mo., 1830; 37, 'Proclus on Providence and Evil,' 8vo., 1833; 38, 'Plotinus on Suicide, with Extracts from Olympiodorus, and two books on Truly Existing Being, &c., with Notes from Porphyry and Proclus,' 8vo., 1834. Besides these, there are many papers written by Mr. Taylor in the 'Classical Journal' and other periodicals, amongst which may be specified a complete and valuable collection of the Chaldæan oracles, republished by Mr. Cory.

TCHERNIGOV. [Czernigof.]

TEA. [Thea.]

TEA, PARAGUAY, or MATE', is the produce of a plant belonging to the family Aquifoliaceæ. It was formerly supposed to be the produce of the *Ilex vomitoria*, which is found in North America, in the Carolinas, and Florida; but, from specimens sent from Brazil to Mr. Lambert, it appears to be a distinct species, which he has named *Ilex paraguanensis*. It is a shrub attaining the size of the orange-tree; it is quite smooth, with bluntish wedge-shaped remotely serrated leaves, with umbelliferous flowers seated in the axils of the leaves. It is the *Ilex Maté* of Saint Hilaire, and grows wild in Paraguay and Brazil, and is called by the Spaniards *Yerva Mate*. The leaves of this shrub are in great repute amongst the inhabitants of South America, and are used in infusion in a similar manner to the tea of China. Upwards of 5,000,000 lbs. of the leaves of this tree are annually collected in Paraguay, and are sent to Chili and the viceroyalty of Buenos Ayres. It is not cultivated, and merchants carry various articles of use into the interior, which they give the natives for their labour in collecting the leaves of the plant. After the branches are cut away, the ground is heated by means of a fire, and the branches, being laid upon the heated ground, are dried, and afterwards they are beaten and pressed into bags, in which state it comes into the market. There are three kinds known in the market: the *Caa-cuys*, which is the bud of the leaf; the *Caa-mini*, the leaf torn from its midrib and veins without roasting; and the *Caa-guazu*, or *Yerva de Palos* of the Spaniards, the whole leaf with the petioles and small branches roasted. The first does not steep well, and is seldom seen. The plant when used is steeped in boiling water, to which a little sugar and sometimes lemon-juice is added. It is drunk out of a vessel called *maté*, which has a spout perforated with holes for the purpose of preventing the powdered herb from passing out with the fluid. The Creoles are passionately fond of this infusion, and never partake of a meal without it. The properties of this plant are sedative and stimulant.

Another species of Ilex, the *I. Gonghona*, found in Brazil, is applicable to the same purposes as the last; and although inferior in quality, was used extensively as a substitute for the true Paraguay tea, when the export of the latter from Paraguay was forbidden by the dictator Francia.

The *Ilex vomitoria* produces the *Cassena* of Florida and the Carolinas, which is used for the purpose of correcting the flavour of water.

TEAK. [Tectona.]

TEAL (*Querquedula crecca*, Steph.; *Anus crecca*, Linn.), one of the smallest of the *Anatidæ*, and most beautiful of the Ducks, in which article will be found Mr. Swainson's observations on the subgenus denominated *Teals*, together with a description of the *Blue-winged Teal*.

Description of the *Common Teal.*—*Adult Male.*—Top of the head, cheeks, and neck of a deep chestnut; throat black; a broad band of fine glossy green passing from the eyes to the back of the neck, bordered by a pale margin inclining to yellowish; head and cheeks chestnut; back, scapulars, and flanks zigzagged with irregular alternate lines of black and white; breast and under parts yellowish-white, but the breast is spotted with blackish; wing-coverts brown; beauty-spot (speculum) rich glossy green, deepened at the sides into a velvety black; quills brownish-black; under tail-coverts buff, with a longitudinal black band; bill black; iris brown; legs blackish-brown.

This is the nuptial dress; but, in July and August, this brilliant livery is exchanged for the more sober hues of the

Female.—Top of the head Sienna yellow, with dashes of deep brown; throat and cheeks dusky white, sprinkled with brown spots; plumage above tarnished or dull brown, each feather with a margin of a lighter colour; under parts yellowish-white; beauty-spot green.

This is the *Sarcelle*, *Petite Sarcelle*, *Cercelle*, *Cercerelle*, *Alebrande*, *Garsote*, and *Halebran* of the French; *Cercedula*, *Cercevolo*, *Scavolo*, *Sartella*, *Anitrella*, and *Anitra d' Inverno* of the Italians; *Spiegel-Entlein* and *Krickente* of the Germans; *Winter Taling* of the Netherlanders; *Arta* and *Kræcka* of the Swedes; *Kestelort-And* of the Norwegians; *Krik-And* of the Danes; *Cor Ilwyad* and *Brach Ilwyad* of the antient British.

Habits, Geographical Distribution, &c.—Mr. Yarrell, in his 'British Birds,' now nearly complete, and forming a most valuable addition to British ornithology, thus sums up the information extant relative to the habits and locality of this pretty species, which he notices 'as an early and constant winter visitor, making its appearance by the end of September, sometimes sooner than that, and remaining with us till spring has made considerable progress; their numbers are constantly recruited through the winter months by additional arrivals from the northern parts of Europe, and our markets in consequence obtain a regular supply from the various decoys and other modes of capture. Although numbers in spring return again to more northern localities to breed, many remain in this country and pass the summer near fresh-water lakes. That some of them breed here also, in suitable localities, is proved by the fact that, in the summer of 1817, Mr. Youell of Yarmouth had four young birds of the Teal brought to him, which were hatched at Reedham in Norfolk. The authors of the Catalogue of Norfolk and Suffolk birds say also that very small ones have been obtained in company with their parents upon Ranworth Broad, by Mr. Kerrison of that place; and that they breed also on Seoulton Mere. The Rev. Richard Lubbock of Norfolk, in his note to me on this species, says, "the Teal must, in some years, either breed abundantly with us, or migrate hither very early: I have known sixty or seventy Teal come in small parties to the same plash of water at sun-down by the first week in August." The Teal bear confinement well; and at the gardens of the Zoological Society, though restricted to a very small pond, with a margin of thick and high grass, with some low shrubs, have bred regularly for the last five seasons' (Feb., 1842). The eggs are white, tinged with buff, measuring one inch three lines in length, by one inch four lines in breadth. The food of the Teal consists of seeds, grasses, water-plants, and insects in their various states. In confinement they require grain. Some Teal breed about the lakes of Wales, and a few in Romney Marsh. Mr. Selby, who has paid attention to the habits of this species in Northumberland, says, 'our indigenous broods, I am inclined to think, seldom quit the immediate neighbourhood of the place in which they were bred, as I have repeatedly observed them to haunt the same district from the time of their hatching, till they separated and paired on the approach of the following spring. The Teal breeds in the long rushy herbage about the edges of lakes, or in the boggy parts of the upland moors. Its nest is formed of a large mass of decayed vegetable matters, with a lining of down and feathers, upon which eight or ten eggs rest. Dr. Heysham, in his catalogue of Cumberland animals, says that a few Teal certainly breed in the mosses of that county every year.'

White, in a letter to the Hon. Daines Barrington, dated Selborne, July 8, 1773, says, 'Some young men went down lately to a pond on the verge of Walmer Forest to hunt flappers, or young wild ducks, many of which they caught, and, among the rest, some very minute, yet well-fledged wild fowls alive, which, upon examination, I found to be teals. I did not know till then that teals ever bred in the south of England, and was much pleased with the discovery: this I look upon as a great stroke in natural history.'

But to return to Mr. Yarrell, who thus proceeds: 'In Ireland the Teal is found in great numbers throughout the winter, and a few are resident there all the year. Sir Robert Sibbald, and other authorities since his time, notice the teal as inhabiting the edges of the Scottish lakes; Mr. Dunn however says that it is not numerous either in Orkney or Shetland, although the most so in winter; but that a few pairs occasionally remain during summer and breed. They prefer the inland lakes to the sea-shore. Richard Dunn, Esq., sent me word that this beautiful little duck is widely and numerously dispersed over the whole of Norway and Sweden, but is most plentiful in the north during the breeding season. It breeds all over Lapland, both western and eastern, and is very abundant in the Dofre Fiell, within the range of the birch-trees. The eggs vary in number from ten to fifteen. It breeds also in the cultivated districts in all the mosses and bogs. Mr. Proctor says the Teal is pretty common in Iceland. Eastward of Scandinavia it is found in Russia, and is abundant in Germany, Holland, France, Spain, and Italy; visits North Africa in winter, and has been noticed at Smyrna and Trebizond. The Teal was found in the vicinity of the Caucasian range, by Russian naturalists, and is included in catalogues of the birds of various parts of India, China, and Japan. The Teal of North America is distinct from the Teal of Europe and Asia.' (*British Birds.*)

Mr. Gould, in his great work, 'The Birds of Europe,' remarks that M. Temminck names Northern America as among the native localities of the Teal; but Mr. Gould says that he is inclined to dissent from this opinion, for the American examples may always be distinguished by a white crescent-shaped band on each side of the chest near the shoulders. This, together with the absence of the white tertial feather, will constitute, he thinks, fair grounds for a genuine specific distinction.

M. Temminck, in the fourth volume of his 'Manuel,' has himself corrected this error, acknowledging the difference, and referring to Dr. Richardson, 'Fauna Boreali-Americana,' vol. ii., p. 443.

The teal flies vigorously. Drayton, in the 'five and twentieth song' of his 'Polyolbion,' alludes to this power. After celebrating the Duck and Mallard, he continues:—

'And neere to them ye see the lesser dibbling Teale,
In bunches,* with the first that fly from mere to mere,
As they above the rest were lords of earth and ayre.'

Common Teal, Querquedula crecca.

Utility to Man.—This species is one of the most delicate of the ducks. Willughby remarks, that for the taste of its flesh, and the wholesome nourishment it affords the body, it 'doth deservedly challenge the first place among those of its kind.'

In the 'Portraits d'Oyseaux' (1557), the following quatrain celebrates its excellence and alludes to its habits:—

'Bien peu souvent se plonge la sarcelle
Entre deux eaux, de laquelle la chair
Est delicate: aussi coustc elle cher
Autant qu'oyseau, qui soit petit comme elle.'

Accordingly we see it holding a high place in antient feasts. We find it among the 'goodly provision' at the banquet given at the enthroning of George Nevell, archbishop of York, in the reign of Edward IV.: 'Mallardes and Teales, 4000.' The price, in the Northumberland Household Book, is 'Teylles, 1*d.*,' mallards being 2*d.*

In the provision for the marriage of Roger Rockley and Elizabeth Nevile, 14th January, 17th Henry VIII., there appear among the dishes for the first course at dinner 'Teals, 7 of a dish;' and in the account of the expense in the week for flesh and fish for the same marriage, 'Mallards and Teal, 30 dozen,' are charged '£3 11 8.' Also in the charge of Sir John Nevile of Chete, the father of the bride above mentioned, at Lammas assizes, in the 20th Henry VIII., he then being sheriff of Yorkshire, we find 42 shillings charged for 'Mallards, Teal, and other wild fowl.'

TEAM. Nothing is of greater importance in the management of a farm than the cattle which perform the necessary work in ploughing and other operations on the soil, in drawing manure to the land and carrying the produce to market. It is evident that the smaller the expense of the team which does the requisite work in proper time, the greater the profit of the farmer, and every saving in this part of the expense of cultivation is so much added to the clear gain. Wherever the land is only partially cultivated, and a portion of it remains in coarse pasture, which costs little or nothing to the occupier, or where extensive open commons afford cheap food for oxen, these last are naturally employed in farm labour. If four oxen do only the work of two horses, they are maintained at a much smaller expense, and, after working for two or three years, their value is improved for the purpose of fatting for the butcher. The necessary gear is much less expensive, especially where the old yoke is still in use, whether across the neck or the horns. In fact for a poor man who has only a few acres of land, and who is situated near a waste or common, oxen, and even cows and heifers, are by far the most economical team. Many writers on agriculture, who in general have more theoretical than practical knowledge of husbandry, have maintained the general superiority of an ox team over that composed of horses, and have given calculations which appear clearly to establish their point. But, on the other side, it may be observed, that wherever arable land is the chief object of the farmer's attention, and the tillage of the soil is brought to any degree of perfection, there oxen are never seen at work, but have been invariably superseded by active horses.

It has been urged that at Windsor Park, where it may be supposed that the farms in which George III. took so much interest were conducted by the most experienced agriculturists, a considerable team of oxen was kept, and did most of the work, even the carrying on the roads. This is a confirmation of what we have observed before. The oxen feed on the grass of an extensive park, the value of which is not brought to account. They are very lightly worked, and fatten well after two or three years' work; but if a rent had to be paid for their pasture, or if it were calculated how many young oxen and heifers or sheep could have been kept on the pasture consumed by the oxen, and the profit of these were set against the value of the work done, it would probably appear that there was no great economy in the ox-team compared with the horses. In Switzerland, which is tolerably advanced in its agriculture, oxen are very generally used for the work of the farm; but there the system of stall-feeding is universal, and having a considerable portion of grass-land, which can be irrigated by the streams from the mountains, they eat the coarse long grass produced there for their cows and oxen; and this food is more congenial to their nature than to horses, which do not thrive on coarse watery grass, and require hay and corn nearly all the year round. But where there is less grass-land and more artificial grass, such as lucerne, sainfoin, and clover, which is the case in all ex-

* 'The word in Falconry for a company of Teale.'

tensive farms, there horses are chiefly used, this food being suited to their constitution. Not to enter further into the comparative advantage of oxen and horses, we shall turn our attention to the most profitable management of the latter, which now almost universally compose the farmer's team.

The choice of the horses for a farm is of great importance. It may be very satisfactory to a rich farmer to see fine large well-fed horses in his waggon, moving along as if they followed a procession, with bright harness ornamented with shining brass. This is a luxury like that of the rich man's coach-horses, and as such is very natural and innocent. It is the pride of many a wealthy yeoman, and we would not curtail his pleasure or despise his taste; but as a matter of profit or loss the case is very different: a fat horse does little work, no more than a fat coachman. Horses to be in working condition should be muscular and active. The great heavy cart-horse may, for a moment, be capable of a greater exertion at a dead pull, his weight assisting him; but in a long day the thin active horse will do with ease what would sicken, if not kill, his heavy companion. Horses about fifteen hands high, with short legs and broad chests, such as the Suffolk punches, which walk as fast as an ordinary man, or the active Scotch horses, which have more blood and will readily trot with a moderate load, are the most economical for farm-work. A pair of such horses will draw a load in a cart sixteen miles and return, or plough a Scotch acre of land, equal to one acre and a quarter imperial measure, in ten working hours, having a rest of two hours; while the heavy slow South-country horses could not walk the distance in the time without being over-driven. This is more than the average work; but in the busy time of the year it is a great advantage to have horses which can, with good feeding, work longer and faster without suffering in their health. The carriers on the roads, who live entirely by the work of their horses, know how to choose them and how to feed them to the greatest advantage, and, without over-working them, to make them do as much as is consistent with their health. If hard work is the cause of some diseases in horses, comparative indolence causes many more. Where horses are sluggish, the men soon become so likewise. To see a waggon with four strong horses returning empty, at the rate of two miles in the hour, with two men, or at least a man and a boy, lying lazily in it, is a sure sign that the work on the farm to which they belong is done at the same rate. A single-horse cart, or a light spring waggon with two horses, driven by a man or boy with reins and a whip, and trotting at the rate of five miles an hour, is a perfect contrast to this, and no doubt the owner has his work done much more expeditiously, and consequently at a cheaper rate. The stage-coach proprietors have generally very light four-wheeled carriages to carry their corn from their chief stations to places where they keep horses, and they often carry as heavy loads as a farmer's waggon does when carrying corn to market; yet the two horses in the light carriage trot with their load, and the three or four heavy horses of the farmer move at the rate of two miles and a half in the hour at most, both going and returning. It is evident that there is a waste of time and power here, which is so much lost. Horses half-bred between a cart-mare and a blood-horse are reared by some spirited farmers, and if they are more delicate and susceptible of cold than the common cart-horses, they have many advantages: sometimes they inherit so much courage and vigour from their sire, that they become valuable as carriage-horses or hunters, and well repay the expense incurred in rearing them; and at all events they are superior to any others for the work of the farm, and are in general docile and tractable. The only inconvenience arises from their spirit. When any sudden obstruction arises in ploughing, such as a considerable root of a tree or a large stone, they make violent exertions, and sometimes break the ploughs or other implements. In this respect oxen are more phlegmatic, and stop when the collar presses on them; so that in breaking up rough commons or newly cleared woods oxen may be preferred. This is almost the only case where spirit and courage are not an advantage.

With respect to the food of farm-horses, as we observed before, a great saving may be effected by a judicious use of many vegetables and roots which are easily raised on arable land. Various modes of preparing the food have been recommended, such as steeping corn till it sprouts, baking it into bread, or mixing it with boiled roots. All these may have their advantage where economy is the object; but, with the exception of baked bread made of rye, barley, and oats, and slightly leavened, which is perhaps the best food which can be given to slow-working horses, there is nothing so congenial to the healthy stomach of a horse as good hay and dry oats, or beans bruised in a mill and mixed with cut chaff. They require no cooking to be fully digested, and the digestive power of the horse will extract all the nourishment which they contain. But there are cheaper fodders than hay and corn, especially in summer, when they can be given fresh and green. Tares, clover, lucern, and sainfoin, cut as they are wanted, will keep a horse in health and working condition with little or no corn, and at a comparatively trifling expense; carrots are peculiarly relished by horses, and are very wholesome; and Swedish turnips, or ruta baga, given raw in moderate quantities make their skins shine, and thus prove that they tend to keep them in condition. Every prudent farmer takes care to have a sufficient supply of these cheaper substitutes for hay and corn, keeping these last as a reserve and auxiliary to the former. In a prize Essay of the Highland and Agricultural Society on the comparative advantages of raw and boiled grain as food for farm-horses, the author adduces some experiments, which lead to the conclusion that there is no advantage in boiling grain, but rather the contrary. The cost of keep of a horse per day on different food has been given as follows:—

10 lbs. of straw cut into chaff		1*d.*
10 lbs. of oats, at 3*s.* per bushel		9
16 lbs. of turnips, at 10*s.* per ton		1
Expense of cutting		1½
	1	0½
or—16 lbs. of hay, at 3*s.* 6*d.* per cwt.		6*d.*
5 lbs. of oats, at 3*s.* per bushel		4½
16 lbs. turnips, at 10*s.* per ton		1
		11½
or—28 lbs. of steamed turnips		3½*d.*
7 lbs. of coals, at 1*s.* per bushel		1
Expense of steaming		½
16 lbs. of straw, at 1*l.* per ton		1½
		6¼

This last appears the most economical food, but steamed turnips and straw only would probably not keep a horse in good working condition, and it is not said how long the experiment was continued, nor whether the horses thus fed lost weight. The food is also valued at a low rate.

It is evident that if farm-horses can be kept in condition for 6½*d.* a day, which is not 4*s.* a week, while on hay and oats, in the common mode of feeding, they will cost more than double that sum, the saving in a year would amount to nearly 10*l.* on each horse; and as every twenty-five acres of a farm of moderately light land will require one horse for its cultivation, there will be a saving of 8*s.* per acre, probably half the rent, and more than half the profit. However this may be, there is no doubt that it is of great importance to ascertain what is, on the whole, the best and cheapest mode of feeding farm-horses; and without entering into minute calculations, it will be found that various artificial grasses may be made to succeed each other, by successive sowings, so regularly, that the horses shall be kept for six months of the year entirely on succulent green food, which will enable them to do all the necessary work, and keep them in good health and condition. Thus with the help of carrots, potatoes, and ruta baga, a great saving of hay and oats may be effected in winter, and these crops will take up much less land for their production than hay and oats, and exhaust the soil less; if we except potatoes, which are more profitably used as human food or to fatten pigs.

The example of tradesmen and manufacturers who keep horses, and cut all the hay which they use into chaff, mixing it with oats, may be good for a farmer to follow, where hay is scarce and beans a good price: but otherwise it is fully as economical to give the hay in racks, provided no more be given at once than a horse will eat up entirely,

and a certain ration be allowed for each horse, which experience has shown to be sufficient. In the cavalry, where great attention is paid to economy, the horses have their rations of hay, oats, and straw according to the exercise they take, or the fatigue they are exposed to: so likewise it should be with a farmer's team. In the old mode of feeding horses with as much hay as they would eat, and two bushels of oats for each horse per week, during at least nine months in the year, and giving them tares or artificial grasses between spring sowing and harvest, when there was less to be done, the expense of a horse was much greater than most farmers could now afford; and more land was devoted to the keep of the team than was necessary. The following is the calculation of the cost of the keep of a horse in this way:—

	£	s.
32 weeks, at 2 bushels of oats per week, at 3s. 6d. per bushel	11	4
20 weeks, at 1 bushel of oats per week, at 3s. 6d. per bushel	3	10
Tares 20 weeks, at 6s. (⅛ of an acre per week)	3	0
Hay 32 weeks, 1½ cwt. per week at 4s. per cwt.	9	12
Shoeing	0	15
Farrier	0	5
Total	£28	6

The hay and oats are at high prices, but at all events a horse cannot be kept in this way under 10s. per week. They are then however in excellent condition, and able to work ten hours per day in summer and eight in winter.

On poor land, where gorse or furze grow readily, a very cheap food is obtained by bruising or crushing the young shoots of the gorse to destroy the sharp spines which injure the mouths of the cattle. Horses reared in large commons are often seen beating the gorse with their feet, and then eating it greedily: instinct here teaches them to prepare their own food; and, if they have a sufficient quantity of it, they get fat and in good condition.

It is of great importance to a person about to hire a farm to know exactly what number of horses will be required for its proper cultivation, and this depends upon many circumstances which must all be taken into consideration, and which will make a very material difference, often as much as half the rent of the land. He is to consider the situation of the farm-buildings, especially the stalls and cattle-yards, where the manure is to be made, with respect to their distance from the fields; the state of the roads and the access to the fields; the distance of a good market-town, and whether the fields lie in a ring-fence or are scattered. A farm of good light loam will require one horse for every twenty-five acres for its cultivation, with an additional one for every 200 acres; that is, 9 horses for 200 acres. The additional horse should be lighter and more active than the rest, for the farmer to ride on and to drive in a light cart: yet it should be capable of supplying the place of any of the others in case of illness or accident, or when extra work is required, as in harvest or seed time. The larger the farm, or rather the fields, the fewer horses are required in proportion to its size, because much time is lost in turning the plough where the furrow is short; and ploughing is always the principal work of the team. If more than two horses are required to plough the ground, the soil must be very compact and heavy, and if this is not compensated by greater fertility, the expense of the horses will much reduce the profit of the farmer. It is the custom in some farms for each ploughman to have the charge of his own horses: but it is far better to make the feeding and cleaning of horses the business of regular servants, who should sleep in or near the stables, and rise very early, so that the horses may be fed and ready to go to work as soon as the ploughman comes. When a man has been eight or ten hours holding a plough, he is not so capable of cleaning and rubbing the horses as one who has only had light work in the day. The horse-keepers can prepare manure, make composts, cut hay and straw into chaff for the horses, mow tares or other green food, or hoe the crops in the season while the horses are at work, and the last thing before they lie down at night should be to give the horses their proper ration of hay and see that their beds are comfortable and everything in proper order in the stables: good grooming is of as great use to a horse as good feeding, and without it they will never be in perfect working condition. The harness should always be cleaned and oiled, and hung up in a separate place, not, as is too commonly done, hung up behind the horses in the stables. There should be no unnecessary ornaments, but strength and simplicity should be studied. The weight and size of the collars is in many places absurd: they cannot be too light, provided they are of sufficient strength. The work in the field when the days are long should be divided so as to give the horses at least two hours rest, during which they should be fed with bread or corn. When the fields are near the stables the horses may be brought home, but a portable manger is easily carried into the field, such as is used at the inns on the roads where carriers stop to bait. In winter it may be as well to finish the day's work with only an interval of half an hour. The time in summer should be from 5 in the morning till 10, and from 2 till 7 if the weather is very warm, resting 4 hours; or from 6 till 11 and from 1 till 6, resting 2 hours. In winter the time is from 7 till 3, resting half an hour or an hour between 11 and 12. With good feeding and grooming this is by no means too hard work when the work requires to be carried on briskly. The heavier and lighter kind of work should be so arranged that when horses have worked hard for a day or two, they may have one or two days of lighter work. In most parts of England the pace of the horses and their daily work are much less than in Scotland: two horses should plough an acre a day or more, on an average, but few farmers can get much more accomplished than three-quarters of an acre, if they plough a good depth or break up clover or grass lays. In the light sands of Norfolk and Lincolnshire they go over much ground; but there the furrows are wide and shallow, and the horses might easily trot with the plough if the ploughman could keep up with them. In Flanders such land is ploughed with one horse only; and the work is well done. There is yet much room for improvement in the use and management of the team on most farms in England.

TEANO. [Lavoro, Terra di.]

TEARS. [Eye, p. 142.]

TEAZLE (*Dipsacus Fullonum*) is a plant which grows wild in the hedges, but an improved variety is carefully cultivated in those districts of England where cloth is manufactured. It is used for the purpose of forming a species of brush with which the finer hairs of the woollen fabric are drawn to the surface, where they produce what is usually called the *nap* of the cloth. The teazle has a fine hooked awn, which very readily insinuates itself into the woollen web, and draws out with it some of the fine fibres of the wool; these are afterwards shorn smooth, and leave the cloth with the fine velvet-like nap which is its peculiar appearance. A further account of the operation of teasling, in the woollen manufacture, is given in Ure's 'Philosophy of Manufactures,' p. 192.

Teazles will grow in any soil; but they grow strongest and best in a stiff loam. They require the soil to be in good heart, and are supposed to exhaust it much; but no great portion of manure is required to obtain a good crop. Like all the tribe of thistles, they grow best on ground newly turned up from grass which has lain some time, and the same ground will not again produce them of so good a quality till after a considerable interval. The wild teazle which grows in hedges appears at first sight to be the same as the cultivated variety: but it is of no use to the cloth-worker from the weakness of the awns, which break off, instead of drawing the wool out of the surface of the web.

The growing of teazles is a peculiar trade, and a kind of speculation. The teazle-grower hires a piece of ground suited to his purpose from the farmer for two years, and pays a considerable rent. If the ground is broken up from grass, it is ploughed as deep as the staple of the soil permits, and as early as possible, if before winter so much the better: the ground is laid in narrow stitches, on which the seed is drilled in April, in rows from 12 to 18 inches apart: moisture is necessary to make the seed germinate. As soon as the plants appear, they are thinned out, and the intervals carefully hoed and weeded. During the summer, the ground is several times dug, or *spaded*, as it is called, to a considerable depth, with very narrow and long spades; this greatly invigorates the plants. In November, some plants may be transplanted from where

they stand too thiek, to the plaees where they have failed. They should stand about a foot apart in the rows. During the ensuing spring, the eultivation is repeated, and earth is drawn up to the plants, but without burying the heart. They soon begin to push up their stems, and are fit to be eut in July, just when the blossom has fallen. As they do not come to proper maturity at the same time, several sueeessive gatherings are made. They are eut with a sharp knife about nine inehes below the head, and tied in small bundles or handfuls: thick gloves are very neeessary in this operation. They must be carried under eover before night, as the rains or heavy dews would injure them. When the sun shines, they are exposed to dry in the same manner as is donc with onion seed, and they are never packed elose until they are perfectly dry. When drying they are usually hung on poles; so that the air may eirculate between the bundles. The bundles are afterwards opened, and the teazles sorted into kings, middlings and scrubs, aecording to their size; 9000 kings or 20,000 middlings make a pack. The serubs or refuse are of little value: sometimes the grower places a certain number in a flat bundle by means of eleft stieks, in which the stems are held and the heads spread out like a fan. In this state they are not only more easily packed, but more readily fixed to the eireumferenee of the drum, on which they form a eontinuous card, which brushes the eloth as it is drawn along while the drum revolves.

Teazles are a very preearious erop; sometimes they produce a very great profit, and at other times a serious loss. Care and cultivation lessen the chances of failure greatly: but the priee also fluetuates so mueh that it is an uncertain speeulation, resembling in this respeet the cultivation of hops. Henee it is undertaken by men who are prepared for the event, and who make the profits of one year repay the loss of another.

Several attempts have been made to substitute artificial teazles, formed of hooks of very fine and elastie steel wire; and at one time there was so mueh appearance of sueeess, as to eause the cultivation of teazles to be neglected: but it was soon found that the wires tore the fine fibres of the wool, especially where there were knots in the thread, whereas the hooks of the teazles gave way, and either bent or broke off before the fibre of the wool was injured. The card made of natural teazles was found far superior to the artifieial substitutes, and for a time the price of teazles rose to an extravagant height from their searcity, while some time before they were quite unsaleable. A quantity of teazles which was sold at one time in Berkshire for 5*l*., being thought perfeetly useless, was taken into Gloueestershire, and there produeed the next year 150*l*. The grower was dead, and they were sold by his exeeutors for what they would fetch. This was exaetly at a time when the artificial eards were given up, and no teazles were to be had. A good erop of teazles is about 10 or 12 paeks on an acre: this is sometimes exceeded, but more often it fails by one-half, and a total failure is not uncommon. The price may average six or seven pounds a pack, so that a good erop is worth more than the land it grew on. The expenses, however, are great, and, taking all the chances, it is a erop which, except in very particular situations and eircumstanees, is not suited to the regular farmer, who should never speculate to any extent.

Although teazles are said to exhaust the ground much, yet from the continual stirring of the soil they render it very fit to grow other crops, provided a proper quantity of manure is used: thus very good crops of wheat have been obtained after a crop of teazles.

Every piece of fine broad-cloth requires from 1500 to 2000 teazles to bring out the proper nap, after which they are useless, the hooks being mostly broken off or worn out. This causes a considerable demand for them in the neighbourhood of eloth manufactories, as in Wilts, Glouees terslure, and Somersetshire. In the new tariff the duty is 3*d*. per thousand, whether from foreign countries or British possessions.

TEBALDE'O or TIBALDE'O, ANTO'NIO, born at Ferrara about 1463, studied medieine, but afterwards devoted himself chiefly to literature and poetical eomposition, both Italian and Latin. The first edition of his Italian poems appeared at Modena in 1498, by his cousin Jaeopo Tebaldeo, apparently unknown to the author, who was vexed at it because he thought that his compositions required some final touches: 'Sonetti, Capitoli, e Rime, ehiamate Opere d'Amore,' 4to., Modena, 1498, afterwards reprinted several times at Milan, Veniee, and other places. In 1519 appeared at Milan another small poem of Tebaldeo, with the title, 'Stanze nuove ad un Vecehio che non amando in gioventù fu costretto ad amare in veechiezza.' A correet edition of Tebaldeo's works is however still wanted. A selection from his pastoral poems has been inserted in the eolleetion entitled 'Poesie Pastorali e Rustieali, raeeolte ed illustrate con note dal Dottore Giulio Ferrario,' Milan, 1808. Bembo and Giraldi, eontemporaries of Tebaldeo, speak of his Italian poems with praise, but they regret that they were too hastily published. Tebaldeo afterwards applied himself to Latin poetry, in whieh he aequired great reputation. He was for a time at the eourt of Mantua, and afterwards settled at Rome, where he became a favourite of Leo X., who speaks very highly of him in some of his epistles, and is said to have made him very liberal presents. After Leo's death Tebaldeo fell into distress, and was obliged to borrow money of Bembo and others. He died at Rome in 1537. A few of his Latin epigrams and other small poems are in several eollections.

(Tiraboseh, *Storia della Letteratura Italiana;* Zeno, *Note alla Biblioteca dell' Eloquenza Italiana del Fontanini.*)

TECTIBRANCHIA'TA, Cuvier's name for his fourth order of Gastropods, described by him as having the branchiæ attaehed along the right side, or on the back. in form of leaves (feuillets) more or less divided, but nonsymmetrical. The mantle eovers them more or less, and contains nearly always in its thickness a small shell. The *Tectibranchiata* approach the Pectinibranchiata in the form of the organs of respiration, and live, like them, in the waters of the sea, but they are all hermaphrodites, like the Nudibranchiata and the Pulmoniferous mollusks.

The following genera are comprehended, by Cuvier, under this order:—*Pleurobranchus*, Cuv.; *Pleurobranchæa*, Meekel (*Pleurobranchidium*, Bl.); *Aplysia*, Linn.; *Dolabella*, Lam.; *Notarchus*, Cuv.; Bursatella, Bl.; *Akera*, Müll.; *Gastropteron*, Meekel; and *Umbrella*, Lam.

Of these *Pleurobranchus*, *Pleurobranchæa*, and *Umbrella* are treated of in the article Semiphyllidians; and *Akera* or *Acera*, and *Gastropteron* or *Gastroptera*, under the artiele Bulladæ. *Aplysia* or *Laplysia* (for Linnæus writes it both ways), *Dolabella*, and *Notarchus* therefore remain to be noticed here.

Aplysia.

M. de Blainville thus defines the Aplysians (*Aplysiacca*) the second family of his Monopleurobranchiata:—

Body not divided, or forming a single soft fleshy mass; four tentaeular appendages always distinet, flattened, auriform; the mouth in the shape of a vertieal slit, with two lateral subeorneous labial plates, and a cordiform tongue beset with dentieles; eyes sessile between the two pairs of tentacles; the branehiæ eovered by a sort of operculum; orifiees of the generative apparatus more or less distant, and united together by an external furrow.

Shell null or incomplete, eonstantly internal.

M. Rang's definition is—

Animal not divided, furnished with four tentaeles with eyes at their anterior base, and sometimes with membranes proper for swimming; the branehiæ in form of a plume, in a dorsal eavity, protected most frequently by a free opereulum at the right side, or simply by the approximated edges of the mantle; organs of generation very distant.

Shell rudimentary or null.

The following is Cuvier's description of *Aplysia:*

Edges of the foot raised into flexible crests and surrounding the back on all sides, being eapable even of being refleeted upon it; head earried on a neek more or less long; two upper tentacles hollowed like the ears of a quadruped; two others flattened at the edge of the lower lip; eyes below the first. On the back are the branehiæ, in form of very eomplieated leaves (feuillets), attached to a large membranous pedicle, and eovered by a small pediele equally membranous, whieh contains in its thickness a horny and flat shell. The anus is pierced behind the branchiæ, and is often hidden under the lateral crests. The vulva is in front on the right, and the penis comes out under the right tentacle. A furrow, whieh extends

from the vulva to the extremity of the penis, conducts the semen at the time of coition. An enormous membranous crop leads to a muscular gizzard, armed within with cartilaginous and pyramidal corpuscles, which accompany a third stomach beset with pointed hooks, and a fourth in form of a cæcum. The intestine is voluminous. These animals feed on sea-weed (*fucus*). A particular gland pours out by an orifice situated near to the vulva a limpid humour, which is said to be very acrid in certain species; and from the borders of the mantle there oozes abundantly a deep purple liquor, with which the animal colours the sea for a considerable distance around when it perceives any danger. The eggs are disposed in long interlaced glairy filaments, delicate as packthread.

Cuvier instances as examples from the European seas, *Aplysiæ fasciata*, *punctata*, and *depilans*.

The acrid humour noticed above probably gave rise to the accounts of the poison of the *Lepus marinus* (an *Aplysia*, and most probably *Aplysia depilans*) among the antients. See, for example, Pliny, *Nat. Hist.*, lib. xx., c. xxi.; lib. xxiii., c. vi., &c.

In the museum of the Royal College of Surgeons in London, No. 625 of the *Physiological Series*, is an *Aplysia alba*, in which the mantle has been laid open on the left side, and the peritoneal membrane dissected away, to show the intestinal canal winding among the lobes of the liver: the tunics of the intestine being thin and transparent, permit the contents of the canal to be distinctly seen; these consist of particles of sand with comminuted fragments of zoophytes and shells: so that it appears that their diet is not merely vegetable, as Cuvier seems to have thought. Bristles are inserted at the mouth and anus; the latter orifice is situated in the branchial cavity, below the gills. No. 626 is the intestinal canal of a larger species of *Aplysia*, distended with similar particles of earthy matter; and the author of the Catalogue remarks that this preparation affords a striking example of the powers of living organized matter, and cannot be contemplated without surprise, when we consider the force that must be exerted to propel a column of such heavy and rude materials along a tortuous canal provided with parietes apparently so inadequate to sustain the necessary pressure. No. 1011 is a small *Aplysia alba*, Cuv., with a portion of the mantle dissected away to expose the branchiæ of an arborescent structure, but more complex and better defended than in the *Doris*, the respiratory cavity being shielded by a thin horny plate or rudimentary shell. No. 1012 is a larger specimen of the same species of *Aplysia*, further dissected, so as to show, in addition to the branchiæ, the heart and pericardium, the mouth and masticatory organs, the stomach, nervous ganglia, and the penis on the right side of the neck. A portion of the shell is left to show how loosely it is lodged between the layers of membrane forming the roof of the branchial chamber; and No. 1013 exhibits another species (*Aplysia Camelus*, Cuv.), showing the branchiæ in their natural position, without dissection, by merely separating the dorsal lobes of the mantle and elevating the roof of the branchial chamber. (*Cat.*, vols. i. ii.)

M. de Blainville divides the genus *Aplysia* into the following sections:

A. Species whose lateral appendages are very wide, divided behind, and depressed.

Example, *Aplysia depilans*.

B. Species whose narrower appendages are united and elevated behind.

Example, *Aplysia vulgaris*.

C. Species whose appendages are very wide, and which have only two tentacles, behind which are the eyes. (Genus *Actæon*, Oken.)

Example, *Aplysia viridis*.

D. Elongated species with a subulate tail; the four tentacles long and slender; the branchial cavity subdorsal, without opercule or shell.

Example, *Aplysia Brongniartii*.

The other genera arranged by De Blainville under the Aplysians are *Dolabella*, *Bursatella*, *Notarchus*, and Elysia.

M. Rang divides Aplysia into two subgenera:

I. The Aplysiæ, properly so called (*Laplysia*, Linn.; *Dolabella*, Lam.; and *Actæon*, Oken).

This subgenus is thus characterized by M. Rang:—

Animal furnished with a dorsal slit, always median and longitudinal; foot large, branchiæ enclosed in the bottom of a cavity, whence their length does not permit them to be protruded, and protected above by an operculum.

Shell rudimentary, calcareous, membranous, hidden in the thickness of the operculum.

1st Group.

Body convex behind, an oblique posterior disk, borders of the mantle closed on the back, and improper for swimming.

Shell triangular and very calcareous.

This group comprises the genus *Dolabella* of Lamarck.

Example, *Aplysia Rumphii*, &c.

2nd Group.

Body narrowed at the two extremities, no disk, borders of the mantle very small and improper for swimming.

Shell subquadrangular and calcareous.

This group, M. Rang observes, is composed of new species, with the exception of one, which was erroneously arranged among the *Dolabellæ*.

Example, *Aplysia dolabrifera*.

3rd Group.

Body narrowed at the two extremities; borders of the mantle dilated and proper for swimming.

Shell subrounded, membranous, and solidified by a calcareous stratum.

M. Rang remarks that this group has for its type the genus *Laplysia* of Linnæus, and he divides it into two sections.

A. A tube at the membrane of the operculum.

Example, *Aplysia fasciata*.

B. An aperture at the membrane of the operculum.

II. Subgenus: *Notarchus*, Cuv.

The other genera arranged by M. Rang under the Aplysians are *Bursatella* and *Actæon*. (*Manuel.*)

Mr. J. E. Gray makes the *Aplysiadæ*, the 2nd family of his 3rd order (*Pleurobranchiata*), consist of the genera *Aplysia*, *Dolabella*, and *Notarchus*. The family is placed between the *Bullidæ* and the *Umbrellidæ*.

As an illustration of the genus *Aplysia*, we take *Aplysia depilans*.

Description.—Blackish, with large cloudy greyish spots or blotches, or of different shades of brown tinged with blue or purple.

Locality and Habits.—European seas, where it adheres to rocks.

Aplysia depilans.

Dolabella.

Cuvier observes that this form only differs from the *Aplysiæ* in having the branchiæ and that which surrounds them at the posterior extremity of the body, which resembles a truncated cone. Their lateral crest, he adds, does not close on the branchial apparatus, leaving a narrow furrow, and their shell is calcareous.

Locality and Habits.—East Indian seas, and Mediterranean, where it has been found at a depth of six fathoms on sands.

The Laplysians of Lamarck consist of the genera *Aplysia* and *Dolabella* only; and M. Deshayes, in the last edition of the 'Animaux sans Vertèbres,' thus sums up the information on the subject. Lamarck, he observes, knew little of the animals of this family, though he had indeed seen some species preserved in spirit of wine in the anatomical collection of the museum. Thus he only admitted the two genera last above named into the family. Since the publication of Lamarck's work, M. de Blainville, in his monograph of the *Aplysiæ*, and, above all, M. Rang, in his

Shell of Dolabella Rumphii. 1, inside; 2, outside.

Natural History of the Aplysians,' have, he remarks, added many important observations on the animals of this group. M. Rang, in his work, having especially studied the Aplysians, has, as we have above seen, proposed to admit into this family three genera only, *Aplysia*, *Bursaletta*, and *Actæon*, and he divides the great genus *Aplysia* into subgenera, among which is found the genus *Dolabella*, Lam. There too is to be found the genus *Notarchus*, Cuv. This last, observes M. Deshayes, has in fact much analogy with the Aplysians, but it preserves some peculiar characters capable of easy distinction; and he thinks that the great genus *Aplysia*, as considered by M. Rang, ought to be adopted. Lamarck established his genus *Dolabella*, and separated it from *Aplysia* because the shell is calcareous, and not entirely corneous, as in that genus. Lamarck, without doubt, continues M. Deshayes, would have perceived the little value of this character if he had been able to examine as many species as did M. Rang: he then would have seen the establishment by insensible gradations of a passage between *Dolabella* and *Aplysia*, not only with reference to the form of their shells, but with regard to their consistence also. With regard to the posterior truncation of the animal of *Dolabella*, *that* may be seen to disappear insensibly, so that there exist *Dolabellæ* with a calcareous shell, having entirely the external form of *Aplysiæ*. If, on the one hand, we see the *Aplysiæ* with calcareous shells (Dolabellæ) pass into those with corneous shells, we perceive on the other hand *Aplysiæ* with horny shells pass into species which have no trace of such protecting body. These remarkable species have the lobes of the mantle less slit, more closed upon the back, and nevertheless preserving the principal characters of the true *Aplysiæ*. M. Rang has established on these species his subgenus *Aclesia*, remarkable for the singular tentaculiform appendages on the bodies of the species which form it. Next to *Aplysia* M. Rang places *Notarchus*, and the *Notarchi* are *Aplysiæ* which have only two tentacles, and whose mantle is more closed on the back than it is in the preceding genus; the foot is extremely narrow, it is terminated anteriorly by a double lip, and resembles rather the foot of the *Scyllææ* and other mollusks which creep on the stems of sea-weeds, than that of the *Aplysiæ*. It is to be wished, adds M. Deshayes, that the *Notarchi* could be found in sufficient numbers for dissection, by which means all doubt with regard to them would vanish. After the genus *Aplysia*, M. Rang places *Bursatella*; and M. Deshayes remarks that this genus has so great an analogy with *Notarchus*, that a new anatomy of the former is much to be desired. The animal seen by M. de Blainville was much contracted in the spirit, and its body was beset with a small number of tentacular appendages, which approximate it to the subgenus *Aclesia*, whilst in form it appears to come nearer to *Notarchus*. The last genus, says M. Deshayes in conclusion, placed in the family of Aplysians by M. Rang, is the *Actæon* of Oken, which is not sufficiently known to be definitively admitted into the system; so that the family of Aplysians may be rigorously reduced to the genus *Aplysia*, as considered by M. Rang.

Notarchus.

Animal furnished with a very small dorsal slit, which is sometimes oblique; foot elongated, and rather narrow; branchiæ often very long, and capable of being protruded out of the cavity; opercular rudimentary or null.

Shell null.

Notarchus Cuvieri.

TE'CTONA, a genus of the natural family of Verbenaceæ, so named by Linnæus from the Indian name (*Tekka*) of the famous Teak-tree (called also *Sagoon*), which is a native of different parts of India, as well as of Burma, chiefly along the banks of the Irrawady, and of the islands from Ceylon to the Moluccas. The genus is characterised by having a 5-6-toothed calyx, which becomes inflated over the growing pericarp. Corol 1-petalled, 5-6-cleft. Stamens 5, but often 6. Germ superior, 4-celled, cells 1-seeded, attachment central. Drupe obtusely 4-sided, woolly, spongy, dry, hid in the calyx. Nut hard, 4-celled. Seed solitary. Embryo erect, without perisperm.

The teak-tree grows to an immense size, and is remarkable for its very large leaves, which are from 12 to 24 inches long and from 8 to 16 broad, and are compared by Oriental writers to the ears of the elephant. The petioles, as well as the young branches and flower-stalks, are all 4-sided and the sides channelled. The inflorescence is in very large terminal panicles, of which the divisions are first cross-armed and finally dichotomous, with a sessile fertile flower in each cleft, the whole covered with a hairy farinaceous substance. The flowers are small, white, and very numerous. As teak timber is so highly valued both for domestic purposes and for ship-building, it is desirable to notice its distribution a little more in detail. The best timber for ship-building was supplied to Bombay from the mountains of the Malabar Ghauts, where the tree is found rather in detached clumps, of some extent however, than in extended forests. It is also found on the mountainous parts of the Coromandel Coast, along the banks of the Godavery up to Poloonsha. It proceeds far into the interior of India, and may be seen in the mountains of Bundelcund, in the form however of only a moderate-sized shrub. Dr. Roxburgh introduced the teak into the low grounds of the Circars as early as 1790, and Lord Cornwallis and Colonel Kyd planted it in Bengal about the same time. The Calcutta Botanic Garden contains a number of these trees. From the Saharunpore Botanic Garden, in 30° 9′ N. lat. (where, its buds being covered with scales, it is enabled to resist cold, besides its leaves falling and giving it a season of rest), the tree has been spread along the Doab Canal; the whole of the intermediate country is suited to its cultivation, and the East India Company have recently ordered the Malabar forests to be preserved. The most extensive forests are however those extending along the banks of the Irrawady, especially in Pegu. A considerable timber-trade has been established at Moulmein, whence Calcutta is supplied with some of the finest teak timber. So much straight timber is taken and the crooked left, that thousand of pieces called 'shin-logs,' and admirably adapted for ship-timbers, are left. The tree grows quickly, straight, and lofty, but requires from 60 to 80 years to attain the proper size and maturity for ship-building.

From extensive experience teak timber has been found the most valuable timber for ship-building, and has been called the oak of the East. The wood is light, brownish-coloured, easily worked, but at the same time strong and durable. It is soon seasoned, and, from containing a resinous oil, resists the action of water, as well as insects of all kinds. It does not injure iron, and shrinks but little in width. Some of the old trees have been found by Dr. Horsfield to have large and beautiful burrs like the Kiabouca wood of commerce. No other part of the tree is known to be converted to much use; but the leaves are said to dye cotton and silk of a purplish colour. They have lately been imported into the London docks carefully rolled up, but for what purpose is not known.

TECTUS. (Conchology.) [TROCHIDÆ.]

TEES. [DURHAM.]

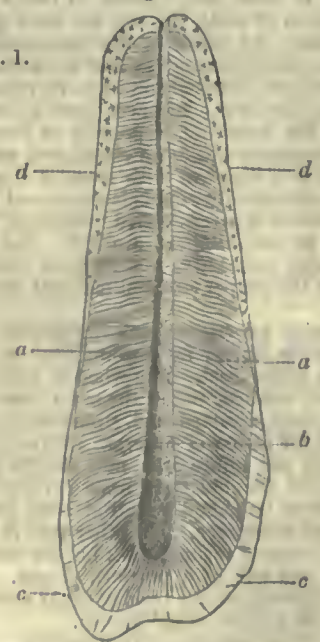
TEETH. Since the article DENTITION was written, the teeth have been subjected to the most careful microscopic examination, and the result has been the acquisition of a great amount of knowledge in regard to both their structure and their mode of growth. Indeed there is probably no part of physiology in which more remarkable and important progress has been made during the last ten years than in this, to which the name of Odontography has been given. The chief discoveries were made coincidentally by Professor Purkinje of Breslau and Professor Retzius of Stockholm. The former published his observations in 1835, in the inaugural dissertation of Dr. Fraenkel (*De penitiori Dentium Structura*), and in that of Dr. Raschkow (*Meletemata circa Dentium Evolutionem*); and the latter communicated his descriptions to the Royal Academy of Sciences at Stockholm, in whose Transactions they were published in 1836. In 1839 Dr. Schwann published, in his 'Mikroskopische Untersuchungen,' an account of the modes in which the several constituent tissues of the teeth are developed; and in the same year Mr. Goodsir (*Edinburgh Medical and Surgical Journal*, vol. li.), carrying out the view before suggested by Professor Arnold, described that method of their early growth which is now generally received as the truth. Mr. Owen also, in his 'Odontography,' and in various papers, at the same time that he has confirmed and greatly added to the facts described by those already mentioned, has proved, by his investigations into their comparative anatomy, that the minute structure of the teeth may be taken as one of the most certain characters for the discrimination of the genera, and even of the species, of both existing and extinct animals; and he has already applied his knowledge of them to the determination of some of the most difficult questions of palæontology.

In the following account scarcely any of the discoveries will be detailed except such as relate to the structure and physiology of the human teeth; for, various as the structures are in the different classes of animals, yet there is so much analogy among them, that the description of the tooth of one will, in great measure, explain the general plan of structure in the rest. Besides, the lately published articles on comparative anatomy contain nearly all the important facts regarding the structure of the teeth in the animals of which they treat.

The best method of preparing teeth for microscopic examination is to immerse them in dilute hydrochloric acid, till their earthy matter is so far dissolved that thin transparent slices may be cut from them with a knife; or, without softening them in acid, to make thin sections, in the vertical and other directions, with a fine saw, and to reduce these to the necessary thinness and transparency by filing them, and polishing them on a hard and smooth whetstone. For general examination, lenses magnifying about 50 diameters are sufficient.

Fig. 1.

Fig. 1.

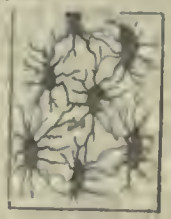


Magnified section of a bicuspid tooth.

In such a vertical section of a tooth three distinct substances are seen; namely, the dentine or ivory (*Fig.* 1, *a a*), which forms the greater mass, and, as it were, the mould of the tooth, and which contains the pulp cavity (*b*); the enamel (*c c*), by which the crown or exposed part of the tooth is covered; and the bone, cement, or crusta petrosa (*d d*), which forms a thin layer around the fang, except at that part at which the vessels enter the pulp, and is continued in a finer and scarcely perceptible layer over the enamel.

The bone, or cement, has in each animal a minute structure similar to that of which the bones of its skeleton are composed. In man it consists of a basis of homogeneous substance, a compound of cartilage and earthy matter, in which there are minute cavities (*Fig.* 2), with delicate branched canals leading from one to the other. On the walls of these canals and cells the earthy matter is deposited more thickly than in the intermediate spaces, so that when examined by transmitted light they appear black or dark grey. The cavities, or *bone-corpuscles*, in man are round or oval, and flattened; most of them are between $\frac{1}{3000}$ and $\frac{1}{1500}$ of an inch in length, about one-third as much in breadth, and one-sixth as much in thickness. They have somewhat jagged edges, from all parts of which there proceed the fine branching canals, to which the name of *calcigerous* has been given, and which traverse the homogeneous basis of the bone, and communicate irregularly with one another. The diameter of these canals, at their largest parts, is not more than $\frac{1}{10000}$ of an inch; that of their smaller branches is between $\frac{1}{10000}$ and $\frac{1}{20000}$. Their general direction is towards the axis of the tooth, around which the corpuscles are arranged in concentric circles.

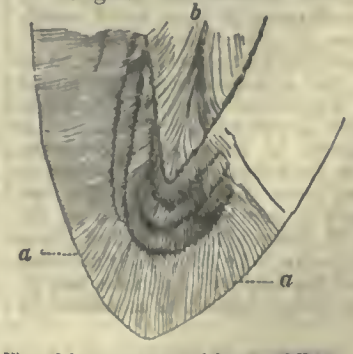
Fig. 2.



Microscopic view of bone-corpuscles and calcigerous canals.

The enamel is composed of solid prisms, or fibres (*Fig.* 3, *a a*), about $\frac{1}{2000}$ of an inch thick, set side by side and upright upon the ivory of the crown of the tooth (*b*). One end of each prism is fixed in a little depression on the rough outer surface of the ivory; the other, which is somewhat larger, is turned towards the masticating surface of the tooth in the direction in which the chief external pressure is to be resisted. The course of the prisms is more or less wavy, their curves being, for the most part, parallel (*Fig.* 4), but sometimes opposed. Most of them extend from the ivory to the surface of the tooth; and where they do not, small complemental prisms fill up, like wedges, the vacant spaces.

Fig. 3.



View of the arrangement of the enamel-fibres on the crown of an incisor tooth.

Fig. 4.

Small collection of enamel-fibres.

In the perfect state the enamel contains so small a quantity of animal matter, that it cannot be demonstrated to the sight, and the prisms are inseparably consolidated; but in young teeth it is soft, and may be broken up into

its elementary parts. In the early state also it exhibits portions of a membranous animal substance, consisting of the cells in which each of its prisms was formed; for, as will be presently shown, the earthy matter is deposited in what might be called a set of moulds formed by the primary cells of the enamel membrane, and, as it accumulates, the membrane of the cell is so nearly removed, that in the perfect tooth no portion of it can be discerned. Its former existence however seems to be indicated by fine close-set transverse striæ upon each prism of the enamel.

The dentine, or ivory, is composed of a hard fibrous basis of cartilage and earthy substance, traversed by very fine, branching, cylindrical tubules, which run in an undulating course from the pulp-cavity, on whose internal surface they open (see *Fig.* 1, *b*) towards the adjacent part of the exterior of the tooth. Each tubule in its course outward makes two or three chief curves ('primary curvatures,' Owen), and is besides bent at every part in minute and very close undulations, or secondary curvatures; but the course of those tubules, which are adjacent to each other, is very nearly parallel. It is from the parallelism of these secondary curvatures of the tubules, that the appearance arises, as if the ivory were composed of concentric lamellæ arranged round the pulp-cavity.

The chief branchings of the tubules of the dentine are dichotomous (*Fig.* 5); but they also frequently give off minute branches, which again sending off smaller ones, fill up the spaces between the trunks (*Fig.* 6). At the trunk each tubule has an average diameter of about $\frac{1}{1000}$ of an inch, and the distance between each two tubules is nearly equal to the width of three of them. Both the walls and the cavities of the tubules, as well as the substance between them, are filled by the earthy constituent of the ivory, which is deposited in fine granules. The basis of the intertubular substance seems to be composed of bundles of flat, pale, granular fibres, whose course is parallel to that of the tubules.

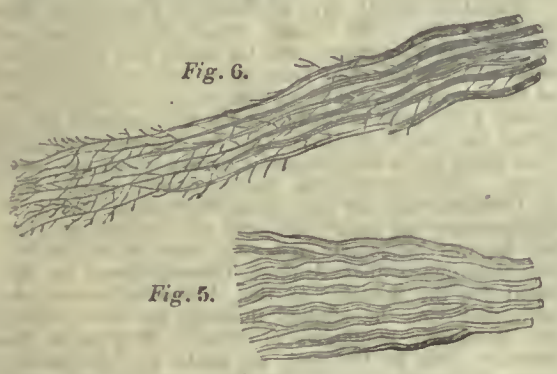


Fig. 6.

Fig. 5.

Views of the tubules of dentines.

A separate organ is provided for the formation of each of these three constituent parts of the tooth, though, when they are perfected, they contain no vascular tissue but the pulp within the pulp-cavity, and it is doubtful whether, in the human subject, fresh material is ever formed from this after the tooth has once attained its complete development. The first appearance of the pulp of each tooth is in the form of a minute process or papilla rising from the bottom of a groove in the mucous membrane of the mouth behind the edge of the jaw. In course of time, as the borders of the groove grow around it, the papilla seems to sink into the mucous membrane; and it now appears as if rising from the base of a follicle, or of a flask-like depression, in the edge of the jaw. And lastly, processes of membrane, or *opercula*, grow from the sides of the mouth of the follicle, and as they approach each other and adhere by their mutually opposed edges, they gradually close it, and convert it into a capsule or sac, to the base of which the first-formed papilla is affixed. In the first-appearing tooth, the papillary state may be seen in the human embryo an inch in length: the capsular stage is completed at about the fifteenth week of embryonic life.

These three stages of the formative organs of the tooth, namely, the papillary, the follicular, and the capsular, being completed, the substances of the tooth itself begin to be produced. The dentine is developed from the papilla, which gradually assumes the form and relations of the proper tooth-pulp; the enamel, from a special organ developed at that part of the capsule which is opposite to the papilla; and the bone probably from the interior of the capsule itself.

The papilla and the sac both gradually increase in size, but the growth of the latter is at first more rapid than that of the former, and the space between them is thus enlarged. Within this space there is deposited from the wall of the sac a soft, granular, non-vascular substance, the enamel-organ, or, as Mr. Hunter (*Natural History of the Teeth*) termed it, the external pulp. And at the same time as this is being produced from the interior of the sac, there is formed on the surface of the papilla a peculiar structureless membrane, which has been called the *preformative membrane*, and which, when the papilla begins to ossify, presents numerous little elevations and depressions, on which the enamel fibres are afterwards fixed; for as the papilla enlarges, the preformative membrane comes in contact with the enamel-organ, and they are exactly moulded the one upon the other.

Both the papilla, or as it may now be called, the pulp, and the enamel, are composed of primary cells [Nutrition], and it is by the transformation of these that the tubules of the dentine and the fibres or prisms of the enamel are severally produced. The exact mode however in which the change is effected is not yet known. All that can be seen is that the superficial cells of the pulp, which are at first round or oval, and nucleated, assume the same diameter and direction as the trunks of the dentine tubules, and then have earthy matter deposited in and around them. And these changes go on gradually from without inwards: as fast as the elongated and branching cells of one layer are ossified, those of the layer beneath them become elongated in preparation for the same change; and so on, till a great part of the pulp is hardened. It is due to this gradual ossification of the pulp from without inwards, that in growing animals, to whom madder is alternately given and omitted in their food, the dentine is found to consist of alternate rings of red and white ivory; for while madder is being taken, all the earthy matter that is deposited in the most superficial layer of the unossified pulp-cells is dyed by its colouring principle, and when it is discontinued the same material is deposited uncoloured in the layer of cells which is subjacent to that already ossified and reddened. When nearly the whole of that part of the pulp which was formed in the original papilla is thus hardened by the deposition of earthy matter, its base begins to grow into one or more conical processes, and, by a hardening of these, through a process like that just described, the fangs are formed, and the tooth rises to the surface of the gum.

In the formation of the enamel, the primary nucleated cells on the inner surface of the enamel-organ become elongated and cylindrical, or prismatic; they assume a direction which is perpendicular to the surface of the hardening pulp; and then, their nuclei disappearing, they also are hardened by the deposition of earthy matter within them, which is continued till they are inseparably compacted, and their original membranous wall is not discernible. These changes also, like the preceding, make progress in layers; but the progress is here from within outwards, and it goes on till nothing is left but a thin external *enamel-membrane* on the surface of the crown of the tooth. As the enamel organ and the papilla, both growing and hardening, approach more nearly to each other, the preformative membrane also disappears.

By the transformation of this enamel-membrane, or of the superficial part of the capsule itself, that part of the bone is produced which envelopes the enamel; and by similar changes in that part of the capsule which has grown in company with the fang-processes of the pulp, that part of the bone is formed which invests the fangs. The changes in this part of the process are probably exactly similar to those through which new bone is produced between a periosteum and the old bone which it surrounds.

TEETH OF WHEELS. [Wheels.]

TEFLIS. [Tiflis.]

TEFZA. [Morocco.]

TEGEA. [Arcadia.]

TEGERNSEE, THE, is a lake in the circle of the Isar,

in the kingdom of Bavaria, about thirty miles from Munich, at the foot of the Bavarian Alps. It is about four miles long, one mile and a quarter broad, and 300 feet deep. This lake gave its name to a Benedictine abbey, which was founded by the Agilolfingers, in the time of King Pepin, was destroyed by the Hungarians, restored in 979, and not abolished till some years after the beginning of this century. The abbots were princes, and had four hereditary offices in their household which were held by noblemen. The late king of Bavaria, Maximilian Joseph, had the abbey converted into a fine palace, which he presented to his consort the late Queen Caroline, with the lordship depending on it, which is about 60 square miles in extent, including the village of Tegernsee, with 300 inhabitants. This palace is situated in a beautiful country surrounded with lofty mountains, among which the Waldberg and the Setzberg are sometimes illuminated when there are royal visitors at the palace. The grounds are laid out with great taste, and the village church is very handsome, and contains some fine paintings. In the vicinity there are quarries of fine marble of various colours, and the mineral springs of Kreuth and Schwaighof. Kreuth is in a very romantic situation, at the foot of high mountains, and is much frequented for its sulphureous waters. Near Tegernsee naphtha is found, which is here called St. Quirinus oil, because it was formerly pretended that it issued from the corpse of St. Quirinus, to whom a chapel in the vicinity is dedicated.

TEHERAN, or TEHRAN. [PERSIA.]

TEHUACAN. [MEXICAN STATES.]

TEHUANTEPEC. [MEXICAN STATES.]

TEIGNMOUTH. [DEVONSHIRE.]

TEIGNMOUTH, JOHN SHORE, LORD, was the eldest son of Thomas Shore, Esq., sometime of Melton in Suffolk, and of his wife Dorothy (other authorities say Deborah) Shepherd. The family was originally of Derbyshire, Lord Teignmouth's great-grandfather having been a Sir John Shore, of Derby, M.D., who was knighted in 1667. Lord Teignmouth was born, it is believed, in Devonshire, October 8, 1751: his father died in 1759, his mother in 1783, and his only brother, the Rev. Thomas William Shore, who was vicar of Sandal in Yorkshire, and of Otterton in Devonshire, in 1822.

Lord Teignmouth went to Bengal in 1769, as a cadet in the Company's civil service, and was first stationed at Moorshedabad as an assistant under the council of revenue. In 1773 his knowledge of that language procured him the appointment of Persian translator and secretary to the Provincial Council of Moorshedabad; and this was followed the next year by a seat at the Calcutta revenue board, which he retained till the dissolution of the board in 1781, when he was appointed second member of the general committee of revenue, established by the new charter granted that year. While holding this situation, Mr. Shore lived in terms of intimacy with Warren Hastings, the governor-general; and when Hastings came home in 1785 he accompanied his friend to England. During this visit to his native country he married Charlotte, only daughter of James Cornish, Esq., a medical practitioner at Teignmouth; and a few weeks after, in April, 1786, he set out again for Calcutta, having been appointed one of the members of the Supreme Council under the new governor-general Lord Cornwallis. To his activity and ascendency in the council is mainly attributed the adoption of Cornwallis's great measure, the new settlement, in 1789, of landed property in the presidency of Bengal, by which the zemindars, hitherto only the revenue agents or tax-gatherers of the government, were made the hereditary proprietors of the estates which they farmed, and the ryots, or peasantry, who had till now a right of occupation so long as they paid their assessments, were declared the tenants of the zemindars, and made removable at the will of their landlords. The new judicial system which was introduced towards the close of Lord Cornwallis's government in 1793, also owed its establishment in a principal degree to Shore, who had been made a baronet the preceding year. On the retirement of Cornwallis, in August, 1793, Sir John Shore was appointed to succeed him as governor-general; and he held that high office till the close of the year 1797, when he resigned it to the earl of Mornington, and was created an Irish peer by the title of Baron Teignmouth.

Upon the death of Sir William Jones, in April, 1794, Sir John Shore was elected president of the Asiatic Society; and taking his seat in that capacity on the 22nd of May, he delivered a discourse on the merits of the late president, which is printed in the fourth volume of the Society's 'Transactions.' After his return home Lord Teignmouth published, in 1804, a 4to. volume, entitled 'Memoirs of the Life, Writings, and Correspondence of Sir William Jones;' and in 1807 he produced an edition, in 13 vols. 8vo., of Jones's Works, with this Life prefixed. Upon his leaving India Lord Teignmouth had been succeeded as president of the Asiatic Society by Sir Robert Chambers, in a discourse by whom, delivered at a meeting of the Society on the 18th of January, 1798, and printed in the sixth volume of their 'Transactions,' there is a sketch of the character and career of his predecessor. In 1804, on the formation of the British and Foreign Bible Society, Lord Teignmouth was elected its first president; and this situation he retained till his death, though for some years before that event he was obliged to devolve its active duties upon his successor, Lord Bexley. In the prosperity of the Society he at all times took the liveliest interest.

On the 4th of April, 1807, Lord Teignmouth was appointed one of the commissioners for the affairs of India, or, in other words, a member of the Board of Control; and on the 8th of the same month he was sworn of the Privy Council. He retained his seat at the Board of Control for some years; and his death took place on the 14th of February, 1834.

Besides the publications already mentioned, Lord Teignmouth is the author of 'A Letter to the Reverend Christopher Wordsworth, D.D., on the subject of the Bible Society,' 8vo., London, 1810; and 'Considerations on communicating to the Inhabitants of India the Knowledge of Christianity,' 8vo., London, 1811. (*Gent. Mag.* for 1834, pt. i., p. 552.)

TEISSIER, ANTOINE, was born at Montpellier, 28th January, 1632. His family, which was originally of Nîmes, was Protestant; and his father was receiver-general of the province of Languedoc, but he was deprived of that appointment, and also of whatever else he possessed, a few months after the birth of his son, for having joined the revolt of Henri, Duc de Montmorenci, or at least given up to him the public money which was in his hands. Montmorenci was taken prisoner at the affair of Castelnaudari, on the 1st of September, 1632; his insurrection was suppressed, and on the 30th of October he was beheaded. After the ruin of his family it was determined that Antoine Teissier should be educated for the ministry of the Protestant church, and with that view he studied theology for some time at the Protestant seminaries of Nîmes, Montauban, and Saumur. But in the end he made up his mind to adopt the profession of the law, induced, it is said, by the weak state of his health; and after having gone through the usual course of study at Bourges, and taken his doctor's degree, he commenced practice as an advocate before the district court called the Presidial, at Nîmes. His bodily strength however proved to be no more sufficient for the bar than it had been thought to be for the pulpit; and after some time he gave up his profession, and took to literature as a means of subsistence. On the revocation of the Edict of Nantes, in 1685, Teissier took refuge in Switzerland, having, according to the 'Biographie Universelle,' although in extreme distress, declined very tempting proposals which were made through the chancellor D'Aguesseau, to induce him to remain in France. But it would no doubt be made a condition that he should abjure Protestantism. He supported himself chiefly at first by publishing a French newspaper at Berne; then by giving a course of public law (droit public) at Zürich; and the works he sent to the press from time to time also brought him something. At length, in 1692, he was invited by Frederic III., elector of Brandenburg (afterwards king Frederic I. of Prussia) to come to Berlin; and there he resided till his death, on the 7th of September, 1715. Immediately on his arrival he had been nominated a councillor of state, and appointed to the office of historiographer; and part of his time was also occupied for some years in superintending or directing the education of the hereditary prince, afterwards Frederic William

I. A complete list of Teissier's numerous publications is given in the 'Biographie Universelle.' The most celebrated among them is his 'Eloges des Hommes Savans, tirées de l'Histoire de M. de Thou,' first published at Lyon and at Geneva, in a 12mo. volume, in 1683; then at Utrecht, in 2 vols., in 1696; and again at Leyden, in 4 vols., in 1715. In the two latter editions the text of De Thou is accompanied by numerous annotations, which display much curious research. Teissier was an accurate inquirer; but there is no artistic quality or vital power in any of his books, and all of them, even including his 'Eloges,' may be said to be now superseded and nearly forgotten. One of the most creditable is a Catalogue, in Latin, of the authors who have written catalogues, indexes, &c., in two parts, 4to., Geneva, 1685 and 1705; some others relate to parts of the history of Prussia; and a great many are translations, which have the character of being generally faithful enough, but of little elegance or spirit, from St. Clement, St. Chrysostom, Calvin, Sleidan, and other Greek and Latin writers, the latter mostly, if not exclusively, moderns.

TEJUCO. [Brazil, p. 368.]

TEJUS. [Sauvegarde.]

TELECLES. [Sculpture.]

TELEGRAPH (from τῆλε, 'distant,' and γράφω, 'write'), a machine or contrivance for communicating intelligence to a distance, usually by means of preconcerted signals, to which some conventional meaning is attached. On this account telegraphic communications may be as remarkable for their impenetrable secrecy as for their rapidity. The name semaphore (from σῆμα, 'a sign,' and φέρω, 'bear'), is commonly applied to some of the machines used for effecting telegraphic communication; which, in an extended sense, may be considered to embrace every means of conveying intelligence by gestures and visible signals, as flags, lanterns, rockets, blue-lights, beacon-fires, &c., or by audible signals, as the firing of guns, the blowing of trumpets, the beating of drums or gongs, &c., as well as by the machines called telegraphs or semaphores.

Although telegraphic communication, as a means of conveying *any* required intelligence, is an invention of recent date, the use of signals for the speedy transmission of such brief messages as might be previously arranged between persons, is a practice derived from the most remote antiquity. The use of beacon-fires, for example, as a means of giving speedy warning of the approach of an enemy, is alluded to by the prophet Jeremiah, who wrote about six centuries before the Christian æra, and who warns the Benjamites to 'set up a sign of fire in Beth-haccerem; for evil,' he adds, 'appeareth out of the north, and great destruction.' (*Jeremiah*, vi. 1.) The fine description given by Æschylus, in his 'Agamemnon,' of the application of a line of fire-signals to communicate the intelligence of the fall of Troy, is often referred to as an early instance of this kind of telegraphic despatch; but if the æra of the writer, and not that of the event, is referred to, the passage above quoted affords an earlier illustration. This simple means of spreading an alarm, or communicating intelligence in time of war, is practised by many nations; and, to come nearer home, we may refer to the graphic stanzas of the 'Lay of the Last Minstrel' (canto iii., st. xxv.-xxix.), descriptive of the rapid communication of the approach of the English forces from the border stations, along 'height, and hill, and cliff,'—

> 'Till high Dunedin the blazes saw,
> From Soltra and Dumpender Law;
> And Lothian heard the Regent's order,
> That all should boune them for the border.'

In a note illustrative of this description, Scott refers to an Act of the Scottish parliament in 1455, c. 48, which directs that one bale or faggot shall be warning of the approach of the English in any manner; two bales, that they are *coming indeed;* and four bales blazing beside each other, that the enemy are in great force. Such signals, though best adapted to give information by night, were also available in the daytime, when they appeared as columns of dense smoke. Torches held in the hand and moved in any particular manner, or alternately displayed and hidden behind a screen, were also used in antient times as signals, as we learn from several early writers on military subjects; but as they were merely arbitrary signals, which admitted of very little variation, such devices could only be rendered available by previous concert.

That some attempts were made by the antients to improve upon such simple signals is evident from the tenth book of Polybius, in which allusion is made to a device of Æneas (Tacticus), who proposed to write several sentences, such as it might be desirable to communicate, upon two oblong boards, one of which should be kept by each of the parties. These boards were to be affixed to cork floats capable of rising and falling in cylindrical vessels of similar form and size, one of which was placed at each station. Matters being thus prepared, and the vessels filled with water, the person desiring to send intelligence allowed the water to escape from his vessel by a small opening until the suitable sentence on the inscribed board had sunk to a certain mark; making torch signals to indicate the moment of allowing the water to run out, and that at which the board sank to its proper level. The person at the distant station regulated the egress of water from his vessel by the torch signals, and was thus enabled to ascertain which of the sentences written on the board conveyed the required intelligence. Complicated as was this arrangement, it afforded very little more scope than the use of simple torches or fires. Polybius however describes a much more perfect method of telegraphic communication, which, he says, was invented either by Cleoxenus or Democlitus, but improved or perfected by himself. This method is capable of communicating any required intelligence with the greatest precision, the signals being made to represent the letters of the alphabet, and the message being displayed letter by letter. Instead of quoting the description of Polybius himself, which refers to the use of the Greek alphabet, we shall adopt that of Bishop Wilkins, who describes the plan as applied to the English alphabet. The alphabet must be divided for this purpose into five portions of five letters each (excepting the last, which has but four, *j* and *v* being omitted as unnecessary), and inscribed upon tablets, as in the following diagram:—

	I.	II.	III.	IV.	V.
1	*a*	*f*	*l*	*q*	*w*
2	*b*	*g*	*m*	*r*	*x*
3	*c*	*h*	*n*	*s*	*y*
4	*d*	*i*	*o*	*t*	*z*
5	*e*	*k*	*p*	*u*	

This being done, each of the corresponding parties is to be provided with a copy of the tablets, and also with ten torches, five of them on the right hand and five on the left. Any letter may then be expressed by first lifting up on the right hand so many torches as may indicate the number of the tablet in which it is contained, as I., II., III., &c., and then so many on the left as may show the number of the particular letter in the tablet, as 1, 2, 3, &c. Thus the word *hasten* would be expressed by displaying the torches six times, in the following order, in which the Roman letters indicate the number of torches raised on the right hand, and the Arabic numerals those on the left:—

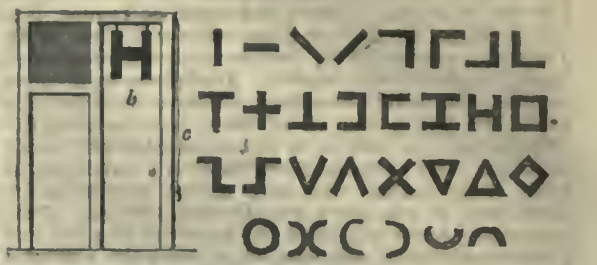
Right hand.		Left hand.
II.	*h*	3.
I.	*a*	1.
IV.	*s*	3.
IV.	*t*	4.
I.	*e*	5.
III.	*n*	3.

Polybius observes that dioptrical instruments, framed with two holes or tubes, should be used to enable the observer to distinguish accurately the right and left hand lights; and that solid fences should be erected upon each side, behind which the torches might be concealed when out of use. Bishop Wilkins, in his curious work entitled 'Mercury; or the Secret and Swift Messenger,' after describing this telegraph of Polybius, mentions another which requires only three lights or torches. The twenty-

four necessary letters of the alphabet are, according to this plan, which he gives on the authority of Joachimus Fortius, to be divided into three classes of eight letters each. The first class is represented by one torch, the second by two, and the third by three; and the number of the letter by the number of times which the torches are elevated or discovered. Thus one torch raised once would represent *a*, or raised eight times, *h*; two torches raised once would indicate *i*, raised twice, *k*; or eight times, *q*; and three torches raised from once to eight times would give the remaining letters, from *r* to *z*. Similar to this, but still easier of application, is the night-telegraph contrived by the Rev. James Bremner, of the Shetland Islands, and rewarded by the Society of Arts in 1816. A single light constitutes the whole apparatus in this plan, and the whole operation consists in its alternate exhibition and concealment. The alphabet is divided into four classes or divisions, of six letters each; and the number of obscurations is to indicate, first, the number of the division, and secondly, the number of the letter in that division; a pause being made between the obscurations which indicate the number of the division and those which show the number of the letter in that division; and a longer pause between the double set of movements thus required for every letter. Two lights, one to represent the division, and the other the number of the letter, might in some cases be used; but Mr. Bremner conceives that, especially in long distances, one is preferable, as affording less risk of error. His plan had been found suitable for distances of twenty miles and upwards, and had been successfully put in operation between the lighthouse on Copeland Island and Port Patrick on the opposite side of the Irish Channel. Further particulars respecting this, and a description of another telegraph for day-service, by the same author, are given in the thirty-fourth volume of the Society's 'Transactions,' pp. 213-227. Tedious as Mr. Bremner's method may appear, it is stated that, supposing the whole alphabet to be used, sixty letters might easily be given in five minutes; while the communication might be effected more rapidly if, as in some telegraphic systems, only sixteen letters were used. In addition to the alphabetic systems which depend merely upon the number or alternate display and concealment of lights, Bishop Wilkins describes one which depends upon the relative positions of two lights attached to long poles, and which, he says, 'for its quickness and speed is much to be preferred before any of the rest.' It will thus be perceived that that ingenious writer came very near to the principle upon which many of the modern telegraphic systems depend. In suggesting the use of extended lines of telegraphic communication, he further hints at the application of the telescope (or, as he styles it, 'Galileus his perspective'), to the deciphering of distant signals.

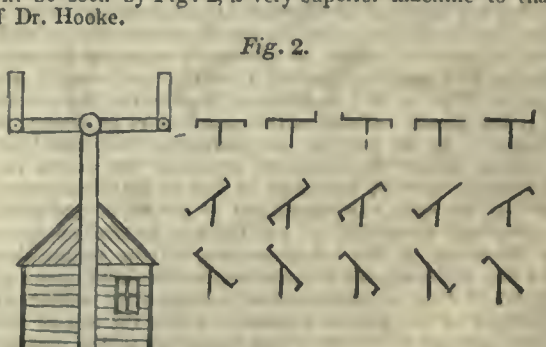
Among the scientific writers who seem to have had some notion of the modern telegraph are Kircher, Schottus, and Kessler; the latter of whom proposed to cut out such characters as it was desired to show in the ends of a cask, which was to be elevated with a light enclosed in it. The Marquis of Worcester also, in his 'Century of Inventions,' 1663, announces, 'How at a window, as far as the eye can discover black from white, a man may hold discourse with his correspondent, without noise made or notice taken,' &c.; and again, 'A way to do it by night as well as by day, though as dark as pitch is black.' The earliest well-defined plan of telegraphic communication appears however to be that described in a paper addressed to the Royal Society in 1684, by Dr. Robert Hooke, and published in 1726 in Derham's collection of his 'Philosophical Experiments and Observations,' pp. 142-150, 'showing a way how to communicate one's mind at great distances.' Hooke states that he had discoursed on the subject some years before, but that the then recent siege of Vienna by the Turks had revived the matter in his mind. His scheme will be readily understood by the annexed cut, *Fig.* 1, which represents an elevated frame-work supporting a panel or screen, *a*, behind which were to be suspended a number of symbols or devices, formed of deal plank, of the various shapes represented by the small black figures. The first twenty-four of these, which consist entirely of straight lines, were to stand for alphabetic characters; and the six devices consisting of curved lines were to be used as arbitrary signals. Whenever it was desired to display any of these characters, they were to be drawn from behind the screen by a rope *c*, passing over pulleys in the frame-work, and so rendered visible in the open space at *b*. These telegraphs were to be erected upon elevated

Fig. 1.



stations, so chosen that, if possible, there might be no refraction of the atmosphere to impede vision, and so that no intervening objects or disturbed background might interfere with the clearness of the prospect; and telescopes were to be used by the observers. The order of connection between the signs employed and the letters of the alphabet might, it is explained, be infinitely varied, for the sake of secrecy; and none of the parties employed, excepting those at the terminal stations, need have any knowledge of the message communicated. Hooke further proposed a scheme for night communication by means of lights disposed in a certain order. About twenty years after the date of Hooke's paper, Amontons brought forward a very similar plan in France, and made public trial of his contrivance before several persons of rank. Some other individuals subsequently devised similar schemes, but nothing was effected in the practical application of telegraphic communication until the war of the French revolution. Macdonald states that, 'Following the principles laid down by Dr. Hooke, in 1684, Dupuis, in France, invented the French telegraph, which Don Gualtier, a monk of the order of Citeaux, in 1781, modified, and proposed to Condorcet, Milli, and Dr. Franklin, who recommended it to the French government.' The telegraph brought into use in 1793 or 1794, by M. Chappe, was, as will be seen by *Fig.* 2, a very superior machine to that of Dr. Hooke.

Fig. 2.

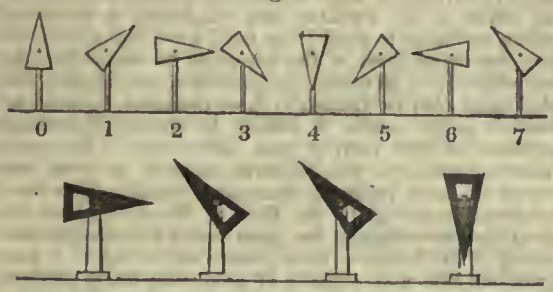


Chappe's telegraph, which, from its position when at rest, is sometimes called the T telegraph, consisted of an upright pole or post, at the top of which was pivoted, by its centre, a transverse beam, which, by means of ropes worked in the chamber below, that served also for an observatory, might be made to assume any required angle with the post. Each end of this moveable beam carried a short arm, that was capable of assuming any required angle with it; and these arms also were worked by ropes, which were conducted through the axis of the beam, in order that the necessary degree of tension might not be disturbed by the action of the machine. By this contrivance, without the use of any angles of less than 45° (which might be indistinct when viewed from a great distance, or under the influence of a refractive atmosphere), as many as 256 different signs might be made. A much smaller number was however sufficient, as M. Chappe communicated his intelligence letter by letter, and simplified the movements by using an alphabet of only sixteen letters. The small figures in the cut show some of the different positions assumed by the beam and arms; and, as the connection between these and the letters they were made to represent was quite arbitrary, their significa-

tion might be changed as often as was necessary for the purpose of secresy; it being only necessary that the key should be known to the parties sending and receiving the message, although it might be transmitted through a great number of intermediate stations. Such telegraphs were first erected on a line commencing at the Louvre, in Paris, and proceeding by Montmartre and other elevated points to Lisle, in order to communicate between the Committee of Public Welfare and the combined armies in the Low Countries. Telescopes were used at each station, and the signals displayed at one station were immediately repeated at the next; four seconds being found sufficient for effecting the required motions, and sixteen seconds the time allowed for observing and noting down each signal, during which the machine remained stationary. Barrère, in announcing the invention of the telegraph to the Convention, on the 17th of August, 1794, stated that the news of the recapture of Lisle had, by means of this machine, reached Paris in an hour after the troops of the republic had entered that place. (*Annual Register*, 1794, p. 51.)

The advantages of such extraordinary celerity of communication were so obvious that, in England and other countries, many plans were immediately brought forward, some of which differed materially from that which had been successfully put in practice in France. Among these was that contrived by Mr. R. L. Edgeworth, who states that he had made experiments as early as 1767, when he proposed to use the sails of a windmill as a means of conveying intelligence by signals. The report of Chappe's telegraph revived the matter with him, and late in 1794 he, with some friends, tried experiments with a numerical telegraph (or a telegraph expressing numbers, which numbers refer to letters, words, or sentences, in a dictionary), on the principle shown in the cut *Fig.* 3. An index, or pointer, in the form of an isosceles triangle, was so mounted upon a post, or on a portable triangular stand, that it might be

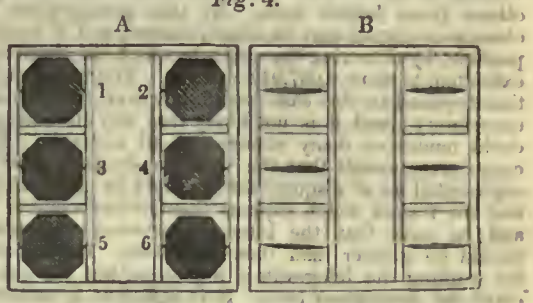
Fig. 3.



turned into any of the eight positions shown in the upper part of the cut; these positions indicating, respectively, 0 and the numerals 1 to 7. Four such pointers, mounted side by side by side, as in the lower part of the figure, afford power for expressing any number from 1 to 7777, excepting 8, 9, 18, 19, 28, 29, and all others in which the numerals 8 and 9 are required: the first pointer representing thousands, the second hundreds, the third tens, and the fourth units. Thus the four black pointers in the figure, being, respectively, in the positions indicating 2, 7, 7, and 4, express, collectively, the number 2774. The numerical system affords at least equal facilities with the alphabetic or lettering plan for secrecy in the communications; since the connection between the numbers expressed and the sentences to which they refer may be changed at pleasure, and none of the persons employed in transmitting the intelligence need to possess the dictionary, the *number* being all that they require to know. In reference to this distinctive feature of his plan, Edgeworth observes that, while '*telegraph* is a proper name for a machine which describes at a distance, *telelograph*, or, contractedly, *tellograph*, is a proper name for a machine which describes *words* at a distance;' and therefore he uses the latter term. In his 'Essay on the Art of Conveying Secret and Swift Intelligence,' published in the sixth volume of the 'Transactions of the Royal Irish Academy,' in which the details of his plan are fully given, Edgeworth notices the great advantages derivable from the application of telegraphic communication to commercial and general purposes, as, for instance, to the speedy announcement of market-prices at a distance; and even hints at the possibility of a line of telegraphs between Europe and the East Indies. He also published a pamphlet entitled 'A Letter to the Right Honourable the Earl of Charlemont on the Tellograph, and on the Defence of Ireland,' which was reprinted at Londou in 1797.

Another of the individuals whose attention was directed to this subject by Chappe's telegraph, was the Rev. J. Gamble, then chaplain to the Duke of York. He issued a thin quarto pamphlet, without date, entitled 'Observations on Telegraphic Experiments,' in which, after noticing several suggestions which had been made for effecting rapid communication, he propounds another, of which he believed himself to be the inventor. The apparatus which he proposed consisted of a frame-work containing five boards, or shutters, arranged vertically one above the other, and pivoted in such a way that any or all of them might be closed, so as to present their broad surfaces to the eye, or opened, so as to present merely a thin edge, which would be invisible at a distance. The various signals produced by closing one or more of these shutters may be applied either to a numerical or an alphabetical system. A similar plan submitted to the Admiralty in 1795, by Lord George Murray, was adopted in the first government line of telegraphs established in England, in 1796, between London and Dover. The 'Annual Register' for that year (p. 4 of the 'Chronicle') mentions the erection of the telegraph over the Admiralty on the 28th of January, and states that information had been conveyed from Dover to London in seven minutes. The action of this kind of telegraph, which was continued in use by the Admiralty until the year 1816, is illustrated by *Fig.* 4, in which A represents a square frame-work with six octagonal shutters, 1, 2, 3, 4, 5, and 6, arranged in two vertical columns, or

Fig. 4.



sets, and turned into a vertical position, so as to display their broad surfaces completely, and B represents the same apparatus with the boards or shutters placed horizontally, or turned one-quarter round upon their respective axes, so as to present nothing but their edges to the eye. The central space between the two columns of shutters serves to render them more distinct to a distant observer, and affords room for the ropes and pulleys by which the telegraph is worked, and which are managed by persons in the observatory below. As shown by the following table, the six-shutter telegraph is capable of expressing sixty-three different signals, by closing one, two, three, or more of the shutters, according to the Arabic numerals in the table, which refer to the numbers inserted in the cut *Fig.* 4, A. The position of the apparatus shown in *Fig.* 4, B, is not counted as a signal; it being the position of rest.

Table of the Separate or Distinct Signals given by the Six-shutter Telegraph.

1	23	124	236	1245	3456
2	24	125	245	1246	12345
3	25	126	246	1256	12346
4	26	134	256	1345	12356
5	34	135	345	1346	12456
6	35	136	346	1356	13456
12	36	145	356	1456	23456
13	45	146	456	2345	123456
14	46	156	1234	2346	
15	56	234	1235	2356	
16	123	235	1236	2456	

These signals affords the means of expressing each letter of the alphabet, and each of the Arabic numerals, by a distinct and simple sign, and still leave several signs unappropriated, which may be applied to words or sentences of common use, or to arbitrary signals; and the connec-

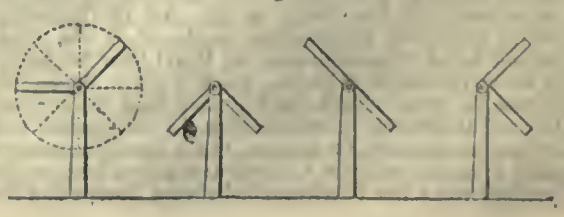
tion between the signals given in the table and the letters or numerals they represent may be varied almost infinitely; so that if, in time of war, the key were to fall into the hands of the enemy, it might be immediately changed. In a modification of this kind of telegraph, intended for night as well as for day service, which was submitted to the Society of Arts, in 1805, by Mr. Joseph Davis, a seventh shutter or board is added, which, instead of being poised on an horizontal axis, is made to slide up and down in grooves in the centre of the framework; so that it may either range with the shutters 1 and 2, 3 and 4, or 5 and 6, or, if not required at all, may descend into a space provided for it in the roof of the observatory. By this simple device the power of the machine is quadrupled; it being rendered capable of making the sixty-three signals shown in the table without the sliding-shutter, and the like number with it in each of its three visible positions, or two hundred and fifty-two changes in the whole.

About the same time that shutter-telegraphs were being introduced in England, the Chevalier A. N. Edelcrantz, of Stockholm, was devising similar machinery for use in Sweden. In 1796 he published an account of his experiments and inventions in the Swedish language, which in 1801 was translated into French and published at Paris, and was noticed in Nicholson's 'Journal' in 1803. A few years later Edelcrantz communicated a model of his telegraph to the English Society of Arts, in whose 'Transactions' for 1808 (vol. xxvi., pp. 184-189), it is minutely described. He commenced his experiments in September, 1794, with a machine resembling that first employed in France; but he soon abandoned it, and adopted a shutter-telegraph with ten boards or vanes, arranged in three vertical ranks, of which the centre one has four, and the others three boards each. By this arrangement 1024 changes or signals may be clearly shown; and it would be possible, by observing the *order* in which the shutters are exhibited, to show 4,037,912 changes. The minute attention required in this case would, however, occasion some uncertainty; and it is not likely that any circumstances could render so many changes at all desirable. Edelcrantz recommends that the vanes or shutters, which are represented as of a square form, should be painted black, and the frames which support them either white or red; and he says that the intervals between the shutters should be greater than their diameters. The apparatus for working the telegraph is ingenious, but too complicated for description here. It is sufficient to state that, when out of use, the shutters are held open by weights, and that the leverage afforded by the apparatus for closing them is such as to enable one man to hold them all, if necessary, against a high wind, which, it is added, could not be done with the English six-shutter telegraph, notwithstanding the smaller number of vanes, without employing several men. This inconvenience led Mr. Henry Ward, who had observed the difficulty of working the telegraph at Blandford, in Dorsetshire, to contrive an ingenious apparatus which is described in pages 207-8 of the same volume of the 'Transactions' of the Society of Arts as that which contains the communication of the Chevalier Edelcrantz. In this apparatus the grooved wheel or pulley which is fixed upon the axis of the shutter, to receive the rope by which it is turned, has the grooved portion of its rim formed in two segments, which are so attached to the periphery of the wheel by steel springs that they fly off and remain at a little distance from it when there is no strain on the rope; although, so soon as the rope is pulled, its pressure forces the segments into close contact with the solid rim of the wheel. In the segments are formed two notches, which, when the shutter is in either of its required positions, engage with a fixed catch so soon as the strain on the rope is relaxed, and so hold the shutter steady without any aid from the attendant. The pulling of the rope, by drawing the segments close to the wheel, releases the catch, and consequently enables the attendant to return the shutter to its original position. The ten-shutter telegraph of Edelcrantz had, at the date of his letter to the Society of Arts, been in constant use for twelve years, on both sides of the Baltic, and in other places in Sweden; 'chiefly in facilitating the communication of posts between Russia and Finland on one side (of the Baltic), and Sweden and England on the other.' He states that one person was sufficient for working it and making the observations, especially at the terminal stations; and that six signals were usually given in a minute.

Lieutenant-Colonel Macdonald, who greatly prefers the numerical to the spelling or lettering system, recommends a shutter-telegraph of still greater power, and consequently of greater complexity, than that of Edelcrantz. His terrestrial telegraph, the advantages of which he has pleaded at length in two treatises, published in 1808 and 1817, consists of thirteen shutters, arranged, like those of Edelcrantz, in three vertical sets, which represent, respectively, hundreds, tens, and units. As three boards in each set would only afford seven combinations for each column, he uses four, which give fifteen combinations, ten of which are used to express the numerals from 1 to 9, and 0, and the remaining five for abbreviations and arbitrary signals. The twelve ordinary boards are capable of producing 4095 distinct combinations, and the thirteenth, or auxiliary board, which is mounted over the centre of the machine, doubles that number. A flag or vane is added to the hundred side of the apparatus, to distinguish it in whatever direction it may be viewed, and a ball sliding upon the staff which supports it affords the means of again doubling the number; so that, in the whole, 16,380 distinct signs may be made with this machine. Macdonald recommends that the shutters be made about five feet square; in which case they may be seen with a moderate telescope, in clear weather, at a distance of ten or eleven miles.

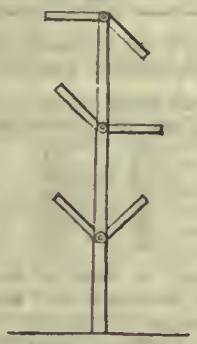
Although the shutter-telegraph was originally considered an improvement upon that of M. Chappe, which was so complex as to lead to considerable risk of error, unless it were worked by a practised person, experience has established the superiority of telegraphs or semaphores with moveable arms; and these have been greatly simplified, so as to avoid the objection raised to the old French telegraph. Among the schemes proposed soon after the first practical application of telegraphs, was one which consisted in dividing a large circle into twenty-four parts, for the letters of the alphabet, and employing a traversing radius, or index, to point them out; wires being fixed before the object-glass of the telescope to enable the distant observer to determine the position of the radius. This plan could only be applied to short distances, because refraction might render it difficult to distinguish between positions so little varying from each other. The same radiating principle was, however, adopted in some machines of more practical character; among which was a telegraph contrived by the Rev. J. Gamble (whose original shutter-telegraph has been before mentioned), consisting of five beams or arms pivoted at the top of a post, upon one axis, and capable of producing many different combinations without using angles of less than 45°. On a similar principle were constructed the French coast telegraphs adopted in 1803, to which the name of *semaphores* was first applied, and from which it has been given to other telegraphic machines, the action of which is dependant upon the motion of arms around pivots placed at or near their extremities. These French semaphores, or, as they were sometimes called, *signal-posts*, consisted of upright posts with two or three moveable arms, turning upon separate pivots, one above the other. Before they were much known in this country, Captain (now Major-General) Pasley had been led to observe the inferiority of the common land-telegraph to that used at sea, which consisted of coloured flags, and by which three numbers, or rather three numerals combined to form one number, might be readily expressed. To remedy this defect, he, in 1807 (before he had seen the French semaphore), devised what he termed a 'polygrammatic telegraph,' of which he published a description in the twenty-ninth volume of Tilloch's 'Philosophical Magazine.' This machine, which is represented in *Fig* 5, consisted of four posts, at

Fig. 5.



the top of each of which was pivoted a pair of arms. Each pair of arms was capable, by assuming the various positions indicated by the dotted lines added to the first pair, of forming more than a sufficient variety of distinct signals to express any of the numerals or the 0; and consequently the whole machine could represent any number composed of not more than four figures, besides having several signals to spare. In 1809 Captain Pasley saw the French semaphore, which he described in the following year, together with a modification of his own polygrammatic telegraph, founded upon it, in the thirty-fifth volume of the periodical just mentioned. This simplified polygrammatic telegraph, represented in *Fig.* 6,

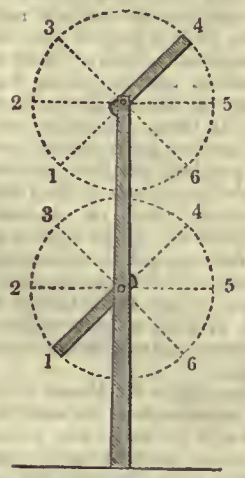
Fig. 6.



has three pairs of arms, representing hundreds, tens, and units, pivoted to different parts of the same vertical post. This contrivance is adopted by Lieutenant-Colonel Macdonald, with very trifling variation, in his 'Treatise explanatory of a new System of Naval, Military, and Political Telegraphic Communication,' published in 1817. By the addition of a ball and vane at the top of the mast, it becomes a machine of the same power as Macdonald's thirteen-shutter telegraph; as each pair of arms is capable of assuming fifteen distinct positions. Another semaphore on the same principle was submitted to the Society of Arts in 1821, by Lieutenant N. H. Nicolas, and described, together with a method of applying a shifting key to telegraphic communications, for the purpose of insuring their secrecy, in the thirty-ninth volume of the Society's 'Transactions;' where, although allusion is made, in a note, to the similar plan published by Colonel Macdonald, nothing is said of the earlier invention of Pasley. The telegraph of Lieutenant Nicolas consists of a lofty pole with four pairs of arms, one above another, the lowest pair representing units. For each of the three lower pairs of arms nine positions are all that are required, 0 being indicated by both arms being closed into the post, and therefore concealed from sight; but the upper pair are made to represent any number from 1 to 15, so that the total range of the machine is from 1 to 15,999.* This is effected by making the right arm represent 1, 2, or 3, according to its position as inclined upwards, extended horizontally, or inclined downwards; and assigning to the left arm the number 4 if inclined downwards, or 8 if extended horizontally. 5, 6, 7, and 9 are formed, respectively, by the combination of the signs for 4 and 1, 4 and 2, 4 and 3, and 8 and 1; and, in the case of the pair of arms which represent thousands, the left arm when inclined upwards indicates 12; and 10, 11, 13, 14, and 15 are produced by 8 and 2, 8 and 3, 12 and 1, 12 and 2, and 12 and 3, respectively. The telegraphs upon the commercial line of communication recently established between London and the Downs are constructed upon another modification of the polygrammatic principle; four pairs of arms being employed, but mounted upon two posts instead of one, as in the semaphore last described, or four, as in the original design of Captain Pasley.

In 1816 it was determined to change the Admiralty telegraphs into semaphores constructed on the principle of those used in France, with the improvements suggested by Sir Home Popham, who had previously done much for the improvement of naval signals. The action of Popham's semaphore is explained by *Fig.* 7, in which dotted lines are added to show the various positions in which the arms may be placed, and numerals to show the numbers indicated by those positions. Only two arms are employed; but as they are mounted upon separate pivots,

Fig. 7.



each of them can assume six different positions, and the two together are capable of affording forty-eight signals; which number, though less than that given by the six-shutter telegraph, is sufficient to express the letters of the alphabet and the Arabic numerals, and to leave thirteen signals unappropriated, for abbreviations and arbitrary signs. This kind of semaphore is still used at the government stations; and for the following table of its various changes or positions, and of the letters and numbers indicated by them, we are indebted to the article 'Telegraph,' in the seventh edition of the 'Encyclopædia Britannica,' by Sir John Barrow, one of the secretaries to the Admiralty.

Sir Home Popham's telegraph, in addition to its superiority in the important quality of simplicity, was a great improvement upon those which preceded it in the details of mechanical construction and in the mode of effecting the required movements. These are minutely detailed and illustrated with engravings, in the thirty-fourth volume of the 'Transactions' of the Society of Arts, in whose museum a model of the telegraph is deposited. The vertical post or beam is not a solid mass of timber, but a hollow hexagonal mast, which, turning on a pivot at its foot, and in a collar where it passes through the roof of the cabin used as an observatory, may be moved so as to display its signals in any direction. The moveable arms are provided with balance-weights in the form of masses of metal attached to their shorter ends, very near to the pivots upon which they turn, by which means they are enabled to move in any direction with the exertion of a very small force; and they

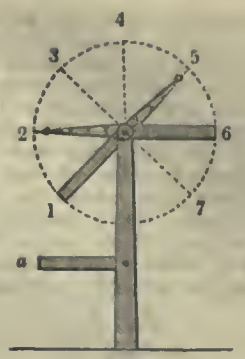
* 16,999 is the maximum number stated in the description of the machine; but this is probably a misprint for 15,999, as no means is described for producing the number 16, although it is easy to conceive how it might be done, if necessary.

are made, when out of use, to fall into grooves or recesses in the post, so as to become wholly invisible. The movements are effected by means of two winch-handles near the base of the mast, within the cabin, one for each arm. The winch-handles turn two small vertical bevil-wheels, which communicate motion by means of two horizontal bevil-wheels to long upright shafts or rods, which pass up the inside of the hollow post of the telegraph. At the upper ends of these rods, which are held steady by suitable bearings, are endless screws, which work into toothed wheels fixed upon the axes of the arms, and thereby communicate motion to them. In order that the person who works the machine may know precisely when the arms are brought to the required positions, similar endless screws are added near the lower ends of the vertical rods, to give motion by toothed wheels to indexes, which give a miniature representation of the motion of the arms. Excepting these indexes and the winch-handles, the whole apparatus is enclosed in the vertical shaft of the telegraph, on the outside of which small blocks may be added, to enable a person, with the assistance of a rope from the top of the post, to ascend the machine for the purpose of cleaning and oiling it.

About the same time Sir Home Popham proposed a modification of the semaphore for marine purposes, which, he conceived, would be found very advantageous for the merchant-service, by superseding the necessity for a costly set of signal-flags; the expense and wear and tear of which formed a serious objection to a system of general telegraphic communication at sea, excepting in the ships of the East India Company. His proposed sea-telegraph would not, it is stated, cost more than fifty shillings at first, and its wear and tear would not amount to five shillings a year. As the height of an apparatus resembling his land-semaphore would be objectionable for marine purposes, Popham proposed to use two posts twelve feet two inches high and six inches thick, each having a single arm six feet four inches long and ten inches broad, pivoted to the top, but not falling into a slot in the post, as in the last-described machine. In a small slot at the top of each post is a grooved pulley or sheave fixed upon the same axis as the arm; and at a convenient height from the bottom of each post another precisely similar pulley is mounted in like way, its axis passing through the post, and carrying a small wheel with four handles at right angles with each other, by which the machine is worked; the motion of the lower pulley being communicated to the upper one, and consequently to the arm, by an endless rope, which has two or three turns round each of the sheaves, and passes up by the sides of the post. When the telegraph is in use, the posts may be attached to the side of the vessel by stepping their lower ends into blocks fixed for the purpose, and lashing them to the bulwarks; or they may be mounted upon trucks, so as to be readily moved from one part of the ship to another. The description of this machine in Sir Home Popham's communication to the Society of Arts mentions but four positions for each arm, and states that when placed in the four positions diagonally to the post, one arm denotes 1, 2, 3, and 4, and the other 5, 6, 7, and 8. This arrangement gives twenty-four distinct signals, and avoids the possibility of mistaking the horizontal for an inclined position of either arm, of which there might, owing to the motion of the ship, be some risk.

Major-General Pasley, in a pamphlet published in 1823, entitled 'Description of the Universal Telegraph for Day and Night Signals,' states that, although he at one time considered Popham's arrangements to be judicious, he now deems the use of two separate pivots in the land-semaphore, and of two posts in that for marine use, unnecessary; and that, conceiving simplicity to be of more consequence than the power of making many changes or distinct signals, he has abandoned the polygrammatic principle, and adopted the simple form shown in the next cut, *Fig.* 8, which represents what he styles the 'universal telegraph,' as adapted for day-service. It consists of an upright post with two arms, both attached to one pivot at its upper extremity. Each arm is capable of assuming the seven positions indicated in the cut, besides what is called the *stop*, which is made when turned down and obscured by the post. Twenty-eight distinct signals may therefore be made by the apparatus, as shown in the subjoined table; these being more than sufficient for the letters of

Fig. 8.



the alphabet, though not numerous enough to allow of a full alphabet and the numeral characters.

Table of the separate or distinct Signals given by Pasley's Universal Telegraph.

1	6	15	25	36	56
2	7	16	26	37	57
3	12	17	27	45	67
4	13	23	34	46	
5	14	24	35	47	

It had been found, in using Sir Home Popham's ship-semaphores, that inconvenience and uncertainty was occasioned by the signals being sometimes seen in reverse, in which case one number or sign would be confounded with another; and this circumstance having been mentioned to Pasley by an officer in the navy, he provided against its occurrence with his universal telegraph by the addition of the auxiliary arm, or indicator, marked *a* in the cut, which, in whatever direction the machine may be viewed, distinguishes the side at which the numeral signs commence. It serves also to prevent the position marked 4 from being confounded with the stop, which it might be if there were nothing to indicate that the telegraph is at work, and to enable the eye to measure its height. The arms and indicator of this telegraph are framed and pannelled, for the sake of lightness, and the former move respectively before and behind the post; the indicator only turning up, by means of a rope from below, into a cavity in the shaft, like the arms of Popham's semaphore. The counterbalance weights of the arms are not fixed close to the pivot, but extend to some distance from it, in the form of a slender framework of iron, with a ball at the outer extremity, their light appearance rendering them almost invisible at a distance. The motions are effected by an endless chain or rope, with a contrivance for keeping it at the necessary degree of tension, as this plan is quicker in action than that of Popham; but Pasley observes that if, as in a ship-telegraph, a rope or strap be used instead of a chain, the index attached to the lower pulley must not be implicitly depended upon. In a subsequent part of his pamphlet he states that, in working with a rope, it is best to have the pulley-grooves of a triangular form, or with notches of the same form, cut into projecting cleats fixed to their circumference, in which case the turns of the rope round the pulleys may be dispensed with. A friend who was well acquainted with the effects of the climate of India, recommended to him that no iron should be used in semaphores to be exposed to it, and no wood, excepting for the post, which may be of teak, and for some additional parts required to convert the machine into a night-telegraph, for which bamboo may be used. The pannels of the arms should, in such a case, be made of thin sheet-copper, and the other parts of the machine of brass or bronze. Pasley states that telegraphs should in general be painted black, and, if possible, so placed that they may be seen without any background. If however a background be unavoidable, the telegraph should be of such a colour as to contrast with it. In some cases, where the appearance of the background varies much at different periods of the day, it has been found useful to paint the arms white and black, in large chequers, each occupying half of the width and half of the length of the arm.

The ingenious contrivances which have been suggested for effecting telegraphic communication are so very numerous, that anything like an enumeration of them is

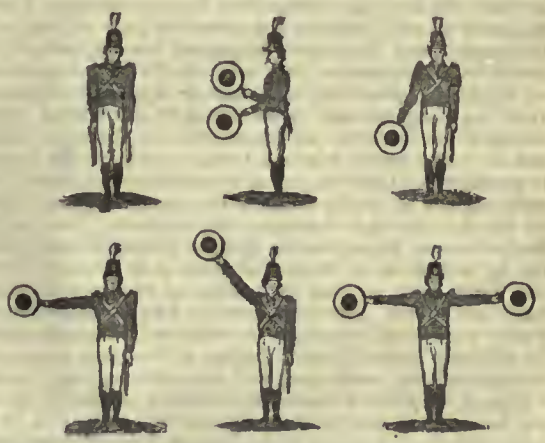
impossible in this place. Several depend upon the application of arms of various forms to a semaphoric telegraph. A two-armed telegraph, of which the two arms are differently shaped, would be capable of making twice as many signals as a two-armed telegraph with both arms of the same form; but, for ordinary purposes, such an arrangement would have many disadvantages. A machine of this character, contrived by Mr. Alexander Law, for both land and sea service, is described in the thirty-third volume of the 'Transactions' of the Society of Arts. Another class of telegraphic contrivances depend upon the exhibition of devices or symbols, in a manner somewhat resembling the original contrivance of Dr. Hooke. Of this sort Macdonald describes one under the name of the 'symbolic telegraph,' in which symbols resembling those of Hooke, but representing numerals instead of alphabetic characters, are dropped from three boxes or screens into as many open spaces, which have the values of hundreds, tens, and units respectively. An auxiliary shutter, a ball, and a vane or flag, as in his shutter-telegraph, serve to increase the powers of the machine at pleasure. Another contrivance, which, like the last mentioned, is well adapted for a portable telegraph for use in moderate distances, was invented about the year 1817 by Mr. Conolly, and described by him in a pamphlet published in that year, in English and French, entitled 'An Essay on universal Telegraphic Communication,' and also in the thirty-sixth volume of the 'Transactions' of the Society of Arts. Conolly's 'Portable Telegraph' consists simply of three square boards painted with simple devices in black and white, as shown in *Fig.* 9, the colours on one side being the reverse of those upon the other. The six figures in the upper row

Fig. 9.

are thus produced upon three boards, and each of these six figures is capable of producing four different signals, by turning each side of the board downwards in succession, as shown in the four devices at the lower part of the cut. Thus the three boards afford twenty-four distinct signals, which are sufficient for alphabetic communication; and one only is sufficient for making numerical communications, with the assistance of a smaller paddle-shaped board, the two sides of which, when it is used separately, denote affirmation or negation. In experiments made at Chatham, boards but eighteen inches square were found sufficient for a distance of two miles, with a telescope with a magnifying power of twenty-five; and Mr. Conolly had also, it is stated, exhibited these signals between Gros-nez and Sarque, a distance of seventeen miles, with boards twelve feet square. The day-telegraph of the Rev. James Bremner, alluded to in a previous column, consists of a frame-work with two circular openings, in each of which a semicircular screen or shutter revolving upon an axis in the centre of the circle, is capable of assuming four different positions. This machine expresses an alphabet of sixteen letters, by dividing the letters into four classes or sets of four each, and making one shutter express the class, and the other the number of the letter in that class. Major Charles Le Hardy communicated to the Society of Arts, in 1808, a telegraphic scheme of very different character to most that have been proposed. His telegraph consists of a large frame-work with nine radiating bars, representing the numerals from 1 to 9, and four sets of other bars intersecting them in such a manner as to form four concentric polygons (the whole apparatus having somewhat the appearance of a spider's web), which polygons express respectively units, tens, hundreds, and thousands; thousands being shown by the innermost polygon. Attached to the centre of the machine by pivots are four slender arms, carrying as many square boards of sufficient size to be visible at a distance; the respective lengths of these arms being such that the board of one may, during the revolution of the arm, traverse the polygon which represents thousands, that of another the hundreds polygon, &c. The action of the apparatus is as follows:—If it be desired to express the number 9202, the shortest arm is placed in such a position that its board may rest upon the radius 9, at the point where it is intersected by the thousands or innermost polygon; the next arm is turned to the radius 2, its board covering the point of intersection between it and the second, or hundreds polygon; the third arm and board is not called into action at all; and the fourth is, like the second, turned to the radius 2, the board covering the intersection between it and the outermost or units polygon. Thus far therefore the machine can express any number from 1 to 9999; but its power is increased by the addition of two other boards at the upper corners, one of which denotes 10,000, and the other 20,000, or, when displayed together, 30,000; so that the total range of the telegraph is from 1 to 39,999.

Several modes of telegraphic communication without machinery, or with nothing which cannot be conveniently carried by hand, have been devised, especially for the purpose of directing military operations, or of conveying speedy intelligence in time of war, where no line of ordinary telegraphs can be established. In 1808 such a plan, under the name of an 'anthropo-telegraph,' was laid before the Society of Arts by Mr. Knight Spencer, whose communication was printed in the twenty-seventh volume of their 'Transactions.' Mr. Spencer had observed, in the volunteer service, the inconvenience and loss of time occasioned in passing the orders of the commander-in-chief to the officers commanding distant divisions, when a great number of men were manœuvred together, and this led him to devise the plan alluded to, which he put in practice for the first time in 1805. His apparatus consisted simply of two circular discs of wicker-work, about eighteen inches in diameter, with handles six inches long, painted white, with a black circle or ball in the centre. As these did not weigh more than about a pound each, a man could easily hold them, one in each hand, in any required position. Standing in the position of the first figure in the subjoined cut, *Fig.* 10, with both discs held down and turned edgewise to the observer, the telegrapher indicated 'attention'; in the second position, he expressed a desire to convey intelligence to the correspondent at a distance; turning

Fig. 10.



one-quarter round again, and displaying one disk as shown by the third figure, he expressed the number 1; in the next position, 2; in the fifth, 3; 4, 5, and 6 were expressed by positions the reverse of 1, 2, and 3; the right-hand disk being held edgewise, and the other displayed; 7 was shown by displaying both discs in the lowest position; 8, as shown by the last figure in the cut, by both held out at arm's length; and 9, by both elevated; 0 was given by holding both discs above the head, one behind the other, so as to appear but one; and the signal of 'point' or 'period,' used at the close of every number, by placing the right hand disc in front of the breast, and the other behind the back, so that, like all the other signals, it might be seen both in front and rear. Another position, formed by displaying the right hand disc in the position 1 and the left hand disc in the position 6, formed a signal of 'error,' to be used in case of any mistake which might require the repetition of a signal. By this simple arrangement any

number might be readily expressed; and consequently it might be applied to any numerical dictionary whatever. Signals might also be made at night, by attaching reflector-lamps to the discs, in such a manner that they might hang vertically in every position of the discs, and strapping another lamp, glazed with green glass, upon the breast of the telegrapher. If intermediate stations be required, there must also be lamps upon the back of the man and of the discs. The difference of colour between the lamps upon the body of the telegrapher and those attached to the discs is essential to the distinct perception of some of the signals; and the difference between 'attention' and 'point' or 'period,' in nocturnal telegraphing, depends solely upon it. A letter from Admiral Hunter accompanies the description; in which, after expressing a very favourable opinion of the plan, he recommends enlarging the discs to two feet diameter, and painting one side as above described, and the other with a white centre and black rim, so that either might be used, according to the state of the weather.

In the volume from which the above details are taken, there is also an account of a yet simpler contrivance, invented by Lieutenant Spratt, for telegraphing by means of a white handkerchief, held in various positions to express the numeral characters and a few other convenient signs. The inventor employed this mode of communication some time before the battle of Trafalgar, as a means of carrying on conversation with a distant vessel; and he had used it successfully to converse between Spithead and the green ramparts at Portsmouth, &c. With a common telescope it may be used at a distance of four miles. Macdonald describes some more complicated contrivances of similar character, by the display of small flags, or of two white handkerchiefs and a black hat; by the latter of which plans between fifty and sixty distinct signals may be made. He also shows how signals may be made to any required extent by men changing their positions from sitting to standing, &c. Twelve men, arranged in three sets of four men each, may in this way be used instead of his large shutter-telegraph.

Some of the earliest methods of telegraphic communication which have been noticed above were essentially adapted for nocturnal use; but in modern times the use of night-signals has not been extensively required, although provision might have been made for their exhibition in connection with many day-telegraphs. Thus, for instance, it was proposed to add lamps to the moveable parts of Chappe's telegraph; and Edelcrantz suggested the application of lamps to his ten-shutter machine. In Davis's seven-shutter telegraph, previously described as applied to day-service, night-signals were to be given by a coloured lamp mounted in the centre of the seventh or sliding shutter, and six white lights attached to the outside of the frame, to produce, by their display or concealment by slides, the same signals as, under ordinary circumstances, are given by the opening and closing of the shutters. These side-lamps were to be secured to upright pieces of wood, sliding up and down in dovetailed grooves in the outside of the frame-work, so that they might be readily withdrawn when not in use. Provision is made for the adaptation of Pasley's universal telegraph to nocturnal communication by adding a central light at the top of the post, a lamp to the extremity of each arm, and an additional light as an indicator, suspended from a light derrick or crane projecting horizontally beyond the range of the arms, and on a level with the top of the post. This, the lamps themselves, and the additional counterweights required with them, should all be removed during the day. How little necessity there is, under ordinary circumstances, for the use of telegraphs by night, at any rate in connection with the navy, may be assumed from the statement of Sir John Barrow, that no attempt was ever made to add lamps to the six-shutter telegraphs formerly used by the Admiralty, notwithstanding the ease with which it might have been done. The semaphores now used by the Admiralty are also constructed without any provision for the display of night-signals. Macdonald's treatise (1817) contains several schemes for night-telegraphs, both for land and sea; one of which, consisting of three sets of four lights each, with an additional or director light to each set, has the same extensive powers as his favourite large shutter-telegraph.

Marine telegraphic communication is an object of even greater importance than that which has been principally treated of in this article, since there are many circumstances which render personal communication between vessels at sea impracticable, and that sometimes in cases of the greatest emergency. But, although naval signals have been, of necessity, long used, and flags of various forms and colours have been extensively employed for the purpose of making them, it was not till within a comparatively recent period that they were reduced to anything like an efficient telegraphic system. Sir John Barrow states (*Ency. Brit.*, art. 'Navy') that 'The idea of *numbering* the flags, and of assigning a certain number of corresponding sentences to certain combinations of these numbers, was reduced to something approaching a regular system in the fleet of Lord Howe;' and that in the year 1798 a new signal-book was issued by the Admiralty, the references to which were made by a numerical arrangement of flags. This book contained about four hundred sentences, expressive of the most usual operations of the fleet; but it was so imperfect that, if any order had to be transmitted which was not to be found in the dictionary, it became necessary to make the signal for 'a boat from each ship;' an order which could not always be complied with. This inconvenience was remedied by the plan, suggested by Sir Home Popham, of making the flag-signals represent the letters of the alphabet, as well as words and sentences, in connection with numbers. This individual also printed, at Calcutta, a new code of naval signals, which was subsequently reprinted in England, greatly extended, and adopted for use in the navy. Among the numerous improvements introduced by him is a new method of cutting the signal flags, so that, as he explained to the Society of Arts in 1816, 'the selvages of the buntin are brought on the outer edges of the flags, and the gorings in the centre; by which means the outer edge is susceptible of the least air of wind, and when the flag blows out, the gorings assist in keeping it out; whereas the old flags had a hem on the outside, which rendered them difficult to be moved without a fresh breeze, especially in damp and rainy weather, as the hem then became very heavy.' 'Besides,' he adds, 'it is impossible, from the nature of the buntin, to sew a straight seam, for the instant it is cut it will become in some degree curved.' (*Transactions*, vol. xxxiv., p. 174.) The only objection urged by Barrow to the code of naval signals now in use is one which is also applicable, more or less, to all that have been subsequently proposed, namely, the great number of flags, &c., required for making numerical signals to the extent laid down; which, in the code in question, amount to nine flags, five cornettes, five triangles, and five pendants. With such a number, he states, it is next to impossible, in calm weather, to make out the figure and colour of the flags; and equally so when, though expanded by the wind, the situation of the observer causes them to present only an edge towards the eye. He conceives that Popham's sea-telegraph, before described, is capable of entirely removing this difficulty; and that possibly Pasley's universal telegraph might be applied in like way with advantage.

The principle of the numerical system as applied to flag-telegraphs in the navy is briefly explained by Macdonald. Nine different variegated flags are employed to express the numerals 1 to 9, another for 0, and another, called a *substitute*, to repeat any flag under which it is hoisted, in case of the same numeral occurring twice in the number to be expressed. A pendant is also used in some cases as a substitute for the uppermost figure; and thus, by the use of eleven different flags and a pendant, any number from 1 to 999 may be expressed without displaying more than three flags, or two flags and a pendant, at once. In a telegraphic system devised by Mr. Conolly, and fully explained in the 'Transactions' of the Society of Arts for 1817 (vol. xxxv., pp. 205-208), flags are applied to express numbers in a different manner to the above. The basis of the system is an alphabetical list of the most necessary English words, arranged in a tabular form like the figures in the common multiplication table; the columns and horizontal lines being numbered. There are ninety-nine of each; and consequently the number of squares or divisions is 9801. The number of words is however greater, because in some cases, where no ambiguity is likely to be occasioned by it, the radical word and several of its modifications are placed in a single square or division of the table. The signals consist of twelve square flags (ten for the numerals and 0, a substitute, and a preparative signal), the same number of triangular flags, of

similar colours and devices, and a pendant; and any word contained in the table may be expressed by one or two square flags to indicate the number of the vertical column in which it occurs, and one or two triangular flags hoisted beneath them, to point out the horizontal column. In case of both the square and the triangular flag requiring to be doubled at once, instead of the two substitutes, the pendant is hoisted between them; and if it be necessary to spell any name or word not contained in the vocabulary, the twelfth triangular flag (answering to the square preparative signal) is hoisted to indicate that the twenty-four flags are to be taken for the letters of the alphabet, according to a preconcerted order.

We should not quit the subject of marine telegraphs without adverting to the very important advantages likely to accrue to the commercial shipping interest by the general adoption of a simple and uniform code of communication between vessels at sea, and from them to coast stations, or *vice versâ*. This desirable object is now being greatly promoted by the commercial telegraphic association superintended by Mr. B. L. Watson, whose signal books are, in future, by the direction of the Lords of the Admiralty, to be supplied to all the government vessels, in order that they may communicate with such merchant vessels using the code as they may meet with at sea. The whole code consists of thirteen flags, by which any message may be communicated from one vessel to another, or between a vessel at sea and any of the coast-stations established by the association at prominent points around the British islands. In connection with these coast-stations there are lines of semaphores from the Downs to London; from Holyhead to Liverpool; and from the Spurn to Hull; and from all of them communications are transmitted to a central office in London, and also to the owners or consignees of vessels entered in the telegraph list; for which privilege a subscription of twenty shillings per annum is paid to the association for each vessel. In like manner any message from the owners of a vessel, relative to change of destination, or otherwise, can be communicated from any station within sight of which she may pass.

Having now noticed the principal varieties of telegraphs which act by displaying signals visible at a distance, whether for use on land or at sea, it only remains, before alluding to contrivances of a different character, very briefly to touch upon a few points which bear upon telegraphic communications generally, but more especially upon land. The subject has been so ably treated by Sir John Barrow, in the article before alluded to, with the peculiar advantages derived from his connection with the Admiralty, that we cannot do better than condense some of his remarks on the comparative merits of different telegraphic systems. He observes that a telegraph employed for public purposes should be possessed of *power*, *certainty*, *simplicity*, *celerity*, and *secrecy*. It should have sufficient power to express, by distinct positions or combinations of moveable parts, any possible order or information, either by letters, words, or sentences. Its certainty will depend upon all its parts being clearly defined, wholly within the field of the telescope, and so distinct that there shall be no risk of mistaking one signal for another; whence the importance of simplicity becomes obvious. Bearing these points in mind, Barrow conceives that the choice will be found to lie between the six-shutter telegraph, Popham's semaphore, and Pasley's universal telegraph. Macdonald thinks that the arms of the semaphore are not so distinguishable even in clear weather, and not near so visible in cloudy weather, as the boards of a shutter-telegraph; but Barrow cites some observations of Mr. Gamble, which tend to a contrary result; making it appear that, owing to the confusion in the image on the retina, occasioned by the refraction of the atmosphere, the property which he terms *insulation* is generally more requisite than mere superficial magnitude, to give distinctness to a distant object. This point is illustrated by supposing a person to look at the letter I in the midst of a printed page, and to remove the paper from the eye until the image becomes indistinct from being confused with the surrounding letters; and observing how much more distinct the image would appear if the letter were printed alone upon a sheet of white paper. This question however does not rest upon mere theory or analogy; for it is stated that every officer upon the Admiralty line bears testimony to the superior distinctness of the semaphore at all times, and especially in cloudy weather. In order fully to decide the question, the shutter-telegraph at Nunhead, near New Cross, was left standing for some time on the same hill as the new semaphore; and the result of the trial for a whole winter was, 'that the semaphore was frequently distinctly visible when the boarded telegraph was so much enveloped in mist and fog that the particular boards shut or thrown open could not be distinguished;' and that the number of days in the course of the winter upon which the semaphore was visible exceeded those upon which the shutters could be seen by fully one-third. Even in the six-shutter telegraph one shutter was occasionally mistaken for another, and such accidents would doubtless have been more common had a more complicated shutter-telegraph, like that of Macdonald, been employed. The objection urged against the semaphore on the ground of the longer time taken to move the arms, because they describe arcs of larger circles than the boards of a shutter-telegraph, is hardly deserving of notice, as the difference (which may, Barrow says, amount to one second in each signal) is amply compensated by the greater facility of reading off. The semaphore has also the advantage in the greater simplicity of its machinery, which is much less liable to get out of order than that of the boarded telegraph.

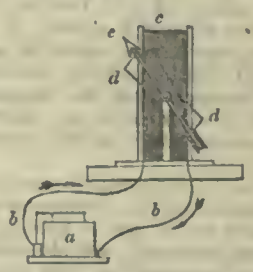
As shown by the tables given in the previous descriptions of the three machines particularly noticed by Barrow, the shutter-telegraph has the power of making a greater number of combinations without the use of the stop-signal (or signal which separates one word or one sentence from another) than either of the others, and Pasley's universal telegraph has the least power; but this is of little consequence, if the lowest power prove sufficient. Although the primary signals of the universal telegraph are only 28 in number, they may be increased to 784 by the use of two changes with one stop-signal between them (making three signals in the whole), or, by making three changes (four signals, with the stop), to 21,952; a number considerably exceeding the words and sentences in Sir Home Popham's telegraphic dictionary, which do not exceed 13,000. As this dictionary has never, it is affirmed, been found materially deficient in any of its divisions of subjects, it is evident that even when applied to communication by words and sentences instead of by letters, Pasley's simple telegraph affords sufficient power for all useful purposes; and further, that those who have extended their telegraphic dictionaries to very high numbers (Pasley mentions one extended to 140,000), have impaired their usefulness, owing to the difficulty and loss of time in finding the required sentence among so many. 'We have actually seen in one telegraphic dictionary,' observes Sir John Barrow, '120 pages, of three columns in each page, and sixty sentences in each column, containing upwards of 20,000 sentences (about one-third of the number of words in Johnson's dictionary), and each of these sentences beginning with the personal pronoun "He;" 20 pages with "If," &c.' 'Compared with the use of such a dictionary,' he proceeds to say, 'spelling the sentences is infinitely preferable as to certainty, and in many cases as to celerity. Indeed we should say that the abbreviated nature of communications made by telegraphs renders spelling by far the most eligible mode. In clear weather the rapidity of working single signals, the short compass within which any message may be condensed, the impossibility of committing any mistake that cannot be immediately rectified, more than compensate for the difference of a few minutes which the use of sentences may probably save. In cloudy or foggy weather, the latter method will always be liable to mistake. If experience may be assumed as a guide, the practice at the Admiralty of spelling all sentences, for the last thirty years, must decide in favour of that system.' In making communications alphabetically, much time may be saved by omitting non-essential words and letters, especially vowels. For example, the meaning of the sentence 'Order the Agamemnon out of harbour, and direct her to proceed to Spithead,' may be sufficiently expressed by 'Agmemn. to Spthed.' It is also important to condense the substance of the communication as much as possible into the former part of the message, so that no serious mistake may arise if the communication should be interrupted by foggy weather. Barrow relates a circumstance which occurred during the Peninsular war, in which some anxiety was occasioned by

the non-observance of this principle: n despatch from Plymouth to convey intelligence of a British victory hnving been commenced by the words 'Wellington defeated,' and then broken off by fog, which prevented the whole meaning, 'Wellington defeated the French nt,' &c., from being transmitted. Had the message run thus, 'French defeated at,' &c., the interruption of the despatch would have been of far less consequence.

Any means of telegraphic communication which depends upon the decipheriug of signals exlubited at a distant stntion is necessarily dependent upon contingencies of weather; but many plans have been contrived for effecting the object in such a manner as to be independent both of light and of the state of the atmosphere. For communication between the different parts of a house this object may be effected by a mechanical connection, by chains or wires, between two dials with revolving indexes or pointers, in such a way that when one pointer is directed to a particular letter or word inscribed upon the dial to which it is attached, the other may exhibit n similar movement. The attention of the servant is engaged previously by ringing a bell; and when the required signal has been made, a spring returns both indexes to their original position. Such a plan, though very useful for domestic purposes, is not adapted for distant communication. Speaking-pipes, or tubes to convey the voice from one place to another, nre also available for short distances, but their range is too limited for application on an extended scale. One of the early schemes of this character depends upon the principle of water always finding its level; but, independent of the difficulty which might arise from the friction of wnter in a very long pipe of small diameter, such as would be required to connect the vertical tubes in which the observations would be made, such a plan involves the necessity of having all the communicating stations at or near the same level. Other hydraulic telegraphs depend upon the incompressibility of water or other liquids; it being proposed to lay down small pipes of any required length, and to indicate different signals by pressing more or less upon the surface of the fluid contained in them, which would, it is supposed, transmit the motion to the opposite end of the pipe, where it might be pointed out upon a dial, or in any other convenient manner. Mr. Vallance described such a method of telegraphic communication in a pamphlet, published in 1825, of which Hebert gives some account (*Engineer's and Mechanic's Encyclopædia*, vol. ii., pp. 767-8); and some similar schemes have been more recently propounded. Air confined in small pipes has also been tried to a limited extent as a pneumatic telegraph; but in this, as well as in the hydraulic system, the risk of leakage is a serious disadvantage. The application of electricity to telegraphic communication is attended with fewer difficulties, and has recently been carried into effect on an important scale by Messrs. Wheatstone nnd Cooke. The possibility of so applying it was conceived by several persons long before it was attempted on a practical scale. Arthur Young, who visited France in 1787, 1788, and 1789, mentions, in his travels, the experiments of M. Lomond, who was able by means of electricity to convey messages from one room to another; and the Rev. Mr. Gamble, in his description of his original shutter-telegraph, alludes to the project of electrical communication. Mr. Francis Ronalds, in a pamphlet on this subject, published in 1823, states that Cavallo proposed to convey intelligence by passing given numbers of sparks through an insulated wire; and that, in 1816, he had himself tried experiments upon this principle, which he deemed more promising than the application of galvanic or voltaic electricity, which had been projected by some Germans and Americans. He succeeded perfectly in transmitting signals through a length of eight miles of insulated wire; and he describes minutely the contrivances necessary for adapting the principle to telegraphic communication.

It is however to the joint labours of Messrs. W. F. Cooke and Professor Wheatstone that electric telegraphs owe their practical application; and in a statement of the facts respecting their relative positions in connection with the invention, drawn up at their request by Sir M. I. Brunel and Professor Daniell, it is observed that 'Mr. Cooke is entitled to stand alone, as the gentleman to whom this country is indebted for having practically introduced and carried out the electric telegraph as a useful undertaking, promising to be a work of national importance; and Professor Wheatstone is acknowledged as the scientific man whose profound and successful researches had already prepared the public to receive it as a project capable of practical application.' Their telegraph, which was patented in 1837, acts upon principles founded on Oërsted's celebrated discovery, that a magnetic or compass needle may, through the agency of a voltaic current, be invested with an artificial polarity. [ELECTRO-MAGNETISM, vol. ix., p. 342.] 'Thus,' explains Mr. Cooke (*Telegraphic Railways*, p. 14), 'as a natural stream of electricity passing round the circumference of the earth causes magnetic needles in general to be deflected at right angles to its course, or towards the north and south poles, so an artificial stream of electricity of adequnte strength will cause magnetic needles placed within its influence to be similarly deflected at right angles to *its* course, whatever that mny be. If then a magnetic needle were placed parallel and near to any part of n conducting wire, which we will suppose to be laid down between London and Blackwall, the transmission of an electric current from a voltaic battery would cause the needle to change its position, so as to stand during the continuance of the current at right angles to the wire, being turned in one direction or the other according to the course of the current. If this deflexion of the needle were limited by two fixed stops placed respectively at the two sides of one of its poles, the motion of thnt pole to one stop might evidently constitute one signal, nnd its motion to the other stop another signal.' Such an apparatus is shown in *Fig.* 11, the dial upon which the signals are represented being removed. In this cut *a*

Fig. 11.



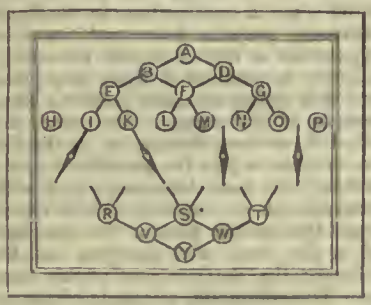
may be supposed to represent the battery, and *b b* the conducting wire, which is formed behind the dial into a coil *c*: *d d* is the magnet, which is mounted upon an axis passing through the coil, and carrying upon its extremity, which comes through the dial, an index or pointer *e*. The arrows indicate the direction of the current required to deflect the magnet to the position indicated in the figure; and a current in the opposite direction would produce n deflexion towards the opposite side. While no current passes through the wire, the magnet and pointer remain vertical. The next cut (*Fig.* 12) represents three such in-

Fig. 12.

struments complete, and connected together by wires enclosed in tubes, which may be of any required length. One of these may be supposed to be at the Minories, the next at an intermediate station, and the third at Blackwall; and as each is provided with a battery, and a handle (beneath the dial) by which the conducting wire may be connected with it at pleasure, the attendant at every station at which such an instrument is placed cnn instantaneously communicate the signal to 'stop' or to 'go on' to all the other stations; attention being previously engaged by ringing a bell, placed above the dial, by an ingenious application of the voltaic current. By this beautifully simple apparatus the peculiar method of working the trains upon the Blackwall railway [RAILWAY, vol. xix.,

p. 260] is effected with the greatest ease, although it is essential that the attendants at each terminus should know not only when the train is ready to start from the opposite end of the line, but also when the carriages at the five intermediate stations are ready. In stopping the trains the same precise information is required; and it is of vital importance in case of any casualty to the rope or to any of the carriages. It is perhaps not too much to say that the mode of working adopted on this railway would be impracticable without the aid of the electric telegraph. Some telegraphs of more extensive powers than the above are in use on the Blackwall railway, as well as on the Great Western and Edinburgh and Glasgow lines. *Fig.* 13, which represents a dial like that on the Great Western Railway, shows how, by the combination of four such magnets and pointers as are described above, all the letters of the alphabet may be expressed, by pointing one or two

Fig. 13.



needles towards them; and of course a larger or smaller number of signals might be made on the same principle if necessary. A telegraph with two pointers, showing eight signals, is considered by Mr. Cooke to be sufficient for all ordinary purposes. The wires, where several are used, are combined into a rope and enclosed in an iron tube, which may be either buried beneath the surface of the earth or supported above it; and they are insulated from each other by wrapping them round separately with a mixture of cotton and caoutchouc. For details of construction as applied to various purposes, and for an exposition of the great advantages derivable from the use of the electro-magnetic telegraph, especially in connection with railways, we must refer to the publications of Mr. Cooke, the 'Reports of the Select Committee of the House of Commons on Railway Communication' in 1840; and the 'Railway Times' for June 12, 1841. The longest continuous line yet completed is that from Paddington to West Drayton, about thirteen miles; but this has been so arranged for the purpose of experiment as to be equal to a stage of thirty-nine miles. It is reported (July, 1842) that an electric telegraph is about to be laid down along the South-Western Railway, from London to Gosport.

TELE'MACHUS (Τηλέμαχος), the son of Odysseus (Ulysses) and Penelope. When his father joined the Greeks in their expedition against Troy, Telemachus was very young, but during his father's absence he grew up to manhood. When the gods had decreed that Odysseus should return home from the island of Ogygia, Athena (Minerva), assuming the appearance of Mentes, king of the Taphians, appeared to Telemachus, and advised him to get rid of the suitors of his mother; but if Penelope should wish to marry again, to send her to her father's house, that she might celebrate her nuptials there. She also advised him to sail to Pylos and Sparta, to see whether he could learn anything concerning his father, who, as she said, was probably still living in some island where he was forcibly detained; but if he should be dead, she enjoined Telemachus to raise a monument to his memory, and to rid himself of the suitors of his mother either by stratagem or by force. Telemachus obeyed the commands of the goddess, and visited Nestor at Pylos and Menelaus at Sparta. Both of them received him hospitably, and Menelaus communicated to him the prophecy of Proteus about his father. In the meantime Odysseus arrived in Ithaca, and lodged with Eumaeus, the swineherd, in the disguise of a beggar. In this condition he was found by Telemachus, who, by the advice of Athena, had also returned to Ithaca. The father made himself known to his son, and the two devised a plan for getting rid of the suitors. They went to the town, and Odysseus was admitted as a beggar to a feast of Telemachus and the suitors. When the suitors began to insult the poor man, a fight ensued, in which Odysseus and Telemachus killed the suitors. Telemachus then accompanied his father to the aged Laertius. Thus far the story is described in the Odyssey. Later writers mention other incidents connected with the story of Telemachus, especially relating to his marriage, which however is told in different ways. According to one tradition, he married Circe or her daughter Cassiphone, and he had a daughter Roma, whom he gave in marriage to Aeneas. Servius (*ad Aeneid.*, x. 167) calls him the founder of the town of Clusium in Etruria.

In modern times the name of Telemachus has acquired celebrity from the moral romance of Fénélon, which is based upon the story in the Odyssey. [FENELON.]

TELEMANN, GEORG PHILIPP, a name of no mean rank in musical history, therefore entitled to some notice here, was son of the minister of the Lutheran church at Magdeburg, and there had his birth, in 1681. Though educated with other views, his predilection for music was too strong to be combated, and it became his profession. He successively held many appointments in Germany, the chief of which was that of composer to the Lyric theatre at Hamburg, for which he produced no less than thirty-five operas. But these were only a small part of his labours: he is said to have exceeded the prolific Alessandro Scarlatti in the number of his works for the church and the chamber; and, in 1740, his overtures on the model of Lulli amounted, Doctor Burney tells us, to six hundred! Strange however as it may appear, yet it is most true that of this almost incredible number of compositions, only two or three fugues are now known, at least in England, and these only to a very few organists of patient and deep research.

Telemann was a fellow student of Handel, and attained considerable longevity, having died in 1767, at the age of 86. He was twice married, and each wife had ten children; and it is remarkable that not one of them manifested the slightest inclination for the art to which their father owed his fortune and repute.

TELEOSA'URUS. Since the article CROCODILE was written, Professor Owen has published his valuable *Report on British Fossil Reptiles*, in which he notices, among others, a family of extinct crocodilians characterized by a combination of a bi-concave structure of the vertebræ with long, narrow jaws, armed with slender, conical, sharp-pointed, and equal teeth, adapted, like those of the existing Gavials, for the seizure and destruction of fishes. Professor Owen makes this family consist of two genera, whose characters mainly rest on the difference of position in the external nostril. In the first of these, *Teleosaurus*, the external nostril is terminal and placed at the extremity of the upper jaw; in the other, *Steneosaurus*, this aperture is a little behind and above the termination of the upper jaw.

Geological Distribution and Habits of the Family.—The *Teleosauri* and *Steneosauri* are confined to the oolitic division of the secondary rocks. At this period there were scarcely any mammals, but fishes were abundant, and Professor Owen refers to the just observation of Dr. Buckland in his *Bridgewater Treatise*, that it might, *à priori*, have been expected that if any crocodilian forms had then existed, they would most nearly have resembled the modern Gavial. Professor Owen goes on to remark that the modification in the structure of the vertebral column, and the complete mail of imbricated bony scutes, characteristic of the species, indicate that the habits of the antient *Teleosauri* and *Steneosauri* were more strictly marine than those of the modern Gavials, and that their powers of swimming, of pursuing and overtaking their aquatic prey, were greater.

After noticing the papers of Messrs. Wooller and Chapman, in two separate communications in *Phil. Trans.*, vol. 50, 1758, and the figures of an incomplete skeleton

there given, as one of the earliest evidences of antient reptiles which is recorded in a scientific publication, and observing that, notwithstanding the remark of Captain Chapman, that 'it seems to have been an alligator,' and of Mr. Wooller, that 'it resembles in every respect the Gangetic Gavial,' Camper pronounced it to be a whale, meaning perhaps a dolphin; an opinion adopted by Faujas, who went a step further, and referred it to the genus *Physeter*, Professor Owen points out Cuvier's refutation of Faujas in the first edition of the *Ossemens Fossiles*, and his declaration in the same work that it was in truth a crocodile. The Professor adds, that Cuvier's subsequent analysis led him (in 1812) to the conclusion that it belonged to the genus of Crocodiles, and was most probably identical in species with the crocodile of Honfleur.

But although the opinions of Messrs. Wooller and Chapman came much nearer to the truth than those of Camper and Faujas, they were still distant from it; and Professor Owen proceeds to show that the fossil really differs more from the Gavial than the Gavial does from any other existing Crocodilian.

Pursuing his inquiry, Professor Owen remarks, that in 1836, when so many new and singular genera, allied to the Crocodilian family, had been added to the catalogues of palæontology, by the labours of English anatomists and geologists principally, Cuvier expresses his opinion with more caution. Cuvier *then* says, 'It now remains to be known whether it is a crocodile, or one of those new genera discovered in the same beds. The bones of the extremities are too incomplete, and the head is not represented with sufficient details, to decide the question; but the vertebræ appear to me to be longer, in relation to their diameter, than in the new genera, and, in this character, more like those of Crocodiles. Those alone who shall rediscover the original, if it still exists, will be able to inform us whether the other characters respond to those referred to.'

Professor Owen inquired at the British Museum, to which the collections formerly belonging to the Royal Society of London were transferred, but he states that no specimen corresponding with the account and figures given by Messrs. Wooller and Chapman exists in that museum.

But a second specimen of a Crocodilian with a long and slender nose was procured from the lias near Whitby (between Staithe and Runswick) in 1791, and a more perfect skeleton was obtained from the alum-shale of the lias formation at Saltwick, near Whitby, in 1824. Professor Owen states that both these specimens so closely resemble the older fossil in all the points in which a comparison can be established, as to dissipate the remaining doubts as to the nature and affinities of the specimen from the same locality described in *Phil. Trans.*, 1758. He then refers to the figures of the skeleton discovered in 1824, in Young and Bird's *Geological Survey of the Yorkshire Coast*, and in Dr. Buckland's *Bridgewater Treatise* [CROCODILE, vol. viii., p. 169], observing that it is now preserved in the museum at Whitby, where he closely examined it. 'In this specimen,' says the Professor, 'are preserved the cranium, wanting the snout, the whole vertebral column, the ribs, and the principal parts of the four extremities, together with the dorsal and part of the ventral series of dermal bones. The entire length of the skeleton, following the curvature of the spine, is fifteen feet six inches, to which may be added two feet six inches for the lost snout. The cranium posteriorly is broad, depressed, and square-shaped: it begins to contract anterior to the orbits, and gradually assumes the form of the narrow depressed snout; the converging sides of the maxillæ are concave outwardly. The zygomatic spaces are quadrilateral, longer in the axis of the skull than transversely; the orbits are subcircular; they look upwards and slightly outwards; their margins are not raised, and their interspace is slightly concave. The parietal bone is relatively longer than in the Gavial, and sends up a longitudinal median crest, from the posterior part of which a strong process extends on each side outwards, and curves slightly backwards parallel with the ex-occipitals, to join the mastoid and tympanic bones, the latter of which expands as it descends to form the joint for the lower jaw.'

Professor Owen then gives details of the dimensions, from which he calculates that the entire length of the skull must have exceeded 4 feet 6 inches. He states that the cranium of one of the Caen Teleosauri measures 3 feet 4 inches, whence Cuvier calculates the entire length of the animal at near 15 feet. Professor Owen remarks that the Whitby Teleosaur agrees with the Caen species, and differs from the Gavial in the following particulars:—the anterior frontal bone is less extended upon the cheek; the lacrymal is much more extended, and is larger at its base; and the jugal bone is more slender. The posterior frontal bone, which separates the temporal from the orbital cavities, is much longer and narrower. 'The parietal and occipital crests each form a thin trenchant plate, and are not flattened above. The mastoidean angle is not uninterruptedly united with the back part of the articular process of the tympanic; it is separated from it by a large depression, which is overarched by a trenchant crest belonging to the ex-occipital. The mastoidean bone has a concavity at its descending part, of which there is no trace in the Gavial. The indentation between the articular process of the tympanic and the tuberosity of the basi-occipital is much smaller than in the Gavial, and the basilar tuberosity projects downwards in a less degree. The pterygoid ala is not expanded externally, as in all crocodiles, but is contracted by a large fissure at the part where it is going to unite itself to the bone; the orbital margin of the malar is not raised, and does not leave behind it a deep fissure, as in the Gavial. The malar does not rise to join the posterior frontal bone; but, on the contrary, the frontal descends to join the malar at the external margin of the orbit. The vacuity between the orbit and the anterior part of the tympanum is much elongated in the fossil, and occupies four-fifths of the temporal fossa; the anterior part of this fossa is narrow and acute. The columella, or ossicle of the ear, is cylindrical, and much larger in proportion than in any known crocodile or other reptile.

'Cuvier calculates the number of teeth in the *Teleosaurus Cadomensis* to be 180, viz. $\frac{45-45}{45-45}$. The *Teleosaurus Chapmanni* has at least 140 teeth. The Gavial has 112, or $\frac{28-28}{28-28}$. The teeth of the Whitby Teleosaur are as slender and sharp-pointed, but not so compressed as in the Gavial; they correspond with those of the Caen Teleosaur, and equally illustrate the dental characters usually attributed to the present extinct genus.'

Professor Owen then shows that the Whitby Teleosaur differs from the Caen Teleosaur, as does the Monheim Teleosaur (*Crocodilus priscus*, Soemmering), in having the upper temporal fossa longer in proportion to their breadth, and that it also differs from the Teleosaurs of both Caen and Monheim in the more equal size of the teeth, and from that of Monheim in the greater number of teeth, the *Teleosaurus priscus* having at most $\frac{27-27}{26-26} = 106$. He also points out other differences.

In treating of the *vertebral column*, the author states that the number of vertebræ in the true crocodiles of the present period rarely exceeds sixty, the number assigned by Ælian to the crocodile of the Nile. Cuvier, he observes, generally found 7 cervical, 12 dorsal, 5 lumbar, 2 sacral, and 34 caudal vertebræ. In the *Crocodilus acutus*, he remarks, a thirteenth pair of ribs is occasionally developed, and, according to Plumier, the last-mentioned species has two additional caudal vertebræ; the alligator (*Alligator Lucius*) [CROCODILE, vol viii., p. 163] has 68, the additional ones being in the caudal region; the Gavial has 67 vertebræ, viz. 7 cervical, 13 dorsal, 4 lumbar, 2 sacral, and 41 caudal.

'The very perfect specimen in the Whitby Museum,' says Professor Owen, 'displays the number of the vertebræ through the whole spinal column, and establishes another difference between the Teleosaur and the Gavial, the former having a number of vertebræ intermediate between the Crocodiles and Gavials, viz. 64, with a special peculiarity in the excess of costal vertebræ, as the following formula indicates, viz., 7 cervical, 16 dorsal, 3 lumbar, 2 sacral, 36 caudal. In all subgenera of existing crocodiles, as in the extinct tertiary species, the hind surface of the vertebra is convex, the fore surface concave, except in the atlas and two sacral vertebræ. Cuvier, who had the opportunity of seeing only the annular part (neurapophyses) of the cervical vertebræ of the Caen

Teleosaur, regrets his inability to state whether either of the articular extremities of the centrum were convex, or which of them. The Whitby Teleosaur decides this question, and shows that both articular extremities of the vertebræ are slightly concave in the cervical as in the rest of the vertebral series. The atlas in the Teleosaur corresponds essentially with that of the crocodiles, as is shown by the three main component parts of this bone, from a Whitby Teleosaur in Lord Enniskillen's collection. The body or centrum is a transverse quadrilateral piece, smooth and convex below, narrowing like an inverted wedge above, with articular facets, viz.: a concavity in front for the occipital condyle; a flat rougher surface on each side of the upper part for the attachment of the neurapophyses; a posterior facet for the anterior part of the detached odontoid element of the axis; and the small surface on each lateral posterior and inferior angle, for the atlantal ribs. The neurapophyses are pyramidal processes, with their apices curved towards each other; they are relatively smaller in proportion to the centrum than in the crocodile. The general anterior concavity for the reception of the occipital tubercle is formed at its circumference by the centrum and neurapophyses of the atlas, and at its middle by the anterior detached odontoid epiphysis of the axis, which is here evidently the analogue of the so-called atlas in the *Ichthyosaurus*, the true body of the atlas in the Teleosaur representing the first inverted wedge-shaped bone in the Ichthyosaur. The spine of the atlas is a large oblong piece articulated with the neurapophyses of the atlas, and partly overlapping those of the axis.'

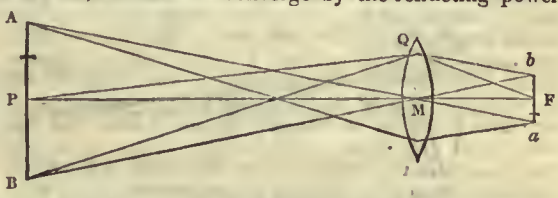
The Professor then describes in detail the cervical vertebræ, from which it appears that the same mechanism for fixing and strengthening the neck, as is found in existing species, exists in the ancient marine crocodiles; the vertebræ of the dorsal region, with 16 pairs of ribs, a greater number than occurs in any existing Crocodilian; a posterior dorsal or lumbar vertebra, which faintly indicates one of the most striking characters of the vertebræ of Streptospondylus; and the caudal vertebræ, which progressively diminish in every diameter, save length, from the middle to near the end of the tail, the terminal vertebræ being shorter than the rest. The sternum and sternal ribs, he remarks, closely agree with the ordinary Crocodilian type. He had not seen a specimen of the abdominal sternal ribs.

Professor Owen then notices the structure of the *Pectoral and Pelvic Extremities*, as compared with those of existing Crocodiles, and the *Dermal armour*, the bony dermal scutes of which are regularly disposed in the Teleosaur, as in them; but the scutes of *Teleosaurus Chapmanni*, he observes, differ as much from those of the existing Gavials and Crocodiles, as those of *Teleosaurus Cadomensis* do. The following are the species recorded by the Professor:—*Teleosaurus Chapmanni*; *Teleosaurus Cadomensis*; *Teleosaurus Cadomensis*, var.; and *Teleosaurus asthenodeirus*, Owen. [Steneosaurus; Crocodile, vol. viii., p. 168.]

TELESCOPE (from the Greek *teléscopos*, τηλεσκόπος, 'far-seeing'), an optical instrument consisting of a tube which contains a system of glass lenses having all their centres in one common axis, or a tube containing a metallic speculum in combination with such lenses: by either kind of instrument distant objects are caused to appear magnified, and more distinct than when viewed by the naked eye. Those which are constructed with glass lenses only are called dioptric, or refracting, and the others catoptric, or reflecting telescopes. In the former kind the rays in the pencils of light which come from every part of the object viewed are, by the first lens on which they are incident, made to converge so as to form an image at the focus of the lens. In some cases the rays in each pencil are intercepted by a second lens, and, by its refractive power, are made to enter the eye in parallel directions: in other cases, the rays, after having crossed each other at the place where the image is formed, fall in a divergent state upon a second lens, and by it are refracted so as to emerge from it in parallel directions. Frequently however the parallelism of the rays is effected by two or more lenses in addition to that, called the object-glass, by which the image was formed. In reflecting telescopes an image is formed by the reflection of the rays in the pencils of light coming from the object, after having impinged upon the concave surface of the speculum: in some cases this image is viewed through one glass lens or more, but frequently the rays, before or after forming the image, are reflected from a second mirror, and are subsequently transmitted to the eye through lenses.

By these instruments objects even in the remotest depths of space are rendered accessible to human vision; and terrestrial objects faintly visible in the distance are brought, as it were, close to the eye. In the hands of astronomers they were the means, almost immediately on being invented, of making more discoveries in the heavens than had been made during 5000 years previously; they form a valuable addition to the instruments employed by the mariner and the surveyor, and they will ever constitute the most agreeable companion of the traveller, by enabling him to distinguish, in every direction from him, objects which it might be difficult or impossible for him to approach.

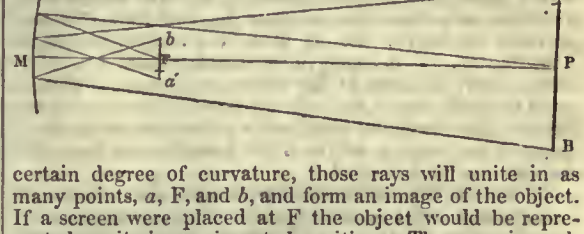
In exhibiting the principles on which a telescope is constructed, it will be proper to commence with an explanation of the means by which the image of an object is formed at the focus of a lens or of a reflecting mirror. With respect to a lens, if it be of the kind called convex [Lens], the rays in the pencils of light which proceed from every part of an object, as APB, in passing through the lens, supposing the latter to have a proper degree of curvature, are made to converge by the refracting power



of the glass at points, as *a*, F, and *b*, and the assemblage of such points constitutes an image of the object: if a screen were placed at F perpendicularly to the axis PF, the object would be represented on it, in an inverted position.

If the lens were of a concave form, the rays in the several pencils, after passing through it, would be made to diverge from one another, and consequently no image could be formed: yet if the directions of the rays, after refraction, were produced backwards, they would unite between the lens and the object, in points corresponding to those which constitute the image formed by the convex lens.

If the rays in the pencils of light proceeding from different points, A, P, B, in an object are reflected from the surface of a concave mirror, supposing the latter to have a



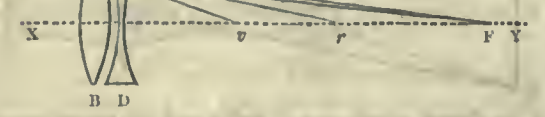
certain degree of curvature, those rays will unite in as many points, *a*, F, and *b*, and form an image of the object. If a screen were placed at F the object would be represented on it, in an inverted position. The rays in each pencil reflected from the surface of a convex mirror are made to diverge from each other; and in that case no image is formed.

Now, if the object AB be so remote that, in each pencil, the rays incident upon a lens may be considered as parallel to one another, the point F is called the principal focus; and in the article Lens (p. 421, col. 2) there will be found a collection of formulæ for the reciprocals of the focal lengths of lenses of all the different kinds; it being understood that the diameter of the lens is small, which is generally the case with telescopes, and that the light is homogeneous. But, since all light is not of one kind, and a lens acts like a prism in causing, in each pencil, the rays of the differently coloured light to diverge from one another: it follows that each of the coloured lights will form its own image at its proper focus; and the image formed by light of one kind being seen by the eye along with the images formed by light of the other kinds, the representation of an object when formed by a single lens

appears to be indistinct and surrounded by a coloured fringe. [Achromatics; Dispersion.] It may be observed that the principal focus of any lens, with respect to each colour, may be obtained from the formulæ in Lens by substituting in them the value of μ (the index of refraction) for the given kind of light.

Thus, in an optical instrument, in addition to the distortion of the image arising from the sphericity of the lens, there is an indistinctness caused by the dispersion of the different colour-making rays; and, in a good telescope, it is requisite that both of these imperfections should as far as possible be removed. The chromatic aberration, as the dispersion of the colour is called, constitutes by far the greater evil of the two, for Newton has shown that it exceeds the former nearly in the ratio of 5449 to 1; but fortunately it is that which, to an extent sufficient for practical purposes, admits of being easily corrected.

Since different kinds of glass have different degrees of dispersive power, it is evident that the chromatic aberration may be diminished, if not wholly removed, by causing the light to pass through two lenses of different kinds of glass, and of such forms that they may refract the rays in each pencil in opposite directions. The object-glass of a telescope when so formed is said to be *achromatic*, and the manner in which the effect is produced may be understood from the following description. Let PQ be the direction of a pencil of compound light incident on the



first surface of the convex lens AB, in a direction parallel to the common axis, XY, of the two lenses. By the refractive power of this lens (crown glass) the red rays in the pencil would, if no object were interposed, proceed in the direction Q*b*, meeting XY in *r*, and the violet ray in the pencil would proceed in the direction Q*c*, meeting the axis in *v*. But the refractive power of the concave lens CD (flint glass) acts, from its form, in a direction contrary to that of the convex lens, causing the rays either to diverge from the axis XY, or to meet it in points beyond *v* and *r*, towards Y: suppose the curvature of this lens to be such that the red rays in the pencil PQ would, after refraction in both lenses, meet the axis in F (the ray Q*br* taking the direction *b*F); then the dispersive power of this kind of glass exceeding that of the other kind, the violet rays in the refracted pencil will tend farther away from the axis than the red rays do, and thus will tend towards the latter; the ray Q*cv*, for example, taking the direction *c*F. It is conceivable, therefore, that the curvatures of the surfaces of the lenses may be such that, in each incident pencil, the red and violet rays (the extreme rays of the spectrum) shall after refraction unite at the place of the image; and thus the fringe due to these two colours may be destroyed.

If the two kinds of glass dispersed the different colour-making rays in the same proportions, their contrary refractions would cause all the colours to be united on the image formed at F: no two kinds of glass have however been as yet discovered which possess this property; and therefore the red and violet images only are united: fortunately in uniting the extreme rays of the spectrum, the others are brought so near together, that for ordinary purposes the image is as free from colour as can be desired.

From the description just given it will be evident that the place F, of an image in which the dispersion of the red and violet rays is corrected, may be determined on obtaining, from the common theorems of optics, algebraic expressions for the focal lengths of the compound lens for each of those kinds of light, and making the expressions equal to one another. Thus, supposing R and S to be the radii of the curve surfaces of a double convex lens of crown glass, and μ the index of refraction for light of one kind (red, for example); supposing again that the rays in the pencils of incident light are parallel to one another and pass through the lens very near the axis; then, by a fundamental theorem in optics we have, F being the distance from the focus to the lens, which is moreover without thickness,

$$F = \frac{R.S}{R+S} \cdot \frac{1}{\mu-1};$$

but since, in the present case, the lens may be supposed to be isosceles (R=S), we have $F = \frac{R}{2(\mu-1)}$.

In like manner the focal length F′, of a double concave lens of flint glass, R′ being the radius of each surface, and μ' the index of refraction for red rays, is equal to $-\frac{R'}{2(\mu'-1)}$, the rays being incident near the axis.

Hence, by a fundamental theorem in optics,

$$\frac{R'}{\mu'-1} - \frac{R}{\mu-1} : \frac{R'}{\mu'-1} :: \frac{R}{2\mu-1)} : \frac{RR'}{2\{R'(\mu-1)-R(\mu'-1)\}}$$

and this last term is the focal length of the compound lens for red rays. Its reciprocal is equal to $\frac{2(\mu-1)}{R} - \frac{2(\mu'-1)}{R'}$, which, in the algebraic sense, is the sum of the reciprocals of the focal lengths of the separate lenses.

On writing $\mu+\delta\mu$, and $\mu'+\delta\mu'$ in place of μ and μ' in the last expression, we have for the reciprocal of the focal length of the compound lens for violet rays,

$$\frac{2(\mu+\delta\mu-1)}{R} - \frac{2(\mu'+\delta\mu'-1)}{R'}.$$

In an achromatic telescope the focal lengths of the compound lens for red and violet rays are to be equal to one another; and it is evident that this condition will be fulfilled when $\frac{\delta\mu}{R} - \frac{\delta\mu'}{R'} = 0$. From this equation we have $R : R' :: \delta\mu : \delta\mu'$: then, dividing the antecedents by $\mu-1$ and the consequents by $\mu'-1$, we have [Dispersion] the ratio of the focal lengths of the two lenses equal to that of the dispersive powers of the two kinds of glass; and hence, the focal length of the compound lens being assumed at pleasure, those of the separate lenses, consequently the radii of their surfaces, may be obtained.

In order to diminish the spherical aberration, the object-glasses of achromatic telescopes frequently consist of three lenses, of which the first and third are of the kind called double convex, and are formed of crown glass, while the second is double concave, and made of flint glass. In this case, since the index of refraction is the same for the third lens as for the first, if the radius of each surface of the third lens be R″, the reciprocal of the principal focal lengths of the separate lenses for red rays will be

$$\frac{2(\mu-1)}{R}, -\frac{2(\mu'-1)}{R'}, \text{ and } \frac{2(\mu-1)}{R''};$$

these being added together, their sum will be the reciprocal of the focal length of the compound lens for one kind of light. On substituting in the above terms, $\mu+\delta\mu$ for μ, and $\mu'+\delta\mu'$ for μ', in order to obtain the reciprocals of the focal length for violet rays, we shall have, when the chromatic aberration is corrected,

$$\frac{\delta\mu}{R} - \frac{\delta\mu'}{R'} + \frac{\delta\mu}{R''} = 0, \text{ or } R'\left(\frac{1}{R} + \frac{1}{R''}\right) = \frac{\delta\mu'}{\delta\mu}.$$

But $\frac{\delta\mu'}{\delta\mu}$ is known from tables of the refractive indices for different kinds of glass: therefore if any convenient relation between the radii of two of the lenses be assumed, the values of all the radii, and consequently the focal lengths of the several lenses, may be found.

The investigation of formulæ for the correction of the spherical aberration is a process of some labour, and is scarcely a fit subject except for a mathematical work: it is treated with great perspicuity in Robison's 'Mechanical Philosophy,' vol. iii., from which the subjoined theorem is borrowed, the notation only being changed for that which has been adopted above; and also in the articles Lens and Speculum. If a compound object-glass consists of one double convex lens of crown glass and a double concave lens of flint glass, and a ray of light be incident upon the anterior surface of the former in a direction parallel to the axis, at a distance from thence, which

is expressed by e; the distance from the lens, of the point at which the ray after refraction will meet the axis, is $f-f^2(q+q')$, where f is the focus for parallel rays infinitely near the axis, and may be found as above, and $e^2(q+q')$ is the aberration. Here, neglecting the thickness of the lenses and the interval between them,

$$q=\frac{\mu-1}{\mu}\left\{\frac{\mu^3}{n^3}-\frac{2\mu^2+\mu}{Rn^2}+\frac{\mu+2}{R^2n}\right\}\frac{e^2}{2}, \quad \text{and } n=\frac{RS}{R+S};$$

(R and S being the radii of the two surfaces of the convex lens,) and

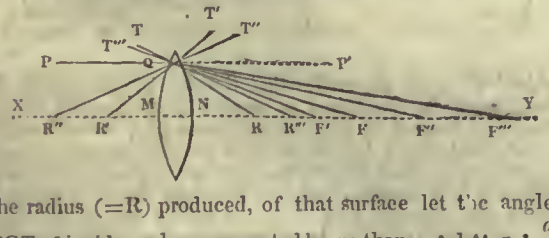
$$q'=\frac{\mu'-1}{\mu'}\left\{\frac{\mu'^3}{n'^3}-\frac{2\mu'^2+\mu'}{Rn'^2}+\frac{\mu'+2}{R'^2n'^2}+\frac{3\mu'^2+\mu'}{F.n'^2}-\frac{4(\mu'+1)}{F.R'n'}\right\}\frac{e^2}{2}:$$

where F is the principal focus of the convex lens, and $n'=-\frac{R'S'}{R'+S'}$; (R′ and S′ being the radii of the surfaces of the concave lens.)

It is evident that, in order to correct the spherical aberration, the values of the radii of the surfaces must be determined from the equation $q+q'=0$. This equation is however indeterminate, because it contains several unknown quantities; but it may be made subject to certain conditions by which there will remain only one: for example, the different radii of the lenses may be made to have any given relation to one another, so that the values of all, in terms of any one, may be substituted for them. In the values of q and q' the terms represented by n and n' are respectively equal to half the radii of equivalent isosceles lenses; and it has been shown, in the investigation concerning the chromatic aberration, that these are to one another as $\delta\mu$ to $\delta\mu'$; consequently $n'=n\frac{\delta\mu'}{\delta\mu}$, and therefore n' is known in terms of n. If again it be supposed that R′=S, or that the nearest surfaces of the convex and concave lenses have equal curvatures, the value of R may be found from the equation $q+q'=0$, in terms of n, by a quadratic equation.

Sir John Herschel, in a paper on the aberration of compound lenses and object-glasses (*Phil. Trans.*, 1821), has also investigated formulæ for the values of the chromatic and spherical aberrations; and M. Littrow, of Vienna, setting out with Euler's formula for spherical aberration (*Dioptrica*, tom. iii., 1769), and introducing in it the values of the focal lengths of two lenses so that the former aberration may be corrected, has obtained two equations from which the radii of the four surfaces may be determined by such conditions as may be thought convenient. (*Memoirs of the Astron. Soc.*, vol. iii., part 2.) In solving the problem relating to the determination of the four radii, Professor Littrow uses a method which possesses some facilities for computation, and on that account it has been adopted in the following process.

The radii of the surfaces of the first lens may be determined on the supposition that the whole refraction of light in passing through the lens is a minimum; that is, that the incident and emergent rays make equal angles with the surfaces, or with those radii. Thus let a ray PQ be incident on the first surface in a direction parallel to the axis XY of the lens, and infinitely near it; and RQT being



the radius (=R) produced, of that surface let the angle PQT of incidence be represented by a; then $\mu : 1 :: a : \frac{a}{\mu}$ (=RQF, the angle of refraction at that surface). But if R′QT′ be the radius (=S) produced, of the second surface; then, in the triangle R′QR, neglecting the thickness of the lens and substituting arcs for their sines, $S : R :: a : \frac{R}{S}a$; and $\frac{R}{S}a+a-\frac{a}{\mu}$ (=T′QF) is the angle of incidence on the second surface: and, by optics, 1 is to μ as this last angle is to $\frac{a\mu R}{S}+a(\mu-1)$, the angle of refraction (=T′QF′) at the second surface. But by hypothesis, this angle is to be equal to a; therefore $\frac{R}{S}=\frac{2-\mu}{\mu}$. Again, by optics, $\frac{RS}{R+S}\cdot\frac{1}{\mu-1}$ is equal to the focal length of the lens; and supposing this to be equal to unity, we obtain $\frac{R}{S}=\frac{R-\mu+1}{\mu-1}$: equating this last term with $\frac{2-\mu}{\mu}$ above, we get $R=\frac{2(\mu-1)}{\mu}$; whence $S=\frac{2(\mu-1)}{2-\mu}$. Therefore the two radii are found on the supposition that the focal distance of the lens is unity.

Now PQT being the angle of incidence as above, and QF the direction of the ray after one refraction, we have by optics, sin. RQF $=\frac{\text{sin. PQT}}{\mu}$; and by trigonometry, in the triangle RQF,

$$RF=R\frac{\text{sin. RQF}}{\text{sin. P′QF}}, \text{ and } MF=R\left(\frac{\text{sin. RQF}}{\text{sin. P′QF}}+1\right);$$

also, respresenting the thickness MN of the lens by t,

$$R'F=R\left(\frac{\text{sin. RQF}}{\text{sin. P′QF}}+1\right)+S-t.$$

Then, by trigonometry, in the triangle R′QF,

we get $\frac{SF+S-t}{S}$ sin. P′QF = sin. T′QF;

consequently by optics, $\frac{SF+S-t}{S}\mu$ sin. P′QF = sin. T′QF′,

or the sine of the angle of refraction at the second surface.

Now T′QF′ − T′QF + P′QF = QF′M, or the angle which the second refracted ray makes with the axis of the lens: but by trigonometry, in the triangle R′QF′, we have

$$R'F'=S\frac{\text{sin. T′QF}}{\text{sin. P′QF}}; \text{ whence } NF'=S\left(\frac{\text{sin. T′QF}}{\text{sin. P′QF}}-1\right).$$

Suppose next a double concave lens, the centres of whose surfaces are at R″ and R‴, and whose radii are R′ and S′, to be applied to the convex lens on the side N: then, neglecting the thickness of the concave lens and the distance between the two, and supposing QF″, QF‴ to be the directions of the ray of light after the third and fourth refractions respectively, we have in the triangle R″QF′, by trigonometry,

$$\frac{R'+S'F'}{R'}\text{ sin. P′QF′} = \text{sin. T″QF′},$$

or the sine of incidence on the first surface of the second lens; and by optics,

$$\frac{R'+S'F'}{R'\mu'}\text{ sin. P′QF′} = \text{sin. T″QF″}.$$

But P′QF′ − (T″QF′ − T″QF″) = P′QF″; and in the triangle R″QF″, by trigonometry, we have

$$R''F''=R'\frac{\text{sin. T″QF″}}{\text{sin. P′QF″}};$$

wherefore $NF''=R'\left(\frac{\text{sin. T″QF″}}{\text{sin. P′QF″}}-1\right)$; and considering NR‴ to be equal to S′, R‴F″ will be equal to NF″ − S′.

Again, in the triangle R‴QF″, we have by trigonometry,

$$\text{sin. R‴QF″}=\frac{NF''-S'}{S'}\text{ sin. QF″N}$$

for the sine of incidence on the fourth surface; therefore, by optics,

$$\frac{NF''-S'}{S'}\mu'\text{ sin. QF″N} = \text{sin. R‴QF‴},$$

the sine of refraction at the fourth surface: then

QF″N − (T‴QF″ − T‴QF‴) = P′QF‴, or = QF‴N;

and by trigonometry, in the triangle QF‴R‴, we have

$$R'''F''' = S' \frac{\text{sin. } R'''QF'''}{\text{sin. } QF'''N}, \text{ and } NF''' =$$

$$S' \left(\frac{\text{sin. } R'''QF'''}{\text{sin. } QF'''N} + 1 \right),$$

the focal distance of the compound lens.

These values being reduced to what they become when the incident ray PQ is infinitely near the axis of the lenses; that is, when the angles are substituted for their sines, there may be obtained

$$\frac{R}{MF} = \frac{\mu - 1}{\mu}, \quad \frac{S}{NF'} = \frac{\mu S}{MF - t} + \mu - 1,$$

$$\frac{R'}{NF''} = \frac{R'}{NF'\mu'} + \frac{\mu' - 1}{\mu'}, \text{ and } \frac{S'}{NF'''} = \frac{S'\mu'}{NF''} + \mu' - 1.$$

By means of these equations, eliminating the quantities MF, NF′, and NF″, and neglecting powers of t above the first, there may be obtained a value of $\frac{1}{NF'''}$: then differentiating this value with respect to μ, μ', and NF‴, and making the resulting value of the differential of NF‴ equal to zero (which is a condition necessary in order that the chromatic dispersion may be corrected for rays near the axis), there may be obtained a value of $\frac{1}{R'} + \frac{1}{S'}$. Again on substituting $\frac{2(\mu - 1)}{\mu}$ for R, and $\frac{2(\mu - 1)}{2 - \mu}$ for S, as above found, there will result

$$\frac{1}{NF'''} = 1 - \frac{\mu' - 1}{\mu - 1} \{1 + \tfrac{1}{2}(\mu + 1)t\} \frac{d\mu}{d\mu'} + \tfrac{1}{2}\mu' t, \text{ and}$$

$$\frac{1}{R'} + \frac{1}{S'} = -\frac{1}{\mu - 1} \{1 + \tfrac{1}{2}(\mu + 1)t\} \frac{d\mu}{d\mu'}.$$

Now the value of NF‴ may be directly computed from the formulæ first investigated; afterwards assuming different values of R′, and substituting them in the last equation, let the corresponding values of S′ be found. With these values of S′ find corresponding values of $S' \left(\frac{\text{sin. } R'''QF''}{\text{sin. } QF'''N} + 1 \right)$; that is, of NF‴, and proceeding according to the usual methods of trial and error, there will at length be found a value of NF‴ agreeing with that which was computed by the direct process: the four radii will then, consequently, be determined.

Investigations relating to the dispersion of light, and rules for computing the radii of curvature for achromatic object-glasses, will also be found in an essay by Mr. P. Barlow of Woolwich, printed in the 'Philosophical Transactions' for 1827.

Though on thus uniting the red and violet light by lenses of crown and flint glass the chromatic dispersion is in a great measure corrected, yet when the image is examined, it is found to be surrounded by a green-coloured fringe. The difficulty of procuring flint glass of sufficient purity is also a serious impediment to the perfection of achromatic lenses for telescopes; and though great rewards have been offered for glass which shall be free from defects, the exertions of artists have hitherto been almost without success. Occasionally however flint glass is obtained nearly homogeneous, and the opticians of Germany appear, in this respect, to have been more fortunate than those of England.

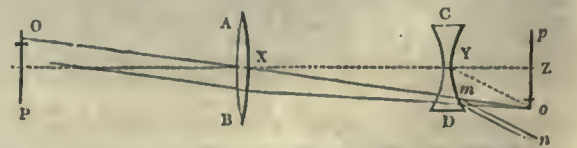
The late Dr. Ritchie obtained a disc of flint glass which was, by Mr. Dollond, formed into an object-glass nearly 7½ inches in diameter. It was applied to a telescope 12 feet long, and bore a magnifying power equal to 700 times: it is said to have had scarcely any spherical aberration, and to have been very free from colour. (*Mem. Astr. Soc.*, 1840.)

In the 'Transactions' of the Royal Society of Edinburgh, 1791, there is given an account of some experiments made by Dr. Blair, from which he was led to the discovery of a fluid medium, which, being applied between lenses of crown glass, renders the compound lens completely achromatic. By adding liquid muriatic acid to chloride of antimony, or sal ammoniac to chloride of mercury, he succeeded in obtaining a spectrum in which the coloured rays in each pencil followed the same law of dispersion as takes place in crown glass. Therefore, confining a small quantity of either of these liquids between the convex surfaces of two plano-convex lenses, or between those of a plano and a convex meniscus lens, of crown glass, Dr Blair obtained an object-glass in which the chromatic aberration was entirely destroyed; and he is said to have thus constructed one of 9 inches focal length, and as much as 3 inches in diameter or aperture. Object-glasses so made were for some years on sale in London; but either from the crystallization of the fluids, or the negligence of the artists in compounding them, the telescopes became imperfect, and gradually fell into disuse.

Dr. (Sir David) Brewster, in his 'Treatise on New Philosophical Instruments,' recommends the employment of sulphuric acid and oil of cassia for the composition of fluid lenses, by which the secondary spectrum may be destroyed; the acid being, of all known substances, that which exerts the greatest, and the oil that which exerts the least action on the green coloured rays. The correction of the chromatic dispersion by means of fluids has also recently been attempted by Mr. Barlow, who, in combination with a convex lens of crown glass, used a concave lens, consisting of sulphuret of carbon between two glasses (like that of a watch), of each of which the two faces were of equal curvature: this fluid has nearly the same refractive index as flint glass, and its dispersive power is more than double that of the latter material. The crown glass lens and the fluid lens, instead of being close together, were placed at a considerable distance from one another, by which disposition an increased magnifying power might have been obtained without increasing the length of the telescope. Probably from imperfections in the forms of the glasses, the images of objects were found to be not well defined; and the construction, in consequence, has not been adopted.

The image formed by the great speculum of a reflecting telescope is free from the inconveniences attending the chromatic aberration of light; for the angles of incidence being equal to that of reflection, in any pencil coming from a point in an object, all the rays will converge to one point at the place where the image is formed. If the surface of the speculum were that which is formed by the revolution of a parabola about its axis, then all the rays in any pencil proceeding from a very remote object, as one of the celestial bodies, and being incident on the speculum in a direction parallel to the axis, would, by the nature of the parabola, converge accurately in the focus of the curve; and on this account, an effort is always made to give to the reflecting surface of the speculum a paraboloidal figure. The advantage does not however hold good with the pencils which fall on the mirror in directions oblique to the axis; and therefore that figure is of less importance, when the telescope is to be used for viewing terrestrial objects, than when it is to be employed for astronomical purposes; for then, on account of the great distance of the objects, the several pencils of light fall on the mirror with a very small obliquity to its axis.

The telescope invented by Galileo consisted of one convex lens AB, and of a concave lens CD; the distance between them being equal to the difference between the focal lengths of the two lenses. In this instrument, if the



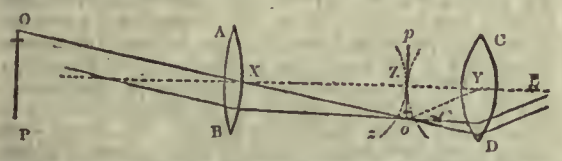
object OP were so remote that the rays in each pencil of light might be considered as parallel to one another, there would be formed at its principal focus an inverted image *op*, of that object by the union of the rays in each pencil in one point; then the concave lens being placed between AB and that image, in such a situation that its principal focus may coincide with the place of that image, the rays in each pencil will, by the refracting power of the lens, be made to emerge parallel to one another; and in this case, by the optical properties of the eye, distinct vision is obtained.

The line OXo is the axis of the pencil of light from O; and, as this passes through the centre X of the lens AB without refraction, the angle ZXo is equal to half the angle under which OP would be observed by an eye at X

when no telescope is interposed, while (*mn* parallel to Y*o* being the direction of a ray in that axis after refraction in CD) ZY*o* is half the angle under which OP is seen in the telescope: the ratio between these angles is therefore the measure of the magnifying power of the telescope; and since the angles are to one another as YZ is to XZ, nearly, it follows that $\frac{XZ}{YZ}$ nearly expresses the magnifying power.

This is the construction of what is called an *opera glass;* and the Galilean telescope is now used chiefly for viewing objects within a theatre, or an apartment, since if considerable magnifying power were given to it the extent of the field of view would be very small.

A simple telescope may also be constructed by means of two convex lenses, which are placed at a distance from one another equal to the sum of their focal lengths. For the image being formed at the focus Z, of the lens AB, which is nearest to the object, as in the Galilean telescope,

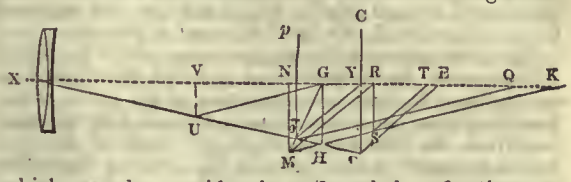


and being supposed to be a plane surface, the light also being supposed to be homogeneous; the rays of each pencil, after crossing at the focus and proceeding from thence in a divergent state, on being allowed to fall upon the surface of the second lens CD, may be refracted in the latter so as to pass out from thence in parallel directions; and consequently distinct vision of the object may be obtained by an eye situated so as to receive the pencils.

If X*o* be the direction of the axis of a pencil of light coming from O, one extremity of the object OP, which is supposed to be so remote that all the rays in each pencil may be considered as parallel to one another; then the angle ZX*o* is half the angle under which the object OP would be seen by an eye at X without a telescope, while the rays of that pencil entering the eye at E in the direction DE, which is parallel to oY, the angle ZY*o* is half the angle under which the same object is seen when viewed through the telescope. Now these angles are to one another nearly as ZY to ZX; therefore $\frac{ZX}{ZY}$ will express nearly the magnifying power of the instrument. As the pencils of light from O and P cross the axis of the eye at E before they are united on the retina, the image of the object OP is formed in the eye in a position contrary to that which is formed when the object is viewed without the telescope; therefore, on looking through the latter, the object OP appears to be inverted.

But the image formed at *op*, instead of being a plane, is nearly on a portion of a spherical surface whose centre is at X; and, on the other hand, in order that the rays in each pencil may after refraction in CD be parallel to one another, they ought to diverge from a point nearly in the surface of a sphere whose centre is at Y, the two spherical surfaces being in contact at Z: consequently when the distance between the lenses is such that the crossing of the rays in a pencil parallel to the axis takes place exactly at Z, the crossing *z* in one of the oblique pencils will be at a certain distance from the point *z'*, at which it ought to be to permit the rays in it to go out of CD parallel to one another; the rays of the pencils which proceed from the margin of the object will not then emerge parallel to one another, and consequently that margin will not be distinctly seen. Moreover from the unequal refrangibility of the different kinds of light, the rays in each pencil will be decomposed in passing through the lens CD, so that though the chromatic aberration were perfectly corrected in the image at *po*, it would exist in the image which is formed in the eye by the rays emerging from CD.

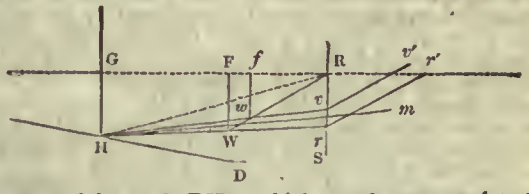
The spherical aberration can only be diminished by diminishing the inclination at which the rays in the marginal pencils fall upon the surface of the lens after having crossed at the focus of the object-glass; that is, by using a lens of less convexity or of greater focal length; adding a second eye-glass in order finally to render the rays in each pencil parallel to one another. Thus, if it be required to preserve the same magnifying power and field of view as might be obtained with any single eye-glass; let, as before, X be the place of the object-glass, *op* the image formed by it, and let CD be the place of the single eye-glass: then draw a line *o*Q so as to bisect the angle D*o*Y



which may be considered as the whole refraction produced by the lens CD: let G, on the right or left of *op*, be the assumed place of what is called the field-glass, and draw GH perpendicular to XY, the axis of the telescope, meeting XD in H; also through H draw MHK parallel to *o*Q, cutting G*o*, or G*o* produced, in M: again draw MN perpendicular to the axis of the telescope, and MR parallel to *o*Y; also draw RS perpendicular to the axis. Lastly, draw GU parallel to *o*Q to meet X*o* in U, and UV perpendicular to the axis. Then, from the principles of optics, if a lens be placed at G, having its focal length equal to GV, and another at R, whose focal length is RN; the ray X*o*H will by refraction in the first lens take the direction HS, and by refraction in the second lens it will take the direction ST parallel to *o*Y or DE: thus the present visual angle STR will be equal to DEY, which was obtained with the single eye-glass.

This is called the Huygenian eye-piece, and it is that which is generally used for astronomical telescopes: the object seen through it is inverted, as in the last-mentioned telescope.

If the places G and R of the two eye-glasses are given (GH being very near *op*; its focal length being also known), and it be required to find the focal length of RS so that the red and violet rays in each pencil may emerge from it parallel to one another, that length might be determined in the following manner. In a pencil of rays crossing each other at H, let H*m* be the direction of a mean ray, and H*r*, H*v* those of a red and a violet ray; these last will make with one another an angle equal to



about $\frac{1}{27}$ of the angle DH*m*, which may be supposed to be known. Now, by optical principles, if these rays are to emerge from RS in directions parallel to one another, the focal lengths of the lens for red and violet rays, viz. RF and R*f* must be to one another as 28 to 27, and the foci F and *f* must be in places determined by perpendiculars drawn to the axis from points W and *w*, in which the line RW supposed to be drawn parallel to *rr'* or *vv'*, meets H*r* and H*v*; that is, by finding the position of a line to be drawn from R to cut the given lines H*r*, H*v*, so that RW may be to R*w* as 28 to 27. For this purpose, having drawn the straight line HR, the angles RHW, RH*w* will be known; let them be represented by a and b; also let the angle HRW be represented by θ: then by trigonometry we shall have, after a few reductions, 27 cotan. a − 28 cotan. b = cotan. θ.

In order to afford a view of objects in the same position as they appear to have when seen by the naked eye, a telescope may be formed with three lenses besides the object-glass. In the construction of this instrument, if attention is paid only to the rays which suffer a mean refraction, the first eye-glass, or that which is nearest to the object-end of the telescope, may be placed between the image formed by the object lens and the eye, with the foci of the two lenses in coincidence; by this means the rays in each pencil will emerge from the first eye-glass in directions parallel to one another, those of the pencils which are oblique to the axis of the telescope crossing each other at some point in the latter axis. A second eye-glass is then placed at any convenient distance from the former, beyond the place where the oblique pencils cross each other; and by this lens a second image is

formed in a position contrary to that which is formed by the object lens. Lastly, the third lens being placed between this image and the eye at a distance from the former equal to its focal length, the rays in the several pencils will emerge parallel to one another, and an erect image of the object will thus be formed in the eye.

The ratio between the angles under which an object would be seen by the naked eye, and that by which it is seen in the telescope, is compounded of the ratios of the focal lengths of the several lenses: thus, if F be the focal length of the object-lens, f', f'', f''' those of the eye-lenses, reckoned in order towards the eye, the expression $\frac{F \cdot f''}{f' \cdot f'''}$ will denote the magnifying power.

But both the spherical aberration and the chromatic dispersion in such a telescope are very considerable; and before the invention of the achromatic object-glass, Mr. Dollond endeavoured to diminish the former by an eye-tube consisting of five lenses disposed so as to divide the bendings of the pencils nearly equally between them. Such telescopes are not now used; and Mr. Dollond succeeded at length in constructing telescopes with four eye-glasses, from which both distortion and colour are removed as much perhaps as a removal is possible.

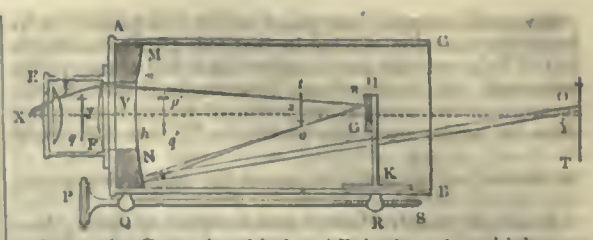
This is accomplished by placing the first eye-glass beyond the image formed by the object-glass, and at a distance from it less than the focal length of that eye-glass; by this disposition the rays of mean refrangibility in each pencil which diverges from the image are not, after refraction, parallel to one another, but go on with diminished divergency. A little way beyond the place where the axes of the oblique pencils cross the axis of the telescope there is placed the second eye-glass, which is of such focal length that the mean refrangible rays in each pencil, after passing through it, meet in a point, and thus a second image of the object is formed near the eye: the use of these two lenses, therefore, is to cause the second image to be formed by a gradual convergence of the rays in each pencil. But the several pencils of rays are intercepted by the third eye-glass (commonly called the field-glass), and the second image is thereby formed rather nearer to the first than it would be without such field-lens: from this image the rays in each pencil diverge, and by the refractive power of the fourth eye-glass they are made to enter the eye in parallel directions: thus distinct vision of the external object is obtained. The field-glass might have been placed between the eye and the second image, as in the Huygenian eye-piece before described; but the aberration arising from the spherical form of the glasses is a little less by the construction just mentioned.

Now, in each pencil, the red and violet rays which had been united at the image formed by the object-glass, and which there crossed each other, go on from thence diverging from each other till, on the opposite side of the axis of the telescope, they fall upon the surface of the second eye-glass: after passing through this lens, the violet ray, which is always more refracted than the red ray, gradually converges towards the latter, and at length meets it in some place short of that at which the rays of mean refraction unite to form the second image. The practice is to fix the third or field-glass exactly or nearly at the place where the red and violet rays so unite in all the pencils; for the different coloured rays crossing each other in that place, they are finally, by the refractive power of the fourth eye-glass, made to enter the eye in parallel directions, and thus afford a view of the object nearly or wholly free from colour.

In forming the eye-glasses of telescopes it may be observed that they should be such as will allow the incident and emergent pencils of rays to be nearly equally inclined to their surfaces: on this account the first and fourth eye-glasses are of the plano-convex form; the flat side of that which is nearest to the object-glass being towards the latter, and that of the other towards the eye.

It has been said above that, in reflecting telescopes, a speculum at one extremity of the tube serves the purpose of the object-glass in refracting telescopes by forming an image at its focus; and the manner in which, in the former instruments, the image is transmitted to the eye remains now to be explained.

The following diagram represents a longitudinal section through the axis XY of the instrument, which is supposed



to be of the Gregorian kind. AB is the tube which contains the specula, and is open at the end CB; and at the extremity nearest to the eye of the observer is a tube EF containing two lenses. MN is the anterior surface of the great speculum, which has a circular perforation, mh, at its centre: G is a small speculum, concave like the former, its surface being either spherical or parabolical. It is connected with the side of the tube AB by the arm HK, and is capable of being moved in the direction of the axis XY by means of the rod PS: the latter passes through a knob Q, which is fixed to the side of the tube, and works in the knob R, which passes through an oblong perforation in the side of the tube, and is attached to the part K of the arm HK. This movement is given to the small mirror in order that its focus may be made to coincide with the place of the image formed by the great speculum; that image being at different distances from the latter according to the distance of the object from the observer.

Let O be the upper part of an object, and let ON be the direction of the rays in a pencil of light diverging from O; the rays of this pencil will, after being reflected at N, converge to o, which will be the lower part of the image ot. From o the rays in the pencil diverge, and having fallen upon the small mirror at n, they are reflected from thence towards the eye-piece EF: having passed through the orifice mh, they fall on the lens at F, by which they are made to unite at p, where an image, pq, of the object is formed. From p the rays in the same pencil again diverge, and, falling on the lens at E, they are made to emerge in parallel directions, so that the eye is enabled to obtain distinct vision of the object in the same position as if the latter were viewed by the naked eye. The rays, after being reflected at n, might with a due concavity of the smaller mirror have united, as at p', in front of the great mirror, and the second image might have been formed at $p'q'$: in this case the rays in each pencil, after crossing one another, would have fallen in a divergent state on the lens at F, and then, by the refractive powers of both lenses, they would have entered the eye in parallel directions as before. The positions of the lenses at E and F, and the curvatures of their surfaces, are determined according to the method of Huygens; and the construction differs in no respect from that which has been described in speaking of the eye-pieces of dioptric telescopes.

The magnifying power of a reflecting telescope of this kind is expressed by the formula $\frac{Vz \cdot Gy}{Xy \cdot Gz}$; in which Vz is the focal length of the great speculum, Gy is the distance of the small speculum from the image pq, Xy is the focal length of the second eye-glass, and Gz is the focal length of the small speculum for parallel rays.

In the Cassegrainian telescope the small mirror G is made convex, and it is placed so as to intercept the rays from the great speculum MN before the image ot is formed; the rays of each pencil consequently fall in a convergent state on the small mirror, and, after reflection from thence, unite to form the image either at $p'q'$ or after refraction in the first eye-glass F. It is obvious that these telescopes, with equal magnifying power, will be shorter than the Gregorian telescopes by more than twice the focal length of the small speculum; and it may added that, in some degree, the spherical aberration is corrected by the contrary curvatures of the two mirrors.

The Newtonian reflecting telescopes have one concave speculum at the bottom of the tube; and, in each pencil of light, the rays reflected from it fall in a convergent state upon a small plane mirror placed so as to make an angle of 45° with the axis XY of the telescope: after the second reflection the rays unite and form an image which is viewed through a Huygenian eye-piece fixed in the side of the tube AB, opposite the plane mirror; that is near the open end of the tube.

The great telescope constructed by Herschel differs from the Newtonian telescope only in having no small mirror. The surface of the great speculum, which is 4 feet in diameter, has a small obliquity to the axis XY, so that the image formed by reflection from it falls near the lower side of the tube at its open end: at this place there is a sliding apparatus which carries a tube containing the eye-glasses. The observer in viewing, is situated at the open end of the tube, with his back to the object, and he looks directly towards the centre of the speculum, the magnitude of which is such that the rays intercepted by his head, in coming from the object, do not in any sensible degree diminish the brightness of the image.

Formerly the great speculum of a reflecting telescope was pressed into its cell by means of springs attached to the interior side of the brass plate at A; but the vibrations of the springs were found to cause tremulous motions in the image at the focus of the mirror; and this effect was so great as to render reflecting telescopes inferior to those of the dioptric kind. The Reverend Mr. Edwards, who detected the cause of the tremors, at once removed it by taking away the springs (*Naut. Alm.*, 1787); and the same gentleman further improved the distinctness of the image by enlarging the aperture to which the eye is applied. It has been observed also that when the great speculum is nearly in a vertical position, and consequently rests on its lower extremity, its weight bends it, and thus causes a change in the figure of its polished surface: on this account it is recommended that the speculum should be made to rest on two small wedges, placed one on each side, at about 45 degrees from the lowest point.

Besides the power of magnifying objects, that of affording distinct vision with given quantities of light is often an essential requisite in a telescope, particularly to naval men, who have occasion during the obscurity of the night to keep in view a ship of which they may be in chase. This subject was investigated by the late Sir William Herschel, and an account of his researches on what he calls the 'space-penetrating power of telescopes' was printed in the *Philosophical Transactions for* 1800.

Herschel states that he was aware of this property of telescopes as early as the year 1777, when he had constructed a Newtonian telescope with a speculum whose focal length was 20 feet: for, on directing the instrument to a church-steeple at a considerable distance, he could distinguish the hour by the clock, though with the naked eye he could not see the steeple itself. In order to obtain a formula for the space-penetrating power, he observes that the quantity of light received by the natural eye varies directly with the aperture of the *pupil*, or with the square of its radius, and inversely with the square of the distance of the object: also that the quantity of light transmitted by a telescope, supposing none to be lost in the reflections from the mirrors, or in refraction through the lenses, will vary directly with the square of the radius of the aperture and inversely with the square of the distance of the object. But, from experiments on the measure of light, it appears that the whole quantity incident upon a plate of glass is to the quantity transmitted through it as 1 is to ·9381, or to the quantity lost as 1 is to ·0619; and from this, the whole quantity of incident light being unity, an estimate may be made of the quantity of light transmitted through all the lenses of a telescope: with respect to the quantity lost in reflection from mirrors Sir W. Herschel found that out of 100,000 incident rays, only 45,242 reached the eye after two reflections.

Let the quantity of incident light be to that which arrives at the eye as 1 to m; then r being the radius of the pupil, and R that of the aperture of a telescope, $\frac{R^2 m}{r^2}$ will express the ratio between the quantity of light transmitted to the naked eye, and through a dioptric telescope: therefore the space-penetrating power varying with the square root of the quantity of light, $\frac{R}{r}\sqrt{m}$ expresses the penetrating power. With respect to reflecting telescopes, if R′ be the radius of the small speculum, the penetrating power will be expressed by $\frac{1}{r}\sqrt{\{m(R^2-R'^2)\}}$. It is necessary to observe that, in these expressions, it is supposed that the pencil of light transmitted by the telescope is not greater than the pupil of the eye.

TELESCOPE, HISTORY OF THE. It has been the fate of almost every instrument by which science has been extended, or the well-being of man promoted, that the precise epoch of its invention, and even the name of the individual to whom the world is indebted for it, are alike unknown. This is particularly the case with the telescope, of which the earliest notices are that it existed in England and in Holland near the end of the sixteenth or in the beginning of the seventeenth century.

There is in Strabo a passage (iii., p. 180, Falconer's ed.; p. 138, Casaub.) in which, speaking of the enlargement of the sun's disk at his rising and setting in the sea, it is stated that the rays (of light) in passing through the vapours which rise from the water, as through tubes, are dilated, and thus cause the apparent to be greater than the real magnitude (of the object); and from this it has been inferred (Dutens, *Recherches*, &c.), though the inference is probably without foundation, that there then existed tubes furnished with lenses for magnifying objects by refracting the light. It would be needless to make any observations on an inference founded upon an hypothesis so obscurely expressed: the words in Strabo probably signify only that the rays of light might become divergent in passing along the intervals between the particles of vapour.

Omitting then all notice of this, and of the ill understood passages in Aristophanes ('Clouds') and Pliny (lib. xxxvi., c. 67) concerning transparent spheres, or lenses for concentrating the rays of light, it must be acknowledged that before the end of the thirteenth century lenses of glass were in constant use for the purpose of assisting the eye in obtaining distinctness of vision. Vitello, a native of Poland, in that century, gave some obscure indications of the apparent magnitudes of objects when viewed through a segment of a sphere of glass; and Roger Bacon, in his 'Opus Majus,' both mentions the like fact, and expresses himself in such a manner as to indicate that in his time (he died in 1292) spectacles were already in use. He may not have actually made combinations of lenses in one instrument, but there is no doubt of his being aware of the fact that lenses might be arranged so that objects seen through them would appear to be magnified. [Bacon, Roger; Spectacles.]

The idea being known to the learned, it is scarcely possible to doubt that the combination of two lenses, or of a concave or convex mirror and a lens, must have been often made during the three centuries which elapsed between the time of Bacon and that which is generally considered as the epoch of the invention of telescopes. Dr. Dee, in his preface to Euclid's 'Elements' (1570), having mentioned that some skill is required to ascertain the numerical strength of an enemy's force when at a distance, observes that the 'captain, or whosoever is careful to come near the truth herein, besides the judgment of his eye, the help of his geometrical instrument, ring, or staffe astronomical (probably for determining the measure of distances), may wonderfully help himself by perspective glasses:' these last can only signify some kind of telescope, which therefore must have been then in general use. And in the 'Pantometria' of Digges (1571) it is stated that 'by concave and convex mirrors of circular (spherical) and parabolic forms, or by frames of them placed at due angles, and using the aid of transparent glasses which may break, or unite, the images produced by the reflections of the mirrors, there may be represented a whole region: also any part of it may be augmented, so that a small object may be discerned as plainly as if it were close to the observer, though it may be as far distant as the eye can descrie.' In the preface to the second edition (1591) the editor, who was the author's son, affirms that 'by porportional mirrors placed at convenient angles, his father could discover things far off, that he could know a man at the distance of three miles, and could read the superscriptions on coins deposited in the open fields.' There is probably some exaggeration in this account, but it is sufficiently manifest from it that reflecting telescopes, or optical instruments containing combinations of mirrors and lenses, were known in England before the end of the sixteenth century. The claim of Baptista Porta (between 1545 and 1615) to the invention of the telescope appears to have no other foundation than the circumstance that

ne perceived a small object to be magnified when viewed through a convex lens.

It is highly probable that the telescope had been invented long before the value of such an instrument was duly appreciated; and it may have been owing to the very gradual discovery of its importance that the name of the inventor sunk into oblivion: about the middle of the seventeenth century, however, an effort was made to discover the traces of the invention, and Peter Borellus, in his work entitled 'De vero Telescopii Inventore,' which was published in 1655 at the Hague, has given testimonials in favour of two persons; the first of these is Zachariah Jans, or Jansen, and the other, Hans Lapprey, or Lippersheim, both of whom are said to have been opticians, or spectacle-makers, residing at Middleburgh: in a letter written by a son of Jans, it is stated that the epoch of the discovery is the year 1590; but by another account, the year 1610. The same author has also given a letter from M. William Boreel (envoy from the States of Holland to the British Court) which seems to throw some light on the facts. The writer of the letter asserts that he was acquainted with the younger Zachariah Jans, when both of them were children, and had often heard that the elder was the inventor of the *microscope*: he adds that, about the year 1610, the two opticians Jans and Lapprey first constructed telescopes, and that they presented one to Prince Maurice of Nassau, who desired that the invention might be kept secret as (the United Provinces being then at war with France) he expected to obtain in the field, by means of the instrument, some advantages over the enemy. The writer further states that the invention became known, and that soon afterwards Adrian Metius and Cornelius Drebbel went to Middleburgh and purchased telescopes at the house of Jans. This account differs from that which is given by Descartes ('Dioptrics,' cap. 1), who, writing in Holland, states that about thirty years previously, Metius (who was, he observes, a native of Alckmaer), having always taken pleasure in forming burning-mirrors and lenses of glass and of ice, by chance placed at the extremities of a tube two lenses, one thicker in the middle, and the other thinner, than about the edge (convex and concave); and thus, he adds, was formed the instrument which is called a telescope. The 'Dioptrics' was published at Leyden in 1637, and therefore the time of the supposed invention by Metius is nearly coincident with that at which, according to Borellus, it was made by Jans. From the papers of Harriot, it appears that this mathematician observed spots on the sun, in 1610, with telescopes magnifying from 10 to 30 times; but it is uncertain whether he got them from Holland, or whether they were made in this country; and the only conclusions at which it is possible now to arrive, are, that telescopes were known in England and Holland about the end of the sixteenth century, and that in both countries they were then in a form which rendered them practically useful.

The two Jansens, father and son, appear to have used their telescopes in observing the heavens; and the latter is said to have remarked four small stars near Jupiter: it has been concluded from thence, that he was the first discoverer of the satellites of that planet; but though this may be, he probably did not continue his observations long enough to enable him to determine their distances from it, or the times of their revolutions.

The use of the telescope, and, probably, even the knowledge of the fact that it had been invented, must have been for many years confined to the north of Europe; for it appears that it was not till the year 1609 that Galileo, who then happened to be at Venice, heard from a German a rumour of the discovery which was said to have been made in Holland. The Italian philosopher states, in the 'Sidereus Nuncius,' that he had then no knowledge of the nature of the instrument, and that he requested a friend at Paris to send him some information concerning it. On being informed, merely, that it was a tube containing glass lenses, his acquaintance with the nature of the refraction of light enabled him, it is said, to discover that one of the lenses must have been convex and the other concave, and also to determine the distance at which they should be placed from one another in order that the objects seen through them might appear magnified and distinct. Without however supposing that Galileo was here guided by theoretical considerations merely, it is easy to conceive that, as lenses of different forms were then in use for spectacles, he might have obtained from an optician some which were of different degrees of convexity and concavity; and after a few trials he must have found such as would constitute an instrument possessing magnifying power.

The telescopes which he constructed consisted of one convex object-glass and one concave eye-glass, which were placed at the extremities of a leaden tube; and the first of them magnified the heights and breadths of objects three times only. Soon afterwards he made one which magnified eight times; and subsequently he succeeded in forming a telescope with a magnifying power which caused objects to appear about thirty times as great as they are to the unassisted eye.

The knowledge which man had acquired of the visible heavens received many important accessions from the discoveries which Galileo was enabled to make by means of the telescope. Except the sun and moon, not one of the celestial bodies had hitherto been observed to have any visible form or magnitude, and it was to the eye of reason alone that those appeared to be anything but plane surfaces: the fixed stars and the planets were alike known only as luminous and ill-defined points; but when seen through a telescope, the planets were found to have certain magnitudes, and some of them to undergo variations of form; while the fixed stars appeared unchanged, or only divested of the radiance with which they seem to be surrounded when seen by the naked eye; and hence it became obvious that the former must constitute a distinct group of bodies infinitely nearer the earth than the others. The sun, from the spots observed on his surface, was found to revolve on its axis, and consequently was ascertained to be globular; and the light and dark spaces on the moon were distinctly perceived to be mountains and valleys, nearly resembling those features on the surface of the earth. Galileo relates, in the work above mentioned, that in the year 1610 he discovered the four satellites of Jupiter, and observed that they revolved about that planet as our moon revolves about the earth. Nearly at the same time he observed that Saturn presented a remarkable appearance: at first he thought it was accompanied by two smaller planets; but on using a telescope of superior magnifying power, these were found to be portions of a vast annulus which surrounds Saturn without touching his surface; and soon afterwards he ascertained the fact that Venus exhibited phases similar to those of the moon.

The species of telescope which was used by Galileo continued for several years unchanged; yet it is extremely defective, on account of the small extent of the field of view which it affords when its magnifying power is considerable; and the Batavian or Galilean telescope, as it was called, is now chiefly used to distinguish objects in a theatre. It is due to the memory of Kepler to state that he pointed out (in his 'Dioptrics') the possibility of forming telescopes with two lenses, both of which are convex; but he did not reduce his ideas to practice by the construction of such an instrument, and the honour of having been the first to do so is to be attributed to the Jesuit Scheiner, who, in his 'Rosa Ursina' (1650), gives a description of telescopes with one convex eye-glass. He observes that they cause the images of objects to appear in inverted positions; and adds, that thirteen years previously he had used such a telescope in presence of the Archduke Maximilian.

Telescopes with a single convex eye-glass have been since designated astronomical, from the circumstance that they were long employed for celestial observations; the greater extent of their field of view having caused them, notwithstanding the inversion of the image, to supersede for that purpose the telescopes of Galileo. It ought to be remarked however that telescopes with two eye-glasses, by which the object might be seen in a direct position, as it appears to the naked eye, were described by Kepler, and constructed by Scheiner; but as they caused the object to appear much distorted and coloured about the margin of the field, they were not esteemed. Père de Rheita, about the same time, constructed for telescopes eye-tubes containing three lenses, which, he observes, afford a better image than those with two: the same person was the inventor of what is called a binocular telescope, that is, an instrument which consists of two telescopes having equal magnifying powers, and placed near

each other in such positions that an object might be observed with both eyes at the same time. Attempts have been since made to revive this invention; but the advantages, if any there be, are more than compensated by the trouble of directing the two tubes to the object.

The magnifying power of a dioptrical telescope increasing with the ratio which the focal length of the object-glass bears to that of the eye-glass, and since, by increasing the focal length of the former without increasing its diameter, the coloured border round the image is diminished so that vision is rendered more distinct, the opticians of the seventeenth century were induced to form, for object-glasses, lenses which were segments of very great spheres, that is, lenses of great focal lengths. Campani at Bologna, by order of Louis XIV., made telescopes having object-glasses whose focal lengths were as great as 136 feet, and with such, Cassini, in 1671, discovered the satellites of Saturn. [Campani.] M. Auzout is said to have made a lens of 600 feet focal length, but it does not appear that he was able to use it as a telescope.

Huygens, who was an ingenious mechanic as well as a good philosopher, contrived to use an object-glass of long focus for astronomical purposes without placing the system of lenses in a tube. On the top of a long pole which was planted vertically in the ground, he mounted the object-glass, having fixed it in a frame with joints so that its axis could be moved in any direction by means of a string which was held in the hand of the observer; and the axis being in a line passing through the celestial body, a short tube containing the eye-glasses was fixed to a stand near the ground with its axis in the same direction. An instrument of this kind having an object-glass of 123 feet focal length, was made by Huygens and presented to the Royal Society; and with it Dr. Bradley made some of his astronomical observations. It is described by Huygens in his 'Astroscopia Compendiaria,' which was printed at the Hague in 1684. But the chief merit of Huygens as an improver of astronomical telescopes consists in his construction of an eye-piece with two lenses so combined as both to enlarge the field of view and diminish the aberrations produced by their spherical forms.

There is some probability that the elder Digges had contrived an instrument which constituted a species of catoptric, or reflecting, telescope; but, on account of the obscure manner in which the instrument is described, it will be scarcely necessary to notice further his claim to the honour of the invention. It appears that Père Mersenne, in his correspondence with Descartes, and in his 'Catoptrics' (1651), suggested the idea of a concave spherical mirror to be used, like the principal lens of a dioptric telescope, for forming in its focus an image of an object; and that this image being viewed through a convex eye-glass of proper curvature, the original object would appear to be magnified. Descartes, in his reply to Mersenne, which is said to have been written in 1639, makes several objections to the scheme, and no effort was then made to put it in practice. But the great length of the dioptric telescopes which were then in use rendering the management of them very inconvenient, ingenious men were induced to attempt a construction in which with equal magnifying power much smaller dimensions might be employed. Mr. James Gregory of Edinburgh, in his 'Optica Promota' (1663) published a suggestion for forming a telescope by means of the image at the focus of a concave speculum. The mirror was to be of polished metal with a paraboloidal surface, which by the properties of that curve would cause all rays incident upon it in directions parallel to the axis to converge accurately at one point. It is uncertain whether Gregory had any knowledge of Mersenne's treatise, or whether the idea originated with himself; but this is of little consequence, for not being able to find an artist who could execute such a speculum, though he came to London for the purpose, the suggestion was abandoned, and men of science continued to direct their inquiries to the means of improving dioptric telescopes.

When, however, Newton had discovered the unequal refrangibility of light, and had ascertained that the aberration produced by this cause about the focus of a lens was many hundred times greater than that which was caused by the spherical form of the glass, he gave up the hope of being able to construct refracting telescopes which should be free from this defect, and applied himself to the formation of specula for those of the catoptric kind: the image formed by reflection from a mirror being free from what is called the chromatic aberration, and consequently incomparably more distinct than one which is formed by the refraction of light in a lens of any transparent medium.

In the beginning of 1669, Newton having obtained a composition of metals which appeared likely to serve for a mirror, began with his own hands, to grind its surface to a spherical form; and early in the year 1672 he completed two telescopes: of the construction and performance of these instruments he sent to the Royal Society an account which was read in the January of that year. The radius of the concave metal in one of them was 13 inches, and the telescope magnified about 38 times. The rays, before forming an image in the focus of the speculum, were intercepted by a glass prism, or a plane mirror, and the image formed after this second reflection was viewed by a convex eye-glass which was fixed for the purpose in the side of the tube. In the telescope proposed by Gregory, the rays in each pencil of light, after crossing at the focus of the great speculum, were to fall upon the surface of a small concave mirror; and by this being again reflected, they were to form a second image near the anterior surface of the first speculum: through a perforation in the latter the image was to be viewed; a convex lens being interposed between the image and the eye of the observer. This has been always called the Gregorian telescope; and in 1672, the year in which Newton completed his reflecting telescopes, M. Cassegrain, in France, proposed one which differed from that of Gregory only in the rays reflected from the great speculum being intercepted by a small convex mirror: from this the rays of each pencil were again reflected, and they were made to form an image near the anterior surface of the great speculum: this image was to be viewed through a convex lens behind an aperture in the latter speculum, as in the telescope of Gregory. It does not appear that M. Cassegrain constructed such a telescope, but it may be observed that the image formed after reflection from the convex speculum would be more free from the aberration caused by the surfaces of the mirrors, and would also be rather greater, than that which is obtained from the concave speculum of Gregory or the plane one which was used by Newton.

The first reflecting telescope, in which the great speculum was perforated so that objects could be viewed by looking directly at them, was executed by Dr. Hooke, and produced before the Royal Society in February, 1674. But the difficulty of obtaining metal proper for the purpose, and of giving it a perfectly spherical form, for a long time prevented reflecting telescopes from attaining the desired degree of perfection. In 1718 Mr. Hadley succeeded in executing two telescopes, each about five feet long, which were considered good; and he gave, in the 'Philosophical Transactions' (1723), a description of the methods employed in their construction. By his advice Dr. Bradley, who was then professor of astronomy at Oxford, in conjunction with Mr. Molyneux at Kew, applied themselves to the construction of these instruments: having executed one which was satisfactory, they in 1738 instructed Scarlet and Hearne, two London opticians, in the processes which they used, and these artists presently succeeded in making good reflecting telescopes for general sale. Mr. James Short, of Edinburgh, also soon afterwards distinguished himself by his skill in forming such telescopes: he attempted at first to make the principal speculum of glass, but finding that this material had not sufficient steadiness to preserve the form of its surface, he devoted himself to the improvement of metallic specula, and succeeded in giving them, it is supposed, a correct parabolic figure, by which means his telescopes admitted of larger apertures than any that had before been made.

The processes adopted by Mr. Mudge in grinding and polishing the mirrors for reflecting telescopes, and in giving them the parabolic figure, may be seen in the 'Philosophical Transactions' for 1777. See also Speculum Metal.

But the reflecting telescope was destined to receive the highest power of which perhaps it is susceptible from the hands of Dr. (afterwards Sir William) Herschel: this distinguished astronomer, while residing at Bath, employed his leisure hours in grinding and polishing specula, with

which he formed telescopes, both of the Newtonian and Gregorian kinds; and about the end of 1780, that is, subsequently to the discovery of the planet which is called by his name, being aided by the liberality of the king (George III.), he began the formation of a speculum four feet in diameter and forty feet in focal length: the telescope to which it appertains is of the Newtonian kind, the observer being placed in a seat near the open end of the tube, and viewing the image through a system of eye-glasses. With this telescope, which was completed in 1789, objects are magnified about 6500 times; and on the night after it was finished, Dr. Herschel discovered the sixth satellite of Saturn. An attempt is even now being made to form a reflecting telescope possessing a higher degree of perfection than that of Herschel; but though the expectation should be fulfilled, telescopes of great magnitude must always be inconvenient in the management; and, from the expense of their construction, they will ever be confined to a few persons. It is right to observe moreover that the greatest discoveries of which astronomy can boast have been made with telescopes whose magnifying power did not exceed 700 times.

While the improvement of reflecting telescopes was in progress, the efforts to combine glass lenses in order to diminish the coloured fringes by which the images in dioptrical telescopes are surrounded were not entirely neglected; and as early as 1729, a private gentleman, Mr. Chester More Hall, of Essex, influenced, it appears, by an opinion that the humours of the eye are combined so as to correct the dispersions which each alone would produce in the different kinds of light, contrived to combine two lenses of different kinds of glass in such a way as to form an image which was free from colours: it is added that telescopes with such object-glasses were in the possession of several individuals many years afterwards. (*Gent. Mag.*, October, 1790; *Phil. Mag.*, November, 1798.)

In 1747 Euler, guided also by the constitution of the eye, conceived the possibility of forming a lens compounded of two hollow spherical segments of glass, inclosing water between their concave sides, which should be free from the chromatical and spherical aberrations; and in investigating the curvatures he assumed that the logarithms of the terms expressing the ratio of the refraction of a mean ray in passing from air into glass, and from air into water, were proportional to the logarithms of the terms expressing the ratio of the refractions of red rays in the same media. He was not able to obtain from any artist a lens of this nature, in which the proposed end was accomplished, and Mr. Dollond [DOLLOND], in a short paper which is printed in the 'Philosophical Transactions' (1752), contested the justness of Euler's principle on the ground that it was contrary to one which he conceived to be founded on the experiments of Newton.

But M. Klingenstierna, a Swedish mathematician, having soon afterwards, in a Mémoire which was sent to the Académie des Sciences, pointed out that the principle which had been adopted by Dollond was not conformable to the acknowledged laws of refraction, the latter determined immediately on having recourse to experiment. Either guided by the object-glasses constructed under the direction of Mr. Hall, or from a series of experiments made by himself on the refraction of light in wedges of crown and flint glass, he discovered that by employing a convex lens of the former, in combination with a concave lens of the latter kind, the rays of the different colours in each pencil of light, after refraction through both, might be made to unite at the focus, and thus produce an image of the object nearly free from colour. For this important discovery Mr. Dollond received from the Royal Society the Copleian medal. In 1765 his son, Mr. Peter Dollond, diminished the aberration of light on account of the spherical forms of the lenses by combining together two convex lenses of crown glass with a concave lens of flint glass between them: this construction is particularly advantageous, by the increased aperture which it allows when the focal length of the compound lens is short.

For several years after the telescopes thus improved by Dollond had been in general use, Euler continued to believe that all kinds of glass differed but little from each other with respect to their dispersive power, and he ascribed the success of the English artist merely to a fortunate determination of the curvature of his lenses; but having, in the year 1764, received information that, by the addition of lead, glass had been obtained whose dispersive power was four times as great as that of the common kind, he immediately renounced his former opinion; and from that time the merit of the achromatic object-glasses, as they were called, has been firmly established. The most eminent mathematicians, both on the Continent and in this country, have subsequently investigated, on scientific principles, the curvatures which should be given to the surfaces of lenses, so that, the focal length of the compound lens being assumed, the chromatical and spherical aberrations may be corrected.

The arrangement of lenses for the eye-pieces of telescopes is of no less importance than the formation of the object-glass; and Huygens proposed (*Dioptrics*, prop. 51), in order to diminish the refraction of light at the surfaces, to substitute for the single eye-glass of the common astronomical telescope two convex lenses, of such curvatures that the whole refraction, or the angle between the incident and emergent ray in the former construction, should be divided between the two lenses.

One mode of effecting this purpose is to place the first eye-glass, or that which is nearest to the object, so as to intercept the pencils coming from the object-glass before the rays are united, and thus the image is formed after the refraction of the light in this lens: the second eye-glass is then placed so that the rays falling on it, after having crossed at the place of the image, are made to enter the eye parallel to one another. A micrometer cannot be applied to such an eye-piece, since any change in the place of the lens which is nearest to the eye would derange its adjustment: these eye-pieces can however be rendered achromatic, and they have the greatest possible field of view; they have therefore been constructed for the purpose of merely viewing the celestial bodies by Dollond, Ramsden, and Frauenhofer. Mr. Ramsden was the first who constructed eye-pieces with two lenses which were capable of being used with a micrometer: this he accomplished by placing the tube containing those lenses so that the rays in the pencils, after crossing at the focus of the object-glass, fell in a diverging state upon the first eye-glass, and, after refraction in both, entered the eye in parallel directions.

With both these kinds of eye-pieces the object appears to be inverted; but eye-pieces with three lenses, by which the object is made to appear in the erect position, had been proposed by Rheita: these being found defective, Mr. Dollond endeavoured to improve upon the construction by dividing the refraction at the first and third eye-glasses between two lenses, according to the method recommended by Huygens, and thus he formed eye-tubes with five lenses. But some light is always lost by reflection when it falls upon glass; and, in order to diminish this evil, Dollond subsequently, retaining the Huygenian construction in the two lenses nearest to the eye, used but one lens to perform the office of the second and third (in the eye-piece with five glasses), in rendering the rays of each pencil convergent after the first had diminished the divergency caused by the crossing at the focus of the object-glass: he thus succeeded in producing an eye-piece of four lenses which was nearly *aplanatic*, or free both from the chromatical and spherical aberrations; and such are the telescopes now in common use for viewing terrestrial objects.

The chief improvements, if they may be so called, which have since been made in dioptric telescopes, consist in the means which have been adopted to remove those aberrations more completely; and the natures of the different media which have been used for this purpose by Dr. Blair, Sir David Brewster, and Mr. Barlow, have been mentioned in the article TELESCOPE.

Attempts have been made by M. Chevalier to diminish the aberrations by means of two achromatic object-glasses placed at a certain distance from each other in the tube; and by Mr. Rogers of Leith, by a single convex lens of plate glass, in combination with a double achromatic lens, the convex lens being of plate-glass, and the concave lens of flint-glass. This last gentleman proposes to unite the red and violet rays at the image of the object by a proper distance between the single and the double lens, and to correct the spherical aberration either by giving proper curvatures to the surfaces of the compound lens, or by placing the two lenses at a small distance from each other. (*Memoirs of the Astron. Soc.*, vol. iii., part 2.) Dr.

Brewster has suggested (*Treatise on New Phil. Inst.*, p. 400) that it may be possible to remove, or at least very much diminish, the uncorrected colour in the image by the use of two lenses of the same kind of glass with the same or different dispersive powers. He proposes that the exterior lens should have the meniscus form, the convex side being outwards; in order, from the obliquity of the incident rays to the surface, that the dispersion produced by that lens may increase in a higher ratio than its refraction, so that the dispersion produced by the other lens may be corrected; while in each pencil the rays, after retraction through both, may be convergent.

It would be improper to omit here to mention that M. Amici at Modena, some years since, invented a species of achromatic telescope by a combination of four prisms, all of the same kind of glass: the refracting edges of one pair of the prisms were parallel to one another, and those of the other pair were also parallel to one another, but perpendicular to the edges of the first pair; and each pair formed an achromatic combination. By the refraction in the first pair the breadth of the object is magnified, and by that in the second pair the length is magnified in the same ratio: thus the result is an image undistorted and magnified. Sir John Herschel states that, in 1826, he saw in the hands of its inventor one of these telescopes, which magnified about four times.

TELESCO'PIUM (the Telescope), a constellation of Lacaille, in the southern hemisphere, surrounded by Ara, Pavo, Sagittarius, and Ophiuchus. Its principal stars are as follows:—

TELESCO'PIUM, De Montfort's name for the *Cerithium Telescopium* of authors. [ENTOMOSTOMATA, vol. ix., p. 451.]

TELFORD, THOMAS. In the life of this eminent man, as has been observed in a brief notice of the fathers of that science of which he was so distinguished an ornament, in the preface to the 'Transactions' of the Institution of Civil Engineers, 'another striking instance is added to those on record of men who have, by the force of natural talent, unaided save by uprightness and persevering industry, raised themselves from the low estate in which they were born, to take their stand among the master-spirits of their age.' Telford's father was a shepherd in the pastoral district of Eskdale in Dumfriesshire, where, in the parish of Westerkirk, his only son was born, on the 9th of August, 1757. His father dying while he was yet an infant, the care of Telford's early years devolved upon his mother, Janet Jackson, for whom he cherished an affectionate regard until her death in 1794; he having been in the habit, according to Mr. Rickman, of writing letters to her in *printed* characters, that she might be able to read them without assistance. He received the rudiments of education in the parish school of Westerkirk; and, while engaged during the summer season as a shepherd boy in assisting his uncle, he made diligent use of his leisure in studying the books furnished by his village friends. At the age of fourteen he was apprenticed to a stone-mason in the neighbouring town of Langholm; and for several years he was employed, chiefly in his native district, in the various operations usually performed by a country mason in a district where there is little occasion for the higher departments of his art. The construction of plain bridges, of farm buildings, and of simple village churches and manses, afforded however good opportunities for obtaining practical knowledge. Telford himself has expressed his sense of the value of this humble training, observing, that although convenience and usefulness only are studied in such erections, yet peculiar advantages are offered to the young practitioner; 'for,' to adopt his own words, 'as there is not sufficient employment to produce a division of labour in building, he is under the necessity of making himself acquainted with every detail in procuring, preparing, and employing every kind of material, whether it be the produce of the forest, the quarry, or the forge; and this necessity, although unfavourable to the dexterity of the individual workman who earns his livelihood by expertness in one operation, is of singular advantage to the future architect or engineer, whose professional excellence must rest on the adaptation of materials and a confirmed habit of discrimination and judicious superintendence.' Chambers states that during this period of his life Telford was remarkable for the neatness with which he cut letters upon gravestones. In 1780, being then about twenty-three, and considering himself master of his art, he visited Edinburgh, apparently with a view to obtaining employment. The splendid improvements then in progress in that city enlarged his field of observation, and enabled him to contemplate architecture as applied to the object of magnificence as well as utility; and he seems at this time to have devoted much attention both to architecture and drawing. After remaining there about two years, he removed to London, where he obtained employment upon the quadrangle of Somerset House, then erecting by Sir William Chambers, an engagement in which, according to his own account, he obtained much practical information. About 1784 he was engaged to superintend the erection of a house for the resident commissioner in Portsmouth dockyard, from the design of Mr. S. Wyat. Telford's good character and promising talent had secured for him the friendship of two families resident in his native district, the Pasleys and the Johnstones, and to their influence his early employment on important works is, in some measure, to be attributed. He was engaged upon various buildings at the Portsmouth dockyard for three years, during which time he became well acquainted with the construction of graving-docks, wharf-walls, and similar engineering works; and in 1787, having completed his engagements there, he was invited by the late Sir William Pulteney (a member of the Johnstone family) to take the superintendence of some alterations at Shrewsbury Castle. He therefore removed to Shrewsbury, where he was also employed to erect a new gaol, which was completed in 1793, and was subsequently appointed county surveyor, in which office (retained by him until death) he had to furnish plans for, and oversee the construction of, bridges and similar works. The first bridge which he designed and built was that over the Severn, at Montford, about four miles west of Shrewsbury, consisting of three elliptical stone arches, one of fifty-eight, and the others of fifty-five feet span. His next was the iron bridge over the Severn, at Buildwas, consisting of a very flat iron arch of a hundred and thirty feet span, constructed upon very superior principles to that erected a few years previously at Coalbrook Dale: Telford's object was rather to introduce the trussing principle of a timber construction than that of a stone arch. This bridge was built in the years 1795 and 1796. Forty smaller bridges were erected in Shropshire under Telford's direction.

The Ellesmere Canal, a series of navigations intended to unite the Severn, the Dee, and the Mersey, and extending altogether to a length of about one hundred and three miles, was the first great work upon which Telford was engaged, his satisfactory execution of the county works intrusted to him having led its projectors to select him as their engineer; and from this engagement, which commenced about 1793, in which year the act of parliament was obtained for the scheme, his attention was directed almost solely to civil engineering. The uneven character of the country occasioned many serious difficulties in the construction of this canal, and rendered necessary the execution of some works of astonishing magnitude, especially in crossing the valleys of the Ceriog, or Chirk, and of the Dee. In the former the canal crosses the river at an elevation of seventy feet by an aqueduct-bridge of ten arches, each of which is of forty feet span, in the construction of which some important deviations were made from the previous practice of engineers. It had been usual in such structures to form the bed for the canal of puddled clay confined in masonry, a practice which involved great expense, and some danger in time of frost, from the expansion of the moist puddle. The great elevation of the Chirk aqueduct would have increased the difficulty, but Telford abandoned the puddling system, and formed the

ned of the canal of flanged cast-iron plates resting upon walls built on the piers, and constructed the sides of masonry. This work was executed between 1796 and 1801, at a cost of 20,898*l*. The aqueduct-bridge over the valley of the Dee, called the Pont-y-Cysylte, is still more remarkable: it consists simply of a trough of cast-iron plates, securely flanged together, and supported by eighteen piers or pillars of masonry, the elevation of which is a hundred and twenty-one feet above low-water. These piers are solid to the height of seventy feet, above which they are hollow, with interior walls. The water-way in the cast-iron trough is eleven feet ten inches wide, of which four feet eight inches is covered by the towing-path, supported upon cast-iron pillars, so as to allow the water free play beneath it. The length of the aqueduct is about one thousand feet, and the height of the canal one hundred and twenty-seven feet above the Dee; and at one end of the aqueduct-bridge is a great embankment, fifteen hundred feet long, rising in parts to a height of seventy-five feet above the natural surface. These gigantic works were executed between 1795 and 1805, at a cost of 47,018*l*. In the locks of this canal Telford introduced cast-iron framing in lieu of timber; and in one instance, where the lock was formed in a quicksand, he made every part of that material.

The Caledonian Canal is another of Telford's principal works. In 1773 the commissioners of the forfeited estates in Scotland had engaged Watt to report on the practicability of a ship-canal along the valley called the Glen of Scotland, to be formed by connecting the lakes which form a series of navigable waters extending a great part of the distance; but although the report was favourable, it was not acted upon, and the scheme was deferred for some years by the restoration of the forfeited estates, through which the line would pass, in 1784. In 1801 however Telford was deputed by government to make a survey of the coasts and of the interior of Scotland, and to report generally upon desirable public works for the improvement of the country. In consequence of his reports Commissions were formed to carry out the proposed canal, and other improvements classed under the general title of Highland Roads and Bridges; and the services of Telford were engaged by both boards. The Caledonian Canal was opened throughout in 1823. Its construction was delayed by many untoward circumstances; and unfortunately its utility has not hitherto answered the expectations of its projectors. It forms however a noble monument of the skill of the engineer. The locks are stated by Telford to be the largest ever constructed at that time, being forty feet wide, and from one hundred and seventy to one hundred and eighty feet long; and one of them, at Clachnacarry, near Inverness, was made under circumstances of especial difficulty, the earth being a soft mud, into which an iron rod might easily be thrust to a depth of fifty-five feet. The means adopted for conquering this difficulty are fully detailed in the engineer's own narrative.

Of other canals constructed wholly or partially under Telford's superintendence it is sufficient to mention the Glasgow, Paisley, and Ardrossan (which was never completed to the length originally intended); the Macclesfield; the Birmingham and Liverpool Junction; the Gloucester and Berkeley (completed under his direction); the Birmingham, which was completely remodelled and adapted to the conduct of a very extensive traffic, by him; and the Weaver navigation, in Cheshire. He also constructed a new tunnel, 2926 yards long, 16 feet high, and 14 feet wide, at Harecastle, on the Trent and Mersey Canal, the original tunnel of Brindley having been found too small [TUNNEL]; and he executed many important works connected with the drainage of the fen country, especially of Bedford Level. On the Continent likewise he superintended the construction of the Gotha canal, in Sweden, a navigation of about one hundred and twenty English miles, of which fifty-five are artificial canal. This navigation rises one hundred and sixty-two feet from the Lake Wenern, at one extremity, to the summit-level, and falls three hundred and seven feet to the Baltic, at the other: the rise and fall are effected by fifty-six locks. The canal is forty-two feet wide at the bottom, and ten feet deep. Telford visited Sweden in 1808 to make the surveys and preliminary arrangements, and again in 1813, taking with him, under the sanction of the British government, several experienced workmen to instruct the natives in the works then in progress. Upon the completion of the canal a Swedish order of knighthood and other honours were conferred upon Telford.

The works executed by Telford under the Commissioners of Highland Roads and Bridges are of great importance. His survey was delivered to the Lords of the Treasury in 1802, and in the following year the Commission was appointed. Of the works committed to their superintendence Telford observes that 'the whole of Scotland, from its southern boundary, near Carlisle, to the northern extremity of Caithness, and from Aberdeenshire on the east to the Argyleshire islands on the west, has been intersected by roads; its largest rivers, and even inferior streams, crossed by bridges; and all this in the space of twenty-five years, under the same board, and (with some few exceptions) by the same individual Commissioners;' and all this was done under the direction of Telford alone. The practical operations under this Commission embraced about a thousand miles of new road, with twelve hundred bridges, in a mountainous and stormy region, of which five only, according to Telford's narrative, have required to be renewed. It should be explained that the operations of the Commission were not confined to the objects defined in its title, but embraced also the Glasgow and Carlisle road; the Lanarkshire roads; the improvement of several harbours, of which the principal are those of Peterhead, Banff, Frazerburgh, Fortrose, Cullen, and Kirkwall; and the erection of several Highland churches and manses under a parliamentary grant of 1823. Nor were these Highland churches and manses the only buildings in which Telford acted as an architect; he had, many years previously, erected a church at Bridgenorth, from his own design.

In the improvements of the great road from London to Holyhead, under another parliamentary Commission, appointed in 1815, Telford had a further opportunity of carrying into effect his system of road-making, of which an account is given under ROAD, vol. xx., p. 29, &c. This road, and the works connected with it, is probably the most perfect specimen of Telford's skill as an engineer, and appears to have been regarded by him with much satisfaction. The Menai suspension-bridge, especially, is a noble example of his boldness in designing and practical skill in executing a work of novel and difficult character: it is described under MENAI BRIDGE, vol. xv., p. 91, and SUSPENSION-BRIDGE, vol. xxiii., pp. 334-5.

Among the other works of Telford are many bridges of considerable size, in which he adopted the important principle of making the spandrils hollow, and supporting the roadway upon slabs laid upon longitudinal walls, instead of filling up the haunches with a mass of loose rubbish, which may press very injuriously upon the arch, and often proves of serious inconvenience when the masonry of the bridge needs any repair. He employed this mode of construction in a large arch, of 112 feet span, erected over the Dee, near Kirkcudbright, in 1805 and 1806, and in many subsequent bridges. In his 'Life' will be found particulars of the ingenious alteration of Glasgow old bridge, by the addition of a projecting footpath of cast-iron on each side, so as to leave the whole width of the stone structure for carriages; and of the new bridge designed by him for crossing the Clyde at Glasgow, and commenced in 1833; of the light and elegant Dean bridge, at Edinburgh; Path-head bridge, of five arches of 50 feet span, over a ravine about eleven miles south of Edinburgh; Morpeth bridge; Tewkesbury bridge, erected between 1823 and 1826, with a light iron arch of 170 feet span and only 17 feet rise; the Over bridge at Gloucester, and many others. The last-mentioned bridge has an arch of peculiar form, previously employed by Perronet in the Neuilly bridge. The general body of the arch is an elliptical curve of 150 feet span and 35 feet rise, but the external arch stones at the sides of the bridge form segmental curves of the same span, but of only 13 feet rise: the two arches are coincident at the crown, and are connected by a vaulted form on the haunches of the bridge. 'This complex form,' observes Telford, 'converts each side of the vault of the arch into the shape of the entrance of a pipe, to suit the contracted passage of a fluid; thus lessening the flat surface opposed to the current of the river whenever the tide or upland flood rises above the springing of the middle of the ellipse, that being at four feet above low-water; a precaution rendered necessary in this instance owing to the liability of the bridge to very trying floods.'

Telford executed some important harbour-works at Aberdeen and Dundee; but his most striking performance of this class is the St. Katherine Docks, London. Owing to the very limited space which could be obtained, it was necessary to construct these docks of irregular forms, and to adopt unusual arrangements respecting the warehouses; and these arrangements, combined with the admirable machinery employed, have reduced the time requisite for unloading a vessel in an astonishing degree.* There are two docks, communicating with the river by a tide-lock 180 feet long and 45 feet wide, with three pair of gates, so that either one very large or two smaller vessels may pass the lock at one time; and steam-engines are provided, capable of filling the locks in a few minutes by pumping water from the middle of the river, so that vessels are enabled to pass in and out of the docks with great rapidity so long as there is a sufficient depth of water to receive them outside the lock. The cast-iron turn-bridge over this lock is an excellent specimen of that kind of machinery, being easily worked by two persons at each end, although it supports a carriage-way 24 feet wide. These docks were constructed much more quickly than is usual for works of such magnitude, and more quickly than the engineer could fully approve, although he admitted the urgency of the case as a justification of a course against which he could not but enter his protest. One of the very latest engagements of Telford was the survey of Dover harbour, undertaken, in January, 1834, at the request of the duke of Wellington, as warden of the Cinque Ports, with a view to the adoption of measures to check the accumulation of shingle at the entrance.

In addition to the works which he executed himself, Telford was frequently applied to for his judgment upon important schemes, and in this way he made many reports to parliament. For many years he was employed to report upon all public works of engineering character for which loans were required of the Exchequer Loan Commissioners. Among his reports are several of considerable interest, especially upon proposed canals between London and Birmingham, and between the English and Bristol Channels, and on the supply of water to the metropolis, one of the last objects to which he devoted his attention. For some years before his death he had gradually declined as much as possible forming new engagements, and had made preparations for the publication of such a selection from his papers as might leave on record an authentic account of the important works in which for more than half a century he had been engaged. Having made arrangements with his executors for the completion of his work in case he should not live to finish it, he set about it with ardour, and had many of the plates completed, the manuscript in a very forward state, and arrangements made respecting the paper, type, &c. before his death. The book was not published until 1838, chiefly owing to the illness and death of Mr. Turrell, the engraver, and the difficulty of getting the plates completed. It forms a thick 4to. volume, entitled 'Life of Thomas Telford, civil engineer, written by himself; containing a descriptive Narrative of his Professional Labours;' and it contains a preface and supplement, by the editor, Mr. Rickman, and a very copious appendix of illustrative reports and other documents. The plates, eighty-three in number, constitute a companion volume, in large folio, to which is prefixed a fine portrait of Telford, engraved by W. Raddon, from a picture by S. Lane. From this work the materials of the preceding notice of his principal works are chiefly derived; and from the supplementary notice, by Mr. Rickman, and some other sources, are collected the following additional biographical particulars.

Before leaving his native district, Telford acquired some distinction as a poet. He wrote in the homely style of Ramsay and Fergusson, and contributed small pieces to Ruddiman's 'Weekly Magazine,' under the signature of 'Eskdale Tam.' He wrote a short poem, entitled 'Eskdale,' descriptive of the scenes of his early years, which was originally published in a provincial miscellany, subsequently reprinted at Shrewsbury, at the request of his friends, and afterwards inserted in the appendix to his Life. Another pleasing fragment of his composition is given at the end of the first volume of Dr. Currie's 'Life and Works of Burns,' published at Liverpool in 1800: it is an extract from a poetical epistle sent by Telford, when at Shrewsbury, to the Ayrshire poet, recommending him to take up other subjects of a serious nature, similar to the 'Cottar's Saturday Night.' He taught himself Latin, French, Italian, and German, so as to read them all with facility, and to converse readily in French; and he has left valuable contributions to engineering literature, in the articles Architecture, Bridge, Civil Architecture, and Inland Navigation, in Brewster's 'Edinburgh Encyclopædia,' in which work Mr. Rickman says he was a shareholder. He was well acquainted with algebra, but he held mathematical investigation in rather low estimation. In his early years he appears to have been tinctured with democratic opinions; but after seeing the excesses of the French revolution, he always studiously avoided conversing on political subjects. In all the relations of life he commanded respect and esteem; and he was particularly remarkable for his facility of access to the deserving, and especially for his ready communication of professional information to foreigners; a circumstance which, added to his connection with the Gotha canal and some other continental works, procured for him the highest respect on the continent of Europe. The Russian government frequently applied to him for advice respecting the construction of roads and canals; and the sixty-seventh plate in his atlas represents the details of a road designed by him from Warsaw to the Russian frontier. The emperor Alexander of Russia acknowledged his sense of his services on one occasion, in 1808, by sending him a diamond ring with a suitable inscription. Although he was not connected with the Institution of Civil Engineers at its formation, he accepted their invitation in 1820, and became their president; and from that time he was unremitting in his attention to the duties of the office, having become, by his partial retirement from business, a pretty regular resident in the metropolis. He ardently loved his profession, and was, observes Mr. Rickman, so energetic in any task before him, that all other motives became subordinate to it. He never married, and hardly had a fixed habitation until a late period of life. He was of athletic form, and reached the age of seventy without any serious illness; but in 1827 he was afflicted with a severe and painful disorder, after which he became subject to bilious attacks, under one of which he died, on the 2nd of September, 1834, at his residence in Abingdon Street, Westminster, at the age of seventy-seven. He was buried in Westminster Abbey. The acquisition of property was always a secondary consideration with Telford; and in certain cases, especially of abortive speculations, he was ingenious in finding arguments for giving his assistance gratuitously. Even in increasing his charges as his reputation and experience increased the value of his services, he seems to have been actuated chiefly by a sense of what was due to others in his profession, whose remuneration was in some degree dependent upon his own. After his mother's death he had few family connections to provide for, and he had a great objection to raising any individual above his station in life, which is stated by his biographer as his reason for not leaving his property to relations. His will, printed in the appendix to his 'Life,' provides for the payment of handsome legacies to many personal friends; of 2000*l.* to provide annual premiums to be given by the Institution of Civil Engineers; and of 1000*l.* each in trust to the ministers of Westerkirk and Langholm, for the purchase of books for the parish libraries. His scientific books, prints, drawings, &c. are bequeathed to the Institution of Civil Engineers. Telford became a fellow of the Royal Society of Edinburgh in 1803, and of that of England in 1827.

(*Life*, edited by Rickman; Chambers's *Scottish Biographical Dictionary*; *Annual Biography*, vol. xix.)

TELINGA or TELUGU LANGUAGE. [HINDUSTAN, p. 229.]

TELL, WILLIAM, a simple countryman of the village of Bürglen near Altorf in Switzerland, who lived towards the end of the thirteenth and during the first half of the fourteenth century. His early life is unknown, and his name would probably never have been heard of in history, if the tyranny of the Austrians had not called him from his obscurity. At the beginning of the fourteenth century, when Albert I. of Austria was endeavouring to suppress the spirit of freedom and independence in the three Waldstädte, Uri, Schwyz, and Unterwalden, and was using every means to add them to his family estates, he sent bailiffs (Landvögte)

* See, for an illustration of this point, a paper on 'The Docks,' forming No. LV. of 'London,' vol. iii. pp. 73-76.

into these cantons, who perpetrated the most flagrant acts of tyranny, and treated the people like a conquered nation. The principal men of the three Waldstädte, in 1307, formed a league, which was headed by Walter Fürst, Arnold von Melchthal, and Werner Stauffacher. William Tell, who had married a daughter of Walter Fürst, also belonged to the league, though without taking any prominent part in it. The object of these men was gradually and secretly to increase their numbers, and to seize on any favourable opportunity for delivering their country from its oppressors, and if possible without bloodshed. While the confederates were daily gaining new strength, Hermann Gessler of Brunegg, one of the bailiffs of Albert I., who had taken up his residence in the canton of Uri, after various other vexatious acts, caused the ducal hat of Austria to be raised on a pole in the market-place of Altorf, and commanded that every one who passed the pole should uncover his head as a token of respect for the house of Austria. William Tell with his little boy happened one day to pass the pole without paying any regard to the orders of the bailiff; and he was immediately seized and taken before Gessler. Tell had the réputation of being an excellent bowman, and Gessler devised a mode of punishment which should put his skill to a severe test. He ordered Tell's boy to be placed at a considerable distance from his father, and an apple to be fixed on his head. A crossbow and arrows were handed to Tell, who, without being observed, contrived to get two arrows, and he was ordered to shoot the apple from his own child's head. The tyrant added, that if he missed the apple, he should die. Tell succeeded in hitting the apple. Gessler had expected that Tell would kill or hurt his child, and in his disappointment he tried to find out some pretext for punishing the presumptuous peasant: he asked him why he had taken a second arrow? Tell boldly replied: 'It was intended for thee, if the first had hit my child.' The bailiff, delighted with this opportunity of satisfying his vengeance, ordered Tell to be bound and to be conveyed in a boat across the lake of Waldstädten to the castle at Küssnacht, the residence of Gessler, who himself accompanied his prisoner. When the boat was on the lake, a storm arose, which became so violent, that the rowers were unable to manage the boat, and proposed to Gessler to unfetter Tell and allow him to assist them, as he was known to be an experienced boatman and well acquainted with every part of the lake. Tell was freed from his fetters, and taking the rudder in his hand, he steered the boat towards a part of the rocky shore, where a flat shelf jutted out into the lake. When he was near this spot, he seized his bow, jumped upon the projecting rock, and with his foot pushed the boat back into the waters. The storm however was abating, and Gessler and his men were safely landed. Tell knew the road by which the bailiff had to pass to Küssnacht, and lay in wait for him in a narrow defile. When Gessler came, Tell shot him through the heart. This happened towards the end of the year 1307. The event was followed by a series of wars between the Swiss and the Austrians, which did not terminate till the year 1499.

The conduct of Tell was highly disapproved of by his friends, as they wished to avoid bloodshed, and were not yet prepared to carry their plans into execution. After this adventure Tell sinks again into his former obscurity, though he is said to have taken part in the battle of Morgarten, and to have perished, in 1350, in the river Schächen during a great flood.

Tell has been represented as a hero and a champion of liberty, by historians as well as by poets, but his conduct, if looked into more closely, will appear in a different light. His refusal to pay homage to the ducal hat of Austria was indeed owing to a noble independence of spirit; but his obeying the inhuman command of Gessler to shoot the apple from his child's head is repugnant to all paternal feelings, and a true hero would have aimed at the tyrant himself. He shot his enemy from an ambush, which, although in a measure an act of self-defence under the circumstances, yet in the manner of the execution was little better than murder.

But the truth of the story of Tell, notwithstanding its being commemorated down to this day by chapels and other public monuments, has been doubted by several modern historians; while others, and among them Johann von Müller, regard it as a genuine history. The doubts about its truth have arisen from the fact that a similar story is told in the Wilkina Saga, and by Saxo Grammaticus, of a Danish king Harold and one Toko. The same story is also told of one William Tell and a count of Seedorf who had extensive possessions in Uri, but must have lived early in the twelfth century. Another singular circumstance is that in the documents relating to the ancient Swiss confederacies, and published by Kopp at Luzern in 1835 ('Urkunden zur Geschichte der eidgenössischen Bünde') there is no mention of a Gessler among the bailiffs who resided in the castle of Küssnacht. For these and other reasons, Grimm and Ideler (*Die Sage vom Schusse des Tell*, Berlin, 1826) consider the whole story of Tell as fabulous. There are however facts which seem to confirm the historical truth of at least the groundwork of the story. It was not many years after the death of Tell that it became customary for annual processions to visit the spot where Tell had escaped from the boat, and in 1388 the canton of Uri built the celebrated chapel of Tell near the same spot, and it is stated that among the visitors of that year there were one hundred and fourteen who had known Tell himself. His adventure is moreover told to the same effect by all the chroniclers who wrote at or soon after the alleged time of the occurrence.

TELLER, WILHELM ABRAHAM, son of Romanus Teller, minister of St. Thomas's church at Leipzig, was born in that city, 9th January, 1734. So early as at the age of twenty-two he attracted the attention of the theological world by a Latin translation of Kennicott on the Hebrew Text; and after being for a year or two preacher at the Nicolai church, very unexpectedly received the appointment of professor of theology at Helmstädt, from the Duke of Brunswick, in 1761. On entering upon his new office, he published as an inangural disputation his 'Topice Scripturæ,' which was considered by Superintendant Bahrdt so heterodox in its opinions, that it was with difficulty he could be prevailed upon not to protest against Teller's appointment. Not deterred by this circumstance from expressing his own convictions, Teller published not long afterwards his 'Lehrbuch des Christlichen Glaubens,' a production that caused no little noise at the time, exciting violent disapprobation in some quarters, and obtaining him friends in others. Just before this work appeared he had been invited to accept the professorship of theology at Halle, then vacant by the death of Baumgarten, and he declined it out of regard towards his patron the Duke. But the persecution he continued to experience from those to whom his opinions had rendered him obnoxious made his residence at Helmstädt so disagreeable, that it was without the least reluctance he exchanged it, about three years afterwards, 1767, for Berlin, with the appointment of 'Obereonsistorial-Rath' and Dean of Cologne. While it removed him from their immediate attacks, the distinction thus conferred upon him also in some measure awed his opponents; and at the same time he himself was brought into intercourse with some of the most learned and distinguished characters belonging to the reign of Frederick the Great. He was so far however from neglecting his professional duties or relaxing his zeal, that he continued to apply to his theological studies with the same ardour as before, and was instrumental in promoting many beneficial plans connected with church matters and education in public schools. The vast number of sermons and various theological writings published by him, attest not only his industry, but his earnestness in the cause of genuine religion, although his rejection of the dogmas ingrafted upon Scripture afforded his enemies and those who lay greater stress upon speculative points than upon religious conduct and feeling an opportunity to decry him as very dangerous, heterodox, and unsound. 'Equally remote from all mysticism on the one hand, and from dry metaphysical philosophizing on the other, Teller,' says Küttner, 'addresses himself both to the reason and the heart, and while he touches the latter, carries conviction to the former.' Others have also spoken of him in very high terms, not only as a writer and teacher of religion, but as a man—one no less estimable in private life than in his public capacity, and as exemplifying in himself that conduct which he sought to enforce upon others.

Besides his German writings, Teller published not a few theological and critical dissertations in Latin, and continued to employ his pen almost up to the time of his death; for though he was greatly worn out in body, his

faculties continued active to the last. He died at Berlin, December 8, 1804. (Jörden's *Lexicon*.)

TELLERS OF THE EXCHEQUER were the holders of an antient office in the Exchequer. They were four in number: their duties were to receive money payable into the Exchequer on behalf of the king, to give the clerk of the pells (skins or rolls of parchment) a bill of receipt for the money, to pay all money according to the warrant of the auditor of receipts, and to make weekly and yearly books of receipts and payments for the lord treasurer. (4 *Inst.*, 108; *Com. Dig.*, tit. 'Court,' D. 4, 14, 15.) The office was abolished by act of parliament (4 & 5 Wm. IV., c. 15), together with that of the clerk of the pells and the several offices subordinate thereto, and a new constitution established, a comptroller-general of the receipt and issue of his Majesty's Exchequer being appointed to perform the duties of the four tellers. (4 & 5 Wm. IV., c. 15.)

TELLEZ, BALTHEZAR, a native of Lisbon, was born, according to the statement of M. Weiss, in the 'Biographie Universelle,' in the year 1595. Moreri states that he joined the Society of Jesus in the year 1610. In the eulogistic letter of Dom Francisco Manoel, prefixed to Tellez's 'History of Ethiopia,' he is said (at least this seems to be the writer's meaning, which his affected style renders rather obscure) to have studied ten years, and taught forty; to have paid attention to literature during the whole ten years of his career as student, but devoted two of them more especially to philosophy, and four of them to theology. He lectured upon *belles lettres* for twenty years, teaching in succession the most advanced literary classes in the Society's colleges at Braga, Evora, Lisbon, and Coimbra. He lectured two years on philosophy, but Manoel does not mention in what seminary. Lastly, Tellez was eight years professor of theology in the college of St. Antonio at Lisbon. At a later period he was appointed master of the house of the professed Jesuits in Lisbon, and ultimately provincial of the order in Portugal. He died in his eightieth year, on the 19th of April, 1675. The published works of Tellez are:—1, A compendium of philosophy, entitled 'Summa Universae Philosophiae, cum Quaestionibus quae inter Philosophos agitantur,' published at Lisbon, in folio, in 1642; at Paris, in two quarto volumes, in 1644; and at Lisbon, in four octavo volumes, in 1652: 2, 'Chronica da Companhia de Jesus da Provincia da Portugal,' in two volumes, the first published in 1645, the second in 1648, both at Lisbon: 3, 'Historia geral de Ethiopia a alta,' in one folio volume, at Coimbra, in 1660. He is also said to have left in MS. a history of the Society's labours in the East. The historical works of Tellez are of more value than his philosophical treatise. The History of the Jesuits in Portugal is a valuable contribution to the history of that accomplished and energetic order. The 'History of Ethiopia,' or, more properly, the history of the Jesuit-Missions in Ethiopia, is indispensable to any one who wishes to study the history or comparative geography of Abyssinia. The first book contains an outline of the geography of Abyssinia, of its political divisions, government, and statistics, as they existed from the time that the Jesuit missionaries first entered the kingdom till their expulsion under Facilidas. The remaining five books are chiefly occupied with the narrative of missionary enterprise, but contain important contributions to geography, the general accuracy of which has, on the whole, been confirmed by the testimony of later travellers. In the preface Tellez gives an account of the authorities from whom he has compiled his book, Manoel d'Almeyda, Affonso Mendes, Jeronymo Lobo, and Pero Pays; and he has availed himself of their information both with taste and judgment.

(The authorities for the statements in this sketch are the 'History of Ethiopia,' with the preface by Tellez himself, and the letter of Francisco Manoel prefixed to it; the articles on Balthezar Tellez, in the 'Bibliotheca Scriptorum Hispaniae' of Nicolao Antonio, in the 'Dictionnaire Historique' of Louis Moreri, and in the 'Biographie Universelle.')

TELLI'NA. [CONCHACEA, vol. vii., pp. 428, 429.]

TELLI'NIDES. [CONCHACEA, vol. vii., p. 428.]

TELLU'RIUM, a metal which was discovered in 1782 by Müller of Reichenstein, but its properties were more minutely examined by Klaproth sixteen years afterwards, and he gave it the name it now bears. It is a scarce metal. Its properties are the following:—its colour is silver-white, and it is very brilliant: it is crystalline and brittle, of a lamellar fracture, easily pulverized, and a worse conductor of electricity than antimony or bismuth. Its specific gravity, according to Klaproth, is 6·115, while Magnus makes it 6·1379. It is nearly as fusible as antimony, and at a high temperature it boils, and may be distilled. When strongly heated in contact with air, it burns with a lively blue flame, green at the borders, and forms a white vapour, which has an acid odour.

The principal ores of tellurium are the following:—

Native Tellurium.—It is found crystallized and massive. Primary form a rhomboid; occurs in minute six-sided prisms, the terminal edges of which are usually replaced. Cleavage parallel to the faces of the prism. Fracture indistinct. Hardness: scratches sulphate of lime, and is scratched by the carbonate. Easily frangible. Colour tin-white or steel-grey. Lustre metallic. Specific gravity 5·7 to 6·115.

Before the blowpipe very fusible, burns with a greenish flame, and is volatilized in a white vapour. It is soluble in hydrochloric acid.

Massive Variety.—Granular. Colour splendent tin-white. Lustre metallic. Opaque. Specific gravity 6·115.

It occurs in Transylvania.

Klaproth's analysis gives,—

Tellurium	92·55
Iron	7·20
Gold	0·25
	100·

Graphic Tellurium. Auro-argentiferous Tellurium.—Occurs crystallized. Primary form a right rhombic prism; occurs in attached flattened crystals, which are generally minute. Fracture uneven. Hardness: scratches talc, and is scratched by calcareous spar. It is brittle. Colour steel-grey. Lustre metallic. Opaque. Specific gravity 5·723.

Before the blowpipe it readily fuses into a globule, and is reduced to a metallic button of a bright yellow colour. Soluble in nitric acid, except a yellow metallic residue.

It occurs accompanying gold in narrow veins traversing porphyry at Offenbanya, and also at Nagyag, in Transylvania.

Analysis by

	Klaproth.	Berzelius.
Tellurium	60	62·
Gold	30	24·
Silver	10	11·3
Lead	..	1·5
	100	98·8

Berzelius found also a little sulphur, arsenic, antimony, iron, and copper.

Yellow Tellurium.—Occurs in imbedded crystalline laminæ. Primary form a right rhombic prism. Traces of cleavage. Fracture uneven. Hardness: scratches gypsum, and is scratched by calcareous spar. Rather brittle. Colour silvery-white, inclining to brass-yellow. Lustre metallic. Opaque. Specific gravity 10·678.

By the blowpipe melts into a metallic globule. Partly soluble in nitric acid.

It occurs at Nagyag in Transylvania, and in the Altai Mountains in Siberia.

Analysis by Klaproth:—

Tellurium	44·75
Gold	26·75
Lead	19·50
Silver	8·50
Sulphur	0·50
	100·

Black Tellurium.—Occurs crystallized, and in imbedded foliated masses. Primary form a square prism. Cleavage parallel to the terminal plane, in thin flexible laminæ. Fracture indistinct. Hardness: scratches talc, and is scratched by gypsum. Colour dark lead-grey. Lustre metallic. Opaque. Specific gravity 7·085.

Before the blowpipe is fusible on charcoal, and covers it with oxide of lead; reducible into a grey metallic globule, which eventually leaves a button of gold.

It is found at Nagyag and Offenbanya in Transylvania.

Analysis of the ore from Nagyag, by Klaproth:—

Tellurium	32·2
Lead	51·0
Gold	9·0
Silver	0·5
Copper	1·3
Sulphur	3·0
	100·

Brandes and Berthier have also analyzed this ore from Nagyag: their results differ considerably from the above, and also from each other.

Bismuthic Tellurium. Telluret of Bismuth.—Occurs crystallized in small six-sided prisms. Cleavage parallel to the base of the prism. Fracture indistinct. Hardness: scratches calcareous spar, and is scratched by fluor-spar. Colour steel-grey or zinc-white. Lustre metallic. Specific gravity 7·82.

Fusible by the blowpipe, and disengages the odour of selenium. Acted on by nitric acid, and the solution is precipitated by water.

It is found in Norway.

Analysis of Wehrle:—

Tellurium	34·6
Bismuth	60·0
Sulphur and traces of selenium	4·8
	99·4

We shall now describe the more important binary compounds of tellurium, beginning with

Oxygen and Tellurium.—It has been already mentioned that when tellurium is heated in contact with air, it burns, and a white vapour is formed: this is oxide of tellurium, or tellurous acid. It may also be obtained by the action of nitric acid on the metal; by adding water to the solution, part of the oxide is precipitated, and the remainder is obtained by evaporation to dryness. The properties of this substance are, that it is a white granular anhydrous powder, which slowly reddens moist litmus-paper, and is insoluble in water and acids. It is dissolved by a solution of potash or soda, and by fusing with their carbonates crystallizable salts are formed: when these are decomposed by acids, hydrated tellurous acid is precipitated, which, if washed with very cold water, and dried at a temperature not above 53°, may be preserved without suffering change, and is soluble in water, acids, ammonia, and the alkaline carbonates, which last it decomposes: the aqueous solution reddens litmus-paper: when zinc, tin, and some other metals are left in a solution of this acid, they deoxidize it, and metallic tellurium is precipitated in the state of a black powder. Its salts are called tellurites.

It is composed of—

One equivalent of oxygen	8
One equivalent of tellurium	32
Equivalent	40

Sesquioxide of Tellurium, or *Telluric Acid.*—This is obtained by fusing tellurous acid with nitrate of potash: by this it is oxidized completely, and the result is tellurate of potash: when chloride of barium is added to it, tellurate of barytes is precipitated, which, being decomposed by sulphuric acid, yields a solution of telluric acid; this yields hexagonal crystals of the acid: it acts but feebly as an acid, the dilute solution reddening litmus-paper with difficulty, and its taste is rather metallic than sour: the crystals contain water, two-thirds of which they lose at about 212°, and the remainder below a red heat becomes a mass of a fine orange colour, which is completely insoluble in water, either cold or boiling, or hot hydrochloric or nitric acids, or solution of potash. It is decomposed at a high temperature, and converted into a white powder, which is tellurous acid. Its salts are called tellurates.

It consists of

One and a half equivalent of oxygen	12
One equivalent of tellurium	32
Equivalent	44

Hydrogen and Tellurium.—When tellurium is alloyed by fusion with tin or zinc, and the compound is acted upon by hydrochloric acid, the hydrogen of the decomposed acid dissolves tellurium, and telluretted hydrogen gas is obtained. This gas has a smell somewhat resembling that of hydrosulphuric acid: it is soluble in water, forming a claret-coloured solution; and, as it possesses acid properties, though feebly, it has been called hydrotelluric acid. It decomposes many metallic salts, yielding an alloy of tellurium with the other metal. Chlorine, nitric acid, and the oxygen of the air, all take the hydrogen from the tellurium.

It consists of

One equivalent of hydrogen	1
One equivalent of tellurium	32
Equivalent	33

Chlorine and Tellurium form two compounds. When a feeble current of chlorine gas is passed over tellurium at a high temperature, the dichloride formed passes over as a violet-coloured vapour, which condenses at first into a black liquid, and eventually into a solid of the same colour. It is decomposed by the action of water into metallic tellurium, which is precipitated, and chloride of tellurium remains in solution.

It is comprised of

One equivalent of chlorine	36
Two equivalents of tellurium	64
Equivalent	100

The *Chloride of Tellurium* is obtained, as above stated, by the action of water on the dichloride, but is better procured by passing a larger quantity of chlorine over tellurium at a lower temperature than in forming the dichloride. It is volatile, and any excess of chlorine being separated by agitation with mercury and rectification, a white crystalline solid is obtained, which is composed of

One equivalent of chlorine	36
One equivalent of tellurium	32
Equivalent	68

Sulphur and Tellurium combine in two proportions: the sulphuret is obtained when hydrosulphuric acid gas is passed through a solution of chloride of tellurium, tellurous acid, or of a soluble tellurite. It is of a dark brown colour, and is soluble in a solution of potash. It is formed of

One equivalent of sulphur	16
One equivalent of tellurium	32
Equivalent	48

Persulphuret of Tellurium is obtained by mixing a solution of persulphuret of potassium with one of a salt of telluric acid. It is of a deep yellow colour; but it is a very unstable compound, for it speedily becomes black, and is converted into protosulphuret.

TELOPHO'NUS, Mr. Swainson's name for a genus of *Lanianæ* [SHRIKES, vol. xxi., p. 416], which he thus characterises:—

Bill more lengthened (than in *Lanius*), slightly hooked; the tooth smaller. Wings very short and rounded. Tail lengthened, graduated. Lateral toes free; the inner very slightly shorter than the outer.

Example, *Telophonus leucogrammicus.*

Bill of Telophonus leucogrammicus. (Sw., *Classification of Birds*, vol. ii.)

TELUGU or TELINGA LANGUAGE. [HINDUSTAN, p. 229.]

TEMANZA, TOMMASO, an architect who is better known by his writings relative to his art than by the buildings which he executed, was the son of an architect, and the nephew of another architect (Giovanni Scalfarotti), and was born at Venice in 1705. Having finished his mathematical studies in the school of Padre Niccolo Comini and the eminent Marchese Poleni, he was appointed—although then only twenty-two—one of the assistants in the Commission of Engineers, and in 1742 became the chief of that body on the resignation of Bernardino Zendrini, a few years before the latter's death (1747). His share in the hydraulic commission caused him for awhile to be involved in literary disputes, he having offended the people of Padua by a publication entitled 'Dell antico Corso de' Fiumi in Padova e suoi Contorni;' wherein he asserts that their ancestors had attempted to turn the

course of the Brenta. As an architect he had not many opportunities afforded him, for the period of Venetian grandeur and enterprise in art had passed away. He was however employed to execute one of the very few public edifices of any kind erected at Venice in the last century, namely the church of La Maddelena, a structure of the Ionic order, and which, though it may be said to be comparatively pure, is also somewhat feeble and insipid in design. His other principal architectural works are—the façade of Santa Margherita, at Padua; the Rotunda at Piazzolo, built at the expense of the Contarini family; and the bridge over the Brenta at Dolo. It is as a writer that Temanza is chiefly known, more especially by his 'Vite de' più Eccellenti Architetti e Scultori Veneziani,' 4to., Ven., 1778; which is one of the most copious as well as best-written works of the kind, not on account of the number of lives it contains, it being in that respect scanty, but for the unusual extent at which they are given. In fact several of them, Palladio, Sansovino, &c., had previously been published separately. Besides this literary production—an important contribution to architectural biography,—he published the 'Antichità di Rimini,' folio, 1741; and left behind him another work, 'Degli Archi e delle Volte, e delle Regole generali dell' Architettura Civile,' which was first edited in 1811. There are likewise a great many letters by him on architectural topics in Ticozzi's edition of Bottari's 'Raccolta di Lettere sulla Pittura,' &c.

Temanza died at Venice, June 14, 1789, and was buried in his own church of La Maddelena. There is a portrait of him in Gamba's 'Galleria d'Uomini Illustri,' to which work, and to Comolli's 'Bibliografia Storia Critica dell' Architettura Civile,' we are indebted for some of the particulars here given.

TEME. [SHROPSHIRE.]

TEMESWAR, THE BANAT OF, is one of the finest and most remarkable portions of Hungary, comprehending the counties of Torontal, Temes, and Krassova, and the German and Wallacho-Illyrian districts. These two districts are sometimes not considered as part of the Banat. The area of the whole is 11,340 square miles, and the population is said to be above a million; but there is no part of the Austrian empire the population of which it is so difficult to ascertain as that of Hungary. It is bounded on the north by the Maros, separating it from the counties of Arad, Csongrad, and Csanad; on the west it is separated by the river Theiss from the counties of Csongrad and Bacs, and the Czaisk district, and by the Danube from Slavonia; on the south by the Danube from Servia; and on the east by the Cserna, and the offsets of the Carpathians, extending from Transylvania, from Little Wallachia, and Transylvania. The Magyars comprehended it in the military district of Kant. It was a frontier province against the Wallachians, the Bulgarians, and the Turks. The latter however got possession of it in 1552, and retained it till 1716; when, in consequence of the victories of Prince Eugene, it was restored to Austria by the treaty of Passarowitz in 1718. Under the disorderly rule of the Turks, the country was overrun with banditti, so that many parts were nearly uninhabited and desert. Field-Marshal Count Francis Mercy d'Argenteau, who was appointed governor, and died in 1734, and Baron Engelshofen, his successor, exerted themselves to improve it by inviting numerous colonists from Germany, Italy, and France, building towns and villages, establishing manufactories, and erecting forts. But the Turkish war being renewed in 1737, many of these establishments were ruined, and a great number of the foreign colonists quitted the country. When peace was restored, numbers of Servians, Rascians, Macedonians, and Bulgarians, came from the Turkish provinces, bringing their property with them. In 1752 the government was changed from the military to the civil form, and, with the exception of a temporary check during the Seven Years' war, the progress of improvement in this province has been constant.

The Banat is remarkable for the great varieties of climate: in many parts the snow on the high mountains and in the deep ravines never melts, and in other parts it falls only in severe winters. A third part of the country is mountainous, and almost everywhere well watered. The ground which has been gained by draining the morasses on the banks of the Theiss and the Danube, and in the more elevated tracts by clearing the old forests, is extremely fruitful. In the middle of the two military frontier districts lies the most extensive sandy tract in the whole Austrian empire, in which there are however many oases. The principal points of the high mountains are Sarko, Gugu, Muraru, and Godjan; on the lower mountains there are vast forests and fine pastures. The principal rivers are the Danube, Theiss, Maros, Körös, Neray, Temes, and Bega. In 1748 and the following years canals were made in order to drain the marshes: the principal of these is the Bega canal, 75 miles in length, which traverses the whole of the counties of Temes and Torental, and is conducted into the Theiss. By the draining of the marshes, tracts which in the latter half of the last century were stagnant pools, the source of pestilential exhalations, are now covered with the finest corn-fields, or, where they have been imperfectly reclaimed, with crops of rice, and the salubrity of the country has been greatly improved. The protection which the mountains give against the east and north-east winds, and the mitigation which the north winds experience in traversing the great plain, raise the temperature to that of a southern country, and the rich soil yields abundant crops. The wheat and maize of the Banat are of the finest quality. Rice is extensively cultivated. Successful attempts have been made to cultivate cotton and silk, and in some parts a sweet wine is produced. There is no part of Hungary in which colonization has been attended with such favourable results by the settlement of industrious foreigners as the Banat, where there is still so much uncultivated land, and where, with the exception of some marshy tracts, the climate is very healthy. Mineral springs are frequent, but little use is made of them. Only those of Mehadia, which were known to the Romans by the name of *Thermæ Herculis*, are still much resorted to, especially by the Wallachian and Moldavian nobles. About this place, as well as in other parts of the Banat, Roman antiquities are frequently found. The population of the Banat, which is continually increasing by the accession of foreign settlers, consists chiefly of Wallachians, Rascians, Bulgarians, gypsies, Germans, Jews, French, Italians, and other foreign settlers: among whom, in the mountainous districts, the Wallachian language is prevalent; in the towns and colonised plains, the German; and in the districts of the military frontier, the Illyrian. The natural productions are horses, horned cattle, swine, wheat, maize, rice, flax, hemp, tobacco, fruit, wine, woad, madder, saffron, silk, timber, honey: game of all kinds and fish abound. The minerals are gold, silver, copper, zinc, and some iron. The gold is obtained by the gypsies, by washing the sand of the rivers. Between 4000 and 5000 workmen, chiefly Wallachians, are employed in the mines. The chief occupations of the inhabitants are agriculture and the breeding of cattle. There are no manufactures. The county of Temeswar, as has been stated, is one of the three included in the Banat, and needs no separate description. A circle of the county bears the same name.

TEMESWAR, the capital of the Banat and of the county, is a royal free city, situated in 45° 45′ N. lat. and 21° 10′ E. long., at the confluence of the Temes and the Bega, and on the Bega canal, in a part of the country which is rendered unhealthy by the stagnant waters in the vicinity. It is one of the strongest fortresses and one of the handsomest and most regular towns in the whole Austrian empire. While the town was in the possession of the Turks it consisted of only a few houses and an old castle, which is still habitable. When Prince Eugene made himself master of it in 1718, the strong fortifications were erected as a bulwark against the Turks, and the town was built in the modern style. The inner town, or fortress, is surrounded with triple walls and moats, and consists of large uniform stone houses, in straight, broad, well-paved streets. There are three gates, the Vienna, Peterwardien, and Transylvania gates, which are defended by strong blockhouses. The casemates are capable of containing 3000 men. Temeswar is the seat of the Roman Catholic bishop of Csanad, with his chapter and seminary, and of the schismatic Greek bishop of Temeswar: here too are the court of justice for the three counties, the offices of the governor of the fortress and of the commander of the Banat military frontier, a military academy, a great arsenal, and many other offices connected with the military and civil administration. The most remarkable buildings are—1, the old strong castle of John Hunyady, built of freestone, the

only relic of the antient Temes; 2, the churches, viz. the fine Gothic cathedral of St. George, belonging to the bishopric of Csanad, the cathedral of the schismatic Greeks, the Roman Catholic parish church, the churches of the Piarists, and of the seminary; 3, the elegant residence of the bishop of Csanad, the remarkably fine building in which the chapter resides, the house of the commander of the military frontier on the parade, the large and handsome county hall in the great square, the barracks, the military and civil hospitals, the synagogue, the Rascian town-hall, which contains the theatre and the assembly-rooms. Some of the churches were formerly Turkish mosques.

Temeswar has three suburbs, one before each gate, at the distance of 300 paces, with fine avenues of trees leading to them. Before the Vienna gate is the suburb Michala, inhabited by Wallachians, who have their own churches, and whose occupations are agriculture and the breeding of cattle. Before the Peterwardien gate is Josephstadt, an extremely pleasant suburb, with very broad straight streets, and trees planted in front of the houses. Many wealthy families reside here in the summer to enjoy the country, and formerly to avoid the fevers that usually prevailed in the town, but which have greatly abated since the surrounding marshes have been drained. The inhabitants of this suburb are Germans. The fine Bega canal passes through the middle of this suburb, and communicates with the Danube. Before the Transylvania gate lies the manufacturing suburb (*Fabriken Vorstadt*), so called from the great manufactories that were formerly established here, but most of which were broken up in 1738, when a Turkish war was apprehended; the suburb however retains its name. The Turkish merchants have their warehouses here. In this suburb there is a curious hydraulic engine, by means of which water is conveyed in iron pipes underground into the fortress: the inhabitants are chiefly Rascians. There is a considerable trade at Temeswar in the productions of the country, and some manufactures of cloth, paper, iron-wire, and silk. The population of the fortress is about 3000; and that of the whole town, including the suburbs, 13,000, besides the garrison.

(Brockhaus, *Conversations Lexicon;* Jenny, *Handbuch für Reisende in dem Oesterreichischen Kaiserstuate;* Thiele, *Das Königreich Ungarn; Die Oesterreichische National Encyclopädie;* Rohrer, *Statistik des Oesterreichischen Kaiserthums; Neueste Beschreibung von Ungarn, &c.;* Joseph von Hammer, *Geschichte des Osmanischen Reiches; Historisch-Statistischer Umriss von der Oesterreichischen Monarchie.* These two last works are anonymous. Hassel; Stein; Blumenbach; Hörschelmann; and Cannabich.)

TE'MIA, Le Vaillant's name for a genus of INSESSORES, or perching birds, which, Cuvier observes, M. Vieillot has changed into *Crypsirina*, and Dr. Horsfield into *Phrenotrix*, whilst M. Temminck arranges them under *Glaucopis*.

Cuvier remarks, that these birds have the carriage and tail of the magpies, an elevated bill with the upper mandible convex, and the base furnished with velvety feathers, nearly as in the BIRDS OF PARADISE. The species most antiently known is, he observes, the *Corvus varians* of Latham, which is of a bronzed green colour, and found in India and Africa. Cuvier places the genus between *Caryocatactes* [NUTCRACKER] and *Glaucopis*.

Mr. Swainson arranges *Crypsirina* in the subfamily *Glaucopinæ*, or Wattle-Crows, in his *Classification of Birds;* but in *Fauna Boreali Americana* he had made *Crypsirinæ* a subfamily. In the *Classification*, the genus is situated at the head of the *Glaucopinæ*, and is immediately succeeded by *Ptilostomus*, Sw.

Mr. Swainson thus characterises *Crypsirina*:—

Bill shorter than the head, much compressed; the culmen considerably arched, and curved from the base. Nostrils small, basal, concealed by incumbent feathers, which are either soft or setaceous. Wings short, much rounded; the primaries hardly longer than the secondaries. Tail feathers broad and obtuse. Feet moderate, arboreal. The middle toe and claw short, but as long as the tarsus; lateral toes unequal; hind toe and claw shorter than the tarsus. India.'

Bill of Crypsirina. (Sw.)

Crypsirina vagabunda (vagabunda) and *Temia* are among the species given as examples.

The first of these is the *Pica vagabunda* of Gould (*Century of Birds from the Himalaya Mountains*), and thus described by him:—

'The specific denomination of this bird is bestowed upon it in consequence of its peculiar habit of life. The *Pica vagabunda*, or Wandering Pie, unlike the typical pies, who remain constantly stationary in one neighbourhood, seeking for their food in its vicinity, wanders from place to place, travelling over a large space of ground, and not evincing a partiality for any particular situation. The shorter tarsus of this bird, indeed, and its more elongated tail, are indicative of trees being its most usual resort, where fruits and berries offer a supply of its natural food; whereas in the more typical *Picæ* the longer tarsus and more elongated beak fit them for digging in the ground, in which they almost solely seek for subsistence. This species is more widely distributed than any of its congeners, being found in considerable abundance all over India.

'The head, neck, and crest are of a smoke colour or a blackish-grey; the back light cinnamon; the centre of the wings grey; the quills black; tail grey; each feather being tipped largely with black; the under surface is pale-tawny; the beak and tarsi black. Length 16½ inches; beak 1¼; tarsi 1½; tail 10 inches.'

Pica Vagabunda. (Gould.)

Dr. Horsfield, who gives *Corvus varians* as the synonym of his *Phrenotrix Temia* (the *Chekitut* or *Benteol* of the Javanese), states that although not a rare bird in Java, his *Phrenotrix* is by no means familiar, and never approaches the villages and habitations like many others. 'It can only be observed near solitary hamlets situated in tracts recently cleared for cultivation, where its food is abundantly supplied by the insects contained in the rich mould, and by the wild fruit-trees about the skirts. In consequence of the shortness of the wings, its motions are slow: it is chiefly seen about noon sailing heavily through the air in a right line towards the trees surrounding the openings in the forest. The strength of the bill and of the claws shows its adaptation to feed both on fruits and insects.' (*Zoological Researches in Java.*)

Phrenotrix Temia. (Horsf.)

TEMNU'RUS. [TROGONIDÆ.]

TEMPE (*Τέμπη*, called also Thessala or Thessalica or Phthiotica Tempe) was the antient name of a beautiful valley in Thessaly, lying between Mount Olympus on the north and Mount Ossa on the south, near the mouth of the river Peneus, which runs through it. It is a narrow glen, not quite five miles long, opening on the east into a wide plain which extends to the Thermaic gulf. It forms the only break in the great chain of mountains by which Thessaly is enclosed on all sides. Antient traditions asserted that the great plain of Thessaly was at one time covered with water, which was at length discharged by the vale of Tempe, which was opened by a stroke of Neptune's trident, or (according to another legend) by the strength of Hercules. The appearance of the country has led modern travellers to accept the mythical story as meaning that the pass was opened at some period by a great convulsion of nature. The rocks which enclose it rise in precipices from the bed of the Peneus, and at the narrowest point these precipices approach so near each other that the road is cut in the face of them.

The Greeks reverenced Tempe as the place from which Apollo transplanted to Delphi his sacred laurel, and admired it as the most beautiful spot in their country. The most vivid description of it is that of Aelian (*Var. Hist.*, iii. 1). See also Ovid, *Metamorph.*, i. 569, &c.; Livius, xliv. 6; Plin., *Hist. Nat.*, iv. 8; Cramer's *Greece*, i., p. 379; the Tours of Clarke, Holland, Dodwell, and Gell; and Thirlwall's *Hist. of Greece*, i., p. 5.

TEMPERAMENT (*temperamentum*, *κρᾶσις*) is a vague and unsatisfactory term, but still it is one which, as Dr. Mayo observes (*Pathology of the Human Mind*, London, 12mo., 1838, Append., p. 162), 'has for many centuries been found a convenient generalization; and, unless we propose to sacrifice knowledge at the altar of logic, we must still be contented to use this or some other equally indefinite term.' The word means literally *a tempering*, or *mixing together*, and may be defined to be a peculiar state of the system common to several individuals, which results from the various proportions in which the elementary parts of the human body are *mixed up together*, and which gives rise to a tendency to certain phenomena. There is besides in each individual a further peculiarity of combination, which serves to distinguish his temperament from that of any other person, to whom however he may in other respects bear a great resemblance. This individual temperament is called an *idiosyncrasy* (i.e. *a peculiar mixing together*), and, as the two words are sometimes confounded, it may be useful to have pointed out the distinction between them. All the different systems of organs in the human frame are accurately adjusted to each other, so as to produce one harmonious whole. If the disproportion be too great, disease ensues; but there are many gradations, compatible with health, where yet this disproportion is very observable. The predominance of any particular system of organs modifies the whole economy, impresses striking differences on the results of the organization, and has perhaps almost as great an influence on the moral and intellectual as on the physical faculties. This predominance establishes the temperament: it is the cause of it, and constitutes its essence. The antients paid considerable attention to the subject of temperaments, and pointed out various peculiarities in the constitution and actions of the human body, which have been seen so far to coincide with general observation, that their nomenclature has continued in very general use even to the present day, although the hypothesis on which it was founded is universally discarded. They described four temperaments corresponding to the four qualities of Hippocrates—hot, cold, moist, and dry. It was supposed that there were four corresponding primary components of the human body, namely, blood (*αἷμα*), phlegm or pituita (*φλέγμα*), and the two kinds of bile (*αἱ δύο χολαί*), yellow bile (*ξανθὴ χολή*), and black bile or atrabilis (*μέλαινα χολή*); and the preponderance of one or other of these components in different persons produced the different temperaments. These four primary principles of living bodies were supposed to be compounded of the simple elements or qualities of nature thus: hot and moist produce blood; cold and moist, phlegm or pituita; hot and dry, yellow bile; and cold and dry, black bile. Bodies in which blood superabounds are of the sanguine temperament; if phlegm is in excess, the phlegmatic temperament is developed; if yellow bile, the choleric; and if black bile, the melancholic or atrabilious temperament. The following is the description of the different temperaments given by Paulus Aegineta (*De Re Medica*, lib. i., cap. 61), in Mr. Adam's Translation (London, 1834, 8vo.):—'Those bodies which are of a hotter temperament than the moderate will have their teeth earlier than usual, and will grow in like manner. They feel warmer to the touch, and have less fat; they are of a ruddy colour, and have their hair black and moderately thick, and their veins are large. But if such a one be also fat and brawny, and have large veins, he is fat from habit, and not from nature. The following are the symptoms of a cold temperament: such bodies appear cold to the touch, are without hair, and are fat; their complexion, like their hair, being tawny. But when the coldness is great, they are pale, leaden-coloured, and have small veins; and if lean, this does not proceed from nature, but habit. The dry is harder and more slender than the temperate, the hardness indeed being inseparable from the dry temperament; but leanness not only follows the connate temperaments, but also those which are acquired by long habit. It is peculiar to the humid temperament that the body is oppressed by things of a moist nature. The warm and dry temperament, in other words, the *choleric*, is extremely shaggy, having the hair of the head in early age of rapid growth, black, and thick; but in after-life baldness follows. The veins are large, as are likewise the arteries, which beat strongly. The whole body is firm, well articulated, muscular, and without obesity; and the skin hard and dark. When the temperament is cold and humid, or *phlegmatic*, the chest is narrow, and, like the rest of the body, without hairs; the skin is soft and white, and its hairs somewhat tawny, especially in youth; and such persons do not get bald when they grow old: they are timid, spiritless, and inactive; their veins are invisible; they are gross and fat; their muscles and legs are feeble, and their joints ill-formed; and they are bandy-legged. But should the humidity and coldness increase, the colour of their skin and hair becomes tawny, or, if they increase still more, pale. The hot and humid, or *sanguine*, temperament is softer and more fleshy than the proper, and, when it increases much, is subject to putrid disorders; but if it be only a little more humid and much hotter than the moderate, the bodies of such persons are only a little more soft and fleshy than the moderate, but they are much more hairy and hotter to the touch. But if the cold and dry grow equally together, and form the *melancholic* temperament, such persons have naturally their bodies hard, slender, and white, with fine muscles, small joints, and little hair; and they are cold to the touch. Although slender, fat is mixed with their flesh. The colour of their hair is correspondent to the degree of constitutional coldness. As to disposition of mind, they are spiritless, timid, and desponding. To say all in a word, with regard to the compound temperaments, they are always to be distinguished by the marks of the prevailing quality.'

The due admixture of these different qualities was supposed to constitute the best form of temperament or constitution (*εὐκρασία*), of which the following is Paulus Aegineta's description (*Ibid.*, i. 60):—'That man is in the best temperament of body when it is in a medium between all extremes, of leanness and obesity, of softness and hard-

ness, of heat and cold, of moisture and dryness; and, in a word, who has all the natural and vital energies in a faultless state. His hair also should be neither thick nor thin, neither black nor white. When a boy, his locks should be rather tawny than black, but when an adult, the contrarywise.'

Further information respecting the opinions of the antients on the subject of the temperaments may be found in the treatise of Hippocrates, *De Natura Hominis*, tom. i., ed. Kühn; in Galen's works, *De Elementis ex Hippocrate*, tom. i., *De Temperamentis*, tom. i., *De Optima Corporis nostri Constitutione*, tom. iv., *De Sanitate Tuenda*, lib. v., tom. vi., and his *Ars Medica*, tom. i.; Oribasius, *Synopsis*, lib. v., cap. 43, sq.; Aëtius, *Libri Medicinales*, lib. iv., cap. 53, sq.; Haly Abbas, *Theor.*, lib. i.; Averroes, *Collig.*, lib. vi.; Alsaharavius, *Theor.*, tract. vi.; and Avicenna, *Cantica*.

After the revival of letters, this fourfold division was adopted in its most essential parts by all the most eminent physiologists. Stahl ingeniously adapted it to the modern doctrines of the humoral pathology; and even Boerhaave, although he increased the number of the temperaments to eight, and relinquished the erroneous opinions of Hippocrates and Galen respecting the constitution of the blood, yet he still derived the characters of his temperaments from the principles of the humoral pathology, and supposed them to be formed merely by different combinations of the four cardinal qualities. Many late physiologists have been inclined to doubt whether the external characters associated with the four temperaments are real and constant signs of diversity in bodily structure, and enable us to distinguish the principal varieties of constitution which exist. Several attempts have accordingly been made to define in a more satisfactory manner the peculiarities of organization and the resulting varieties of predisposition, which are chiefly interesting with regard to pathology. Hoffmann and Cullen have indeed retained the old division, supposing that the theory of the antients as to the peculiarities of constitution was founded originally upon facts, though subsequently combined with an erroneous theory. Haller seems to have been the first who decidedly opposed the antient doctrine, not only by showing that there was no foundation for the varieties of the temperaments in the peculiar nature of the fluids, but by substituting in their place the vital actions of the system. Darwin proceeded upon the principle of Haller; and, in conformity with the hypothesis which he adopted of reducing these actions to the four heads of irritation, sensation, volition, and association, he formed four temperaments in which these qualities were supposed respectively to prevail. The only attempt however to improve upon the Hippocratic theory and division which has been attended with any degree of success is that by Dr. Gregory, who to the four temperaments of the antients added a fifth, which he called the *nervous*, and bestowed upon three of the others the new appellations of the *tonic*, the *relaxed*, and *muscular* temperaments. Dr. Prichard however restricts the number to four, and designates them by their original names; remarking that only four strongly marked diversities of external character present themselves to observation; that the nervous temperament is not so distinguished; and that therefore, as this is an essential part of the original scheme for the distribution of temperaments, the improvement proposed by Dr. Gregory is lame and defective. These four varieties then of external character really indicate, more or less constantly, well marked differences of constitution, and likewise of morbid predisposition. There is no doubt that persons having the complexion and other signs of the sanguine temperament are more liable to certain classes of disorders than the phlegmatic or melancholic, while the latter have their own peculiar tendencies. The sanguine, having a fully developed vascular structure, and therefore a vigorous circulation of blood, a warm skin, and a high degree of organic sensibility, are more liable to sudden and powerful impressions from external agents than those of more languid vital functions. They are subject in a greater degree to severe inflammatory disorders, and disorders of this class are in them more acute: they bear however, better than persons of more languid habit, evacuations of blood and the other measures which are found to be the proper remedies for these diseases. The greater fulness of blood-vessels, of those at least which are near the surface, the greater warmth of the skin, and the florid complexion of the sanguine, afford reason to believe that the designation given to this temperament is not wholly unfounded. We likewise find that sanguine persons are more subject to hemorrhages (to those at least which are termed *active*) as arising from excess in the force of circulation through the arteries. Individuals of the phlegmatic temperament are predisposed to disorders arising from, or connected with, a low degree of vital energy. Local congestions of blood arising independently of general excitement come under this category. Glandular and tubercular diseases take place in bodies weak in the structures connected with the vital functions, and are perhaps more frequent in the phlegmatic than in other temperaments. Inflammatory complaints, when they attack the phlegmatic, are less acute and more disposed to terminate in chronic diseases than are those of the sanguine constitution, when at least the latter have been treated by appropriate remedies. The relations of the choleric to the melancholic temperament are similar to the relations which the phlegmatic bears to the sanguine; the former displays greater vigour, both in health and disease, than the latter. The choleric and sanguine, when affected by diseases of the nervous system, have complaints of greater violence and acuteness; mania or raving madness belongs particularly (according to the observations of M. Esquirol and many others) to these constitutions. The melancholic temperament is most prone to monomania, attended with depression and melancholy illusions. Hypochondriasis much more frequently affects the phlegmatic and melancholic, though it is occasionally observed in persons who have some of the external characters of the sanguine temperament. The most severe cases of hypochondriasis, adds Dr. Prichard, and those which approached most nearly to the character of melancholia, have certainly occurred in individuals of a dark leaden complexion, fixed and sullen aspect, and lank coal-black hair.

But it is not merely on the body, both in its healthy and morbid state, that the temperament exerts an important influence; the relation of the different forms of physical organization to the intellectual, and even to the moral, faculties is equally marked and apparent. The relation of mental peculiarities to the structure of the body has been observed by medical authors of every age, and it has been stated and explained in different ways. Hippocrates said that 'the soul is the same in all men, but that the body is different in different individuals. The soul is ever like itself both in greater and in less, for it undergoes change neither by nature nor by necessity; but the body is subject to continual alterations.—The affections of the mind depend upon the body; there are many states of the latter which sharpen, and many which obtund it.' (Hipp., *De Victûs Ratione*, lib. i., § 21, tom. i., p. 650.) Democritus, in a letter said to have been addressed by him to Hippocrates, asserted that 'the intelligence of the mind depends greatly on the body, the diseases of which obscure the mental faculties, and draw the latter into consent.' (Hipp., *Epist.*, tom. iii., p. 824.) Among the writings of Galen there is a treatise entitled *Quod Animi Mores Corporis Temperamenta sequantur* (tom. iv., ed. Kühn), written expressly to establish the connection between the passions and desires of the mind and the temperaments, wherein he has handled the subject very ingeniously and has delivered many profound views of the animal economy. But it is in the works of modern writers that we find this doctrine most fully developed, and made a foundation for a division of human characters. According to Hoffmann, the choleric temperament by peculiarity of organization disposes men to precipitate and impetuous conduct, to anger, audacity, impatience, temerity, quarrels, sedition, and the like. On the other hand the slow progress of the blood through the vessels of the meninges, which is the result of its crassitude in melancholics, renders such persons timid, slow in business, anxious, suspicious, with difficulty of forming or uttering opinions. The sanguine by a happier temperament are rendered cheerful and free from care. A too abundant serosity causes the phlegmatic to be lazy, somnolent, and torpid. Certain temperaments qualify men for particular situations in life. Melancholic men, says Hoffmann, should be the king's ministers and counsellors; choleric persons should be appointed generals, foreign ambassadors, orators, and conductors of all business requiring energy and dispatch; and it was with some such impression concerning the peculiar qualities of this temperament that Napoléon, after c m-

plaining of its inconvenient effects in deranging his temper, is said by M. Ségur to have added, 'Cependant sans cette maudite bile on ne gagne pas de grandes batailles.' Sanguine men, continues the writer above mentioned, are fit for courtiers; but individuals who have the misfortune to be of the phlegmatic temperament, being quite incompetent to any elevated condition, must be made common soldiers or labourers, and condemned to the lowest employments. (*De Temperamento Fundamento Morborum*, § 10, quoted by Dr. Prichard.) It is extremely improbable that an opinion should have held its ground for so many ages among men of observation, especially on a subject requiring no abstruse research, without some foundation at least in fact. The doctrine of temperaments is true to a certain extent, and has ever been confirmed by an appeal to experience. States of the mind are so connected with affections of the body, that it is impossible for any person who considers all the physiological facts that present themselves in connection with this subject to doubt that with each temperament particular mental qualities must be associated, although it is manifest that many writers have indulged their fancy on this subject, and have gone into more full and minute details than experience will establish. The same may be said of phrenology, with which science the doctrine of the temperaments is in this point of view closely connected, as modifying in some degree the intellectual and moral qualities depending on the organization of the brain. This very interesting subject is discussed at some length in Dr. Prichard's article on 'Temperament' in the *Cyclopædia of Practical Medicine*, from which most of the preceding observations are taken. See also Bostock, Richerand, and Müller's works on Physiology, and other writers there quoted.

TEMPERAMENT. [Tuning.]

TEMPERATURE. [Atmosphere; Climate; Isothermal Lines.]

TEMPERATURE OF THE EARTH. [Geology, p. 133.]

TEMPERATURE. It is intended under this head to notice the law of the variations of temperature on the earth so far only as to indicate its analogy with that of the variations of terrestrial magnetism; the formulæ expressing the mean temperatures at different places being, as yet, very far from affording satisfactory results, and observations being too few to serve as a basis for correct theory. In Climate there are given some general observations concerning the distribution of heat at the surface of the earth, and under Isothermal Lines there will be found the estimated values of the mean temperatures at the equator and at the geographical north pole. With respect to the former, it may be said to have been tolerably well determined, and to be nearly uniform quite round the world; but the mean temperature at the pole can only be surmised from the uncertain evidence afforded by an application of the formula of temperature which has been found to hold good in the north of Europe, and a correction founded on an estimated amount of the frigorific influence of ice: even the determination thus obtained is rendered still further uncertain by the fact that the decrease of temperature in proceeding from the equator northwards is different on meridians which differ considerably in longitude.

Before this difference of temperature on the same parallel of latitude in the old and new continents was known or regarded, a simple formula was thought sufficient to express the temperature at any parallel of terrestrial latitude. The celebrated Tobias Mayer, from such mean temperatures as had in his time been observed, found that the temperature t (on Fahrenheit's scale) at any place might be represented by $T-52° \sin.^2 L$, where T is the mean temperature at the equator, and L the geographical latitude of the place; and in 1819 M. Daubuisson ('Traité de Géognosie') proposed the more accurate formula $t=27° \cos.^2 L$ (centigrade scale); which being adapted to Fahrenheit's scale, considering the mean temperature at the equator to be 81°, becomes $32°+49° \cos.^2 L$. This formula has been found to serve for temperatures in Europe as far north as the latitude of 60°; but beyond that parallel it is useless, and it supposes the temperature at the geographical pole to be 32°, which is much too high.

From above 4000 observations which were made by Sir Edward Parry, it is found that in Winter Harbour, in 74° 45′ N. lat., and in long. 250° (110° W. long.), the mean temperature is as low as 1·33°; and from above 600 observations at Spitzbergen (78° N. lat.) Mr. Scoresby found the mean temperature to be 16·99°: a mean temperature of 17° is also found on the American continent, in 65° N. lat.; and hence it may be inferred that, between the parallels of 65° and 78°, and near the meridian of Winter Island, there exists a pole of minimum temperature. The mean temperatures of places in the eastern parts of Asia have not been well ascertained; but since at North Cape in Lapland the mean temperature is that of freezing water, and in Siberia, as low as the parallel of 60° N. lat., the surface of the ground is constantly frozen, it is evident that the isothermal line of 32° must form a curve about some point as a focus in the northern part of the Asiatic continent: hence, for determining the mean temperature of any place, no formula which does not involve the position of the place with respect to the two foci of coldness can be expected to satisfy the phenomena.

This circumstance has suggested to Sir David Brewster the formula $T=(t-\tau) \sin.^n \delta \sin.^n \delta'+\tau$ for the mean temperature at any place: T being that temperature, t the mean temperature at the equator, τ the temperature at each of the foci of coldness, and δ, δ', the distances in degrees between the given place and those foci. A corresponding expression will serve to determine the number of vibrations which would be performed by a magnetized needle in a given time if t and τ be made to represent the numbers performed, in an equal time, at the magnetic equator and at either of the poles of magnetic intensity: the exponent n, both for temperature and intensity, is to be determined by means of observations, and Brewster considers that the fraction $\frac{1}{2}$ may be the value of it in the formula for temperature.

The similarity of character which is presented by the isothermal lines and those of magnetic dip and intensity, with respect to two polar points in one hemisphere of the earth, and the fact that the poles of temperature and magnetism lie nearly in the same parts of the world, cannot fail to suggest the idea that there may be a connection between the temperature and magnetism of the earth. It is generally believed, also, that the temperature of the western parts of Europe is now higher than it was nearly two thousand years since; and it has, hence, been inferred that the poles of minimum temperature perform revolutions about the geographical pole of the earth, so that the terrestrial meridian on which the greatest cold prevails gradually changes its position. If this opinion be well founded, the circumstance will afford another argument in favour of the hypothesis which assigns to the temperature and magnetism of the earth an intimate connection with each other, by its correspondence to those motions of the poles of magnetic dip which have been adduced from observations by M. Hansteen. [Terrestrial Magnetism.]

As the mean temperature at the surface of the earth is an element of great importance in the present state of physical science, it has been strongly recommended to travellers and persons making distant voyages, if they are to remain only a few days at any place, that they should, on arriving, lose no time in burying in the earth, to the depth of from three to twelve feet, according to the power of penetrating into the soil, bottles filled with water, or with spirits, if there should be any danger of water freezing. These bottles should be packed in boxes stuffed with woollen cloths, pounded charcoal, or any other non-conducting material, and should be allowed to remain underground till the time of departure, in order that they may acquire, as accurately as possible, the temperature of the ground. On being taken up, the temperature of the liquid should be ascertained by a good thermometer inserted in the bottle.

TEMPERATURE OF PLANTS. The living processes by which heat is so evidently developed in animals go on, though much less actively, in plants, and give to them a peculiar temperature, independent of the air in which they live. The periods at which an increase in the temperature of plants has been most evidently observed are those of germination, flowering, and impregnation; but it is only because those chemical changes which produce heat are more active during the performance of those functions that the heat becomes more evident. The great cause of the development of heat in animals is the union or combustion of carbon with oxygen, which is constantly taking place during the process of nutrition in the various tissues of

the animal body. The same thing occurs during the general growth of the plant: a certain quantity of carbonaceous matter is contained in the sap of the plant, which, coming in contact with oxygen in the tissues of the plant, unites with it, forms carbonic acid, and heat is developed.

That a development of heat took place during the growth of plants was proved by Hunter, who placed a thermometer within the stems of several trees, and found that their temperature was always above that of the atmosphere. These experiments were followed up by Salomé, Hermstadt, and others, who confirmed the experiments of Hunter. De Candolle however supposed that this increase of temperature depended on the sap which was pumped up from the soil; but this theory will not explain the phenomena of heat observed during the growth of plants, nor is it at all applicable to its occurrence during germination, which is evidently an analogous process.

Schubler, Neuffer, Nau, and Goeppert have conducted a variety of experiments on the temperature of plants. They found that in winter the parts that were not frozen had a higher temperature than the surrounding air: this was much more remarkably the case in spring; but in summer the temperature of the plant was mostly below that of the surrounding air. These experiments are in accordance with what we know to be the law of the development of heat in more highly organized textures. In winter the vital processes of plants are slow or almost suspended; hence the small increase of temperature at that season. In the spring the process of growth is most rapid, and there is the greatest conversion of nutritive matter into the structure of the plant, and it is at this season of the year that the temperature of the plant is highest above the surrounding air; but in summer the heat of the air becomes greater, and the temperature of the plant is kept under that of the atmosphere by the exhalation which is constantly going on from all parts of its surface.

In the development of heat during germination the changes that take place are more evident. The starch or fecula surrounding the young plant is converted into sugar, and this process takes place through the separation of carbon and oxygen in the form of carbonic acid, which, during their union, give out heat. A familiar instance of this process is seen in the increased heat of the growing barley previous to its being dried to form malt.

The increase of heat is more evident still in the flowering of plants, which, according to Dunal, results from the conversion of a certain portion of starch or fecula in the disk and petals of the plant into sugar, for the nutrition of the anthers and ovules of young plant. The increased heat of the flowers of plants during certain stages of their development was first observed by Madame Hubert in Madagascar, who, being blind, was the more dependent on the organ of touch; and in handling plants she found that the Arum cordifolium was much warmer than others. This led Bory St. Vincent to pursue a series of experiments on this plant, in which he found a very high degree of heat developed during its flowering, which was sometimes 7° higher than the surrounding atmosphere. The flowers of the Arum tribe are very favourably constructed for the development and retention of heat; but all flowers, previous to the full development of their anthers and the function of impregnation, undergo these changes, which produce an increase of temperature.

(Meyen's *Pflanzen Physiologie*, band ii.; and Lindley's *Introduction to Botany*.)

TEMPERING OF STEEL. [STEEL.]

TEMPESTA, ANTONIO, a celebrated Italian battle and animal painter and engraver, was born at Florence in 1555. He became the scholar of John Strada or Stradanus, a Fleming, who was settled at Florence in the employ of the grand-duke, and who assisted him in the battles which he painted in the old ducal palace. Tempesta, after painting some years with Strada, whom he surpassed in many respects, visited Rome, and was employed by Gregory XIII., in the Vatican, where he painted, in small figures in fresco, the Translation of the Body of St. Gregory of Nazianzus, and some other subjects, which acquired him a great reputation among the artists and virtuosi of Rome, and procured him constant occupation from the Roman nobility. He executed several good works for the Cardinal Alessandro Farnese, at his villa at Caprarola, and some at Bassano for the Marquess Giustiniani. Tempesta resided chiefly at Rome, and died there in 1630, aged seventy-five. His reputation rests now almost entirely upon his etchings, although in his time he had a great name also as a painter. Lanzi terms him the first Italian who ever attained distinction in landscape and animal painting, and considers him at this period to have been unrivalled in his own style in Italy; he was however surpassed afterwards by Cerquozzi and Borgognone. Horses were his favourite subjects, and he excelled in battles, processions, cavalcades, hunts, and various field-sports. His designs, particularly his etchings, are remarkable for their spirit and boldness of conception, but they are at the same time coarse and heavy, and careless in their execution. He painted generally small figures; in large ones he was not successful, and he seldom attempted them; he however occasionally prepared large cartoons for tapestries, in the style of his master Strada. Tempesta's chief works in painting, besides those in the Vatican, already noticed, were a Slaughter of the Innocents, in the Church of San Stefano Rotondo, at Rome; and two great cavalcades and state-processions, executed for the Cardinal Scipione Borghese, as friezes around the loggie of his palace on Monte Cavallo (afterwards Palazzo Bentivoglio), which, according to his biographer and contemporary Baglione, were alone sufficient to have ensured him a lasting reputation if he had never painted anything else. One represented a state procession of the Pope; the other, one of the Grand Turk. Tempesta has executed etchings of both these subjects. His invention was amazingly fertile; he has been equalled by few artists in the number of his designs. According to Gandellini, Tempesta etched 1510 plates, and about 500 have been engraved after him by other masters. He also engraved after other masters himself; he executed some battles, and 40 plates of the Spanish story of 'The Seven Twin Sons of Tara,' after Otho Venius: Filibien, in his 'Entretiens sur les Vies des plus célèbres Peintres,' has related the story at length, and has described the subject of each plate.

Tempesta's style of etching is peculiar and not agreeable; and although his designs are bold, and contain many grand parts, they are heavy, his style of design gross, his compositions generally confused, and his light and shade disposed without taste: his most valuable designs are his hunts and field-sports, and his studies of horses. Of his other pieces the following are among the best and the most celebrated:—

A set of 150 illustrations to the Old Testament, known as 'Tempesta's Bible;' 15 large figures of Christ, the Virgin, and the Apostles; a very large plate of the Victory of the Jews over the Amalekites, marked 'Hebraeorum Victoria ab Amalechitis reportata,' the composition of which is spirited, but very confused; the Life of St. Antony, in 24 plates; 150 small plates from Ovid's 'Metamorphoses;' 13 of the Labours of Hercules; and 7 of the Seven Wonders of the Antient World. He etched many cavalcades and processions, and engraved also large plates from the following statues—they are however executed too much in his own style to be faithful representations of the originals:—Castor and Pollux, and the horses on Monte Cavallo, and the equestrian statue of Marcus Aurelius on the Capitol, at Rome; the equestrian statue of Cosmo I., by John of Bologna, at Florence; that of Henry IV. of France, at Paris, which was destroyed in 1792; and one of Henry II. of France. The last statue however never existed, for a figure of Louis XIII. was placed upon the horse which was originally designed for a statue of Henry II., who was killed at a tournament. Tempesta's print bears the following inscription: 'Effigies equi aenei operis Dan. Ricci, Volterrani, fieri jussit Reg. Maria ob memor. Reg. Henrici II. F. M. sui viri, qui obiit in torniamentis.'

A spirited design of the Battle of the Centaurs and the Lapithae, by Tempesta, was cut in a large size in wood, by Jeronime Parabole. As a man Tempesta appears, according to his contemporary Baglione, to have been highly accomplished in every respect, and to have been universally esteemed by his companions. There is a long list of the works of Tempesta in Heincken's 'Dictionnaire des Artistes,' &c., and in the 'Peintre Graveur' of Bartsch.

TEMPESTA, CAVALLERE, called also in Italy Pietro Mulier or de Mulieribus. This artist, who is sometimes confounded with Antonio Tempesta, was a native of Holland, although better known in Italy, and his real name was Peter Molyn. Fiorillo says he was the son of a landscape-painter of the same name, and was born at Haar-

.em in 1637. He was called Tempesta through his skill in painting sea-storms and similar subjects, in which he was excellent, and in some respects rivalled Backhuyzen: he was also nearly equally excellent as an animal painter, especially of wild animals, and some have said that had he remained in his own country and pursued entirely such subjects, he would have rivalled Rubens and Snyders in that department. There is yet another comparison to make respecting him; he rivalled, or perhaps surpassed, the infamous Castagno in moral depravity. Pascoli, who has written an account of Tempesta in his 'Lives of the Painters,' &c., says that his father was a merchant, and that he intended to bring up his son to his own business; young Peter was however naturally so fond of drawing, that when a boy, instead of going to school, he used, unknown to his parents, to spend his time in sketching upon the sea-side, sometimes drawing the sea and shipping off the coast, and at others cattle grazing near the shore. He was eventually allowed to take his own course, but nature appears to have been his only or at least chief master. After painting with great success in various cities of the Netherlands, he became acquainted at Antwerp, in about his 30th year, with a monk of the barefooted Carmelites, who converted him from Calvinism, in which he had been brought up, to Popery; and Tempesta was thence strongly induced to make a journey to Rome. At Rome he found a valuable patron in the Duke Bracciano, and his success was beyond his expectations. He received so many orders for pictures, that he was obliged to employ assistants; and the sister of one of these, his favourite, known as Tempestino, became his wife. He however never appears to have lived in great amity with her, but the fault is said to have been Tempesta's. The story of the deep tragedy which followed is told differently by Pascoli, and the writer in the 'Museo Fiorentino,' in which there is a Life of Tempesta, but there is no discrepancy in their statements of the main fact. Tempesta made up his mind to leave Rome, it is said, in order to get rid of his wife, and he requested permission of the Duke Bracciano to depart: the duke consented, but unwillingly, yet he presented Tempesta with a cross and a chain of gold, and knighted him before his departure. Tempesta left Rome, and promised to send for his wife as soon as he was settled; he went round by Venice and Milan, where he made a short stay, to Genoa. In Genoa he was as successful as he had been at Rome; but soon after his arrival he became enamoured of a beautiful Genoese lady, and being unable to obtain possession of her except by marriage, he resolved upon marrying her, and he got over the obstacle of already having one wife in the following infamous manner:—He dispatched a hired assassin to Rome, with a letter to his wife, ordering her to accompany the bearer immediately to Genoa; his wife, who knew her husband's character, and disliked the messenger, delayed going, but on a second summons from her husband she complied, and commenced the fatal journey. The unfortunate woman was murdered by the ruffian, her companion, at Sarzana. The affair was not long a secret, and Tempesta, who must have already married the Genoese lady, according to Pascoli, was arrested upon suspicion, was tried, convicted, and condemned to death. The sentence was however not carried into execution: Tempesta obtained a respite, or, according to the other account, had sufficient interest to obtain a commutation of sentence from that of death to one of perpetual imprisonment.

Pascoli says he was set at liberty again, after remaining five years in prison, through the intercession of the Count di Melgar, governor of Milan; according to the other story, he obtained his liberty during the bombardment of Genoa by Louis XIV., when the prisons were thrown open; having suffered an imprisonment of sixteen years. He was however busily employed with his pencil during the whole time, and he found it difficult to satisfy the demand for his pictures. On recovering his liberty he went to Milan, and there established himself, where, through his unenviable notoriety, his success was even greater than it had been previously either at Rome or at Genoa. He was in the receipt of a great income, lived in splendid style, and even kept a private menagerie, containing many varieties of wild animals, solely for the purpose of painting from them. His conduct at this period of his life was still consistent with his previous immorality, for though enjoying the greatest affluence, he not only deserted his second wife, but left her destitute, according to Pascoli; yet how such conduct could be suffered by the laws is difficult to understand. He had several mistresses, and he acquired the cognomen of Mulier or de Mulieribus by his profligate habits; Peter Mulier is the name by which he is best known in Italy. As he grew old his powers of painting forsook him, and his means accordingly gradually diminished, and as he was too improvident to make any provision for his old age, his affairs became embarrassed at the end of his life. He died of a fever in 1701, aged 64, in a state of poverty when compared with his former affluence. His pictures are numerous in the collections of the north of Italy: those which he painted during his imprisonment are generally accounted his best.

. TEMPIO. [SARDEGNA.]

TEMPLARS, KNIGHTS TEMPLARS, or KNIGHTS OF THE TEMPLE, are the popular designations for the Brethren of the Temple of Solomon at Jerusalem, also called the Soldiery of the Temple (Militia Templi) and the Soldiers of Christ. The three great religious military Orders, the Knights of the Hospital of St. John of Jerusalem (commonly called the Knights Hospitallers), the Templars, and the Teutonic Knights of St. Mary of Jerusalem (or German Knights of the Cross), all originated in the twelfth century; the two former towards its commencement, during the first crusade, the last not till near its close. The founders of the Order of the Templars, which is held to date from the year 1118 or 1119, were nine Knights, all French, of whom the two chief were Hugues de Payens or de Paganès) and Geoffroi de St Omer (or St. Ademar). One account makes all the nine to have been previously members of the Order of St. John; but it is at least doubtful if this was the case. At all events, the Hospitallers were not yet a military order; their distinguishing profession was to entertain pilgrims and to attend the sick and wounded; the idea of adding to the three common vows of chastity, poverty, and obedience, an engagement to fight against the infidels, appears to have been first put in practice by De Payens and his brethren. Up to this time, when a knight entered the society of the Hospitallers, he seems to have laid aside his arms. Nor probably did the nine Knights forming the new association at first contemplate either the extensively military character which their order eventually assumed, or even the establishment of an order which should extend and perpetuate itself. Their original vow was simply to maintain free passage for the pilgrims who should visit the Holy Land; nor did they proceed to add to their number till six or seven years after their association. In another respect also their early condition and pretensions were remarkably contrasted with their subsequent state; for at this time they made the greatest show of poverty, even De Payens, who was styled Master, and his friend De St. Omer, keeping only one horse between them, a circumstance commemorated in the seal of the order, which represents two armed knights mounted one behind the other on the same horse. At this their beginning, indeed, the name which they took, and by which they were commonly known, was the Pauper soldiers (*Pauperes Commilitones*) of the Holy City; and they professed to have no source of subsistence but the alms of the faithful. The king of Jerusalem, Baldwin II., gave them their first place of residence, a part of his palace; to which the abbot and canons of the church and convent of the Temple, which stood adjoining, added another building for keeping their arms, whence they acquired the name of Templars.

The new principle of their association, however, immediately drew general attention; so much so, that in 1120 the Hospitallers got their order remodelled by Pope Calixtus II. on the same principle. The first regular embodying of the Templars was by Honorius II., the successor of Calixtus, who in 1128 confirmed a rule for them which had been drawn up and decreed that same year by the Council of Troyes, on the requisition of Hugues de Payens and several of his brethren, who had come to Europe for that purpose with strong recommendations from king Baldwin. Honorius at the same time, to distinguish them from the Hospitallers, who were arrayed in a black mantle, assigned the brethren of the new order a white mantle for their peculiar dress, which they wore plain till Eugenius III., in 1146, appointed them to wear a red cross on the left breast, in imitation of the white

cross worn by the Hospitallers. This bloody cross was also borne upon their banner, which was formed of cloth striped black and white; whence it was called *Bauseant*, an old French term applied to a horse marked with these colours. This word consequently became the famous warcry of the Templar chivalry.

The new order speedily rose into consideration. Members of the noblest families in every nation of Christendom eagerly sought to be joined to it; legacies and donations in lands and money were showered upon it by persons of all ranks; and in course of time it acquired ample possessions in nearly every country of Europe. At the head of the order was the Master, or Grand-master (*Magister*, or *Magnus Magister*), who was however not only elected by the Chapter, or general body of the Knights, but very much controlled by that body: the Grand-Master had immediately under him his Seneschal, or lieutenant; and other high officers were the Marshal, the Treasurer, &c. The several countries in Asia and Europe in which the order had possessions were denominated Provinces; and each of them was presided over by a resident chief, called, indifferently, a Grand Prior, Grand Preceptor, or Provincial Master. Under the provincial masters were the Priors, otherwise called Bailifs, or Masters, who had charge each of one of the districts into which the province was divided; and finally, under the priors were the Preceptors, each of whom presided over a single house of the order (or sometimes over two or three adjoining houses which were considered as one establishment), hence called a Preceptory. The head province was that of Jerusalem; the affairs of the order, in fact, were for the most part directed by the chapter of this province, which was invested by the constitution with all the powers of a general chapter at all times when such a chapter was not assembled. The grand-prior of Jerusalem was ex-officio treasurer of the order; and in this province the grand-master resided so long as the Christians retained any footing in the country: first in the city of Jerusalem, from the origin of the order till 1187, when Jerusalem was taken, and the kingdom founded by Godfrey of Bouillon put an end to, by Saladin; then (after a retirement of four years to Antioch) at Acre, from 1191 till 1217; then at the newly-built fortress of the Pilgrims' Castle, situated on the sea-coast a few miles north of Cæsarea, till the fall of Acre, and the final extinction of the Latin power in Palestine, in 1192. On this the Knights took refuge in the town of Limisso (otherwise called Limasol) in Cyprus. The other provinces in the east were Tripolis and Antioch; to which Cyprus, till then included in one of these, was added after that island became the head-quarters of the order. The western provinces were, Portugal, Castile and Leon, Aragon, France and Auvergne, Normandy, Aquitaine or Poitou, Provence, England (in which Scotland and Ireland were included), Germany, Upper and Central Italy, Apulia, and Sicily.

For some time after its institution the order of the Templars consisted exclusively of laymen. But in the year 1162, the famous bull entitled 'Omne Datum Optimum,' issued by Pope Alexander III., among other important privileges which it bestowed upon the order, permitted it to receive as members any spiritual persons who were not bound by previous vows. These spiritual members were called Chaplains. They did not fight, nor take the military vow; but, in lieu of that duty, they not only celebrated mass and other religious offices in the houses of the order, but usually also acted as secretaries to the chapter. They were not allowed to take any share in the government of the society unless specially invited by their superiors; but they were treated with much ceremonious respect, and they were frequently appointed preceptors. Among the other privileges granted by the bull of 1162, was that of having the offices of religion celebrated once in the year in the houses of the order, even in countries lying under an interdict; a permission well calculated to induce persons to join the society, especially after it came, as is asserted, to be interpreted in practice as entirely exempting the Templars from the effects of interdicts. Alexander's bull also allowed the order to have its own burial-grounds; released it from all spiritual obedience, except only to the holy see; freed it from the payment of tithes, and even authorised it to receive them if the bishop gave his consent; and prohibited any one who had once become a Templar from ever leaving the order unless to enter into a stricter one.

At a date a little later the society still farther extended its scheme and its influence, by admitting as members many persons who were not knights or of noble birth, but who were desirous of participating in the advantages of belonging to so powerful a body, on condition of acting as the squires and servants of the knights. These were styled Serving Brethren; and in this class were sometimes found individuals both of great wealth and eminent station, though not of high birth or knightly rank. The serving-brethren however could not be preceptors, or hold any of the higher offices in the order. Latterly, they were divided into two classes—those of arms and those of trades; the former attending the knights to the field as esquires; the latter exercising various handicrafts in the houses or on the lands belonging to the order. The serving-brethren of arms were considered to form by much the more honourable of the two classes, and were treated with much more consideration than the others; but both appear to have been equally entitled to be present at meetings of the chapter, although it may be presumed that none of the serving-brethren either voted or took part in the deliberations. The order also associated to itself many persons under the name of Affiliated Members, who took no vows, assumed no peculiar dress, nor became subject to any duties or services; but, continuing to pursue their ordinary secular occupations, merely purchased enrolment in the ranks of the powerful and highly privileged soldiery of the Temple for the sake of the protection and other advantages, both temporal and spiritual, which even such a mere nominal membership ensured. The affiliated comprehended women as well as men. Finally, there were the *Donati* and the *Oblati*, consisting of children dedicated to the order by their parents or other relations; and also of persons of all ranks, both laity and clergy, who, without entering the order, pledged themselves to stand by it and to maintain its rights.

The history of the Knights Templars would embrace the history of the wars of the Christians against the Infidels in the East for all the time they lasted after the establishment of the order. For more than a hundred and seventy years the soldiers of the Temple formed the most renowned portion of the Christian troops, and almost every encounter with the enemy bore testimony to their unequalled prowess and daring. But it may nevertheless be questioned whether the establishment of this and the other religious military orders proved advantageous to the attempt so perseveringly made to wrest the Holy Land from the dominion of the Infidels. The Templars and Hospitallers probably damaged and weakened the cause for which they fought, as much by their rivalry, jealousies, and frequently open contention, as they aided it by their valour. On some occasions this opposition between the two orders rose so high as not only to make them desert or withhold assistance from each other in the extremest dangers, but even to throw one of them for the time into concert with the common enemy. No charge (though such charges have been brought) can be substantiated against the bravery of either; but they can hardly be acquitted of treachery in some instances to one another, and the most scandalous abandonment of their duties to the public cause. Then, the immense wealth and worldly power which the Templars in particular speedily acquired altogether changed the original character and spirit of their institution long before it was half a century old. Within thirty or forty years from the origin of the order, two at least of the four vows which the members still continued to take had become a mockery and a profanation; instead of poverty and chastity, they were already distinguished by their pomp and pride, and the general luxury and licentiousness of their lives. But the vast material forces of the association, the extent to which it had projected its ramifications in all directions, and its other elements of strength, might have long withstood the principle of corruption thus at work within it, if it had not drawn upon itself an assault from without by which it could not fail to be overpowered.

The destroyer of the Templars was the resolute and vindictive Philip IV., surnamed Le Bel, or The Fair, of France. Philip, who came to the throne in 1285, at the age of seventeen, was the enemy of the church by education, by temper, and by circumstances. He had already proceeded to extremities in a quarrel with Pope Boniface VIII., which was terminated only with the life of that

pontiff. His successor, Benedict XI., is supposed to have been poisoned at the instigation of Philip. Benedict was succeeded by Clement V., who is believed to have purchased his elevation from Philip on condition, among other compliances, of co-operating with him in the destruction of the Templars. This was in 1305. Obnoxious already as the natural allies and defenders of the Holy See, and tempting the attack of the needy and unscrupulous king by their immense possessions, these knights are also said to have further irritated Philip about this time by their suspected share in exciting an insurrection of the Parisians against a debasement of the coinage, a practice which he repeated so often in the course of his reign, that he acquired for himself the name of the money-forger (le faux-monnoyeur).

In 1306 Jacques de Molay, the master of the Temple, was drawn to Europe by a summons from the pope, who professed a desire to consult with him on the expediency of a union of the two orders of the Templars and the Hospitallers. The following year, while Molay was at Paris, the first distinct accusations against the Templars were made by two individuals lying in prison under sentence of death; Squin de Flexian, who had formerly been a member of the order and prior of Montfaucon, but had been ejected for heresy and other offences, and a Florentine called Noffo Dei, also, according to one account, a degraded Templar, by general admission a person of the worst character. They made their revelations to Philip himself, and were immediately liberated from prison. Their charges, imputing to the order the systematic practice and encouragement of all sorts of secret immoralities, as well as the strangest confusion of heresy, idolatry, and infidelity, are far too absurd for examination. Very soon after this, on the 12th of September, 1307, royal letters were issued sealed to all the governors of towns and other officers of the crown in authority throughout the kingdom, and transmitted along with orders to them to arm themselves and the persons under their command on that day month, and then to open the letters in the night, and to act as they should find themselves therein directed. The result was that the next day nearly all the Templars in France, De Molay included, were in custody. Their houses and goods were also everywhere seized; the vast stronghold of the Temple at Paris, the chief seat of the order in that kingdom, was entered and taken possession of by Philip himself; and on the following day, the 15th, the university met there, and examined De Molay and some other knights.

An act of accusation was forthwith published; and Philip at the same time wrote to the pope, and also to the king of England, intimating what he had done, and calling upon them to second him. Edward II. expressed himself at first disinclined to believe what was said against the knights; but on soon after receiving letters from Clement, he yielded, and the English Templars were also all seized and thrown into confinement about the end of December. Meanwhile the examinations had been going on in France under the direction of the king's confessor, Imbert, a Dominican priest, and as such the inveterate enemy of the order of the Templars. Confessions, in many cases incredible from their inherent absurdity, were extracted from many of the knights at Paris and elsewhere by the most savage tortures: the confession was in numerous instances speedily followed by a recantation; but a new application of the wheel, or the fire, to which the accused were exposed in some cases till the roasted flesh dropped from the soles of their feet, generally made them repeat their former testimony. This went on for many months. In August, 1308, Clement, whose very person Philip had now contrived to get completely into his power, issued a bull, calling upon all Christian princes and prelates to aid him in examining into the guilt of the order; and about the same time his holiness appointed a commission, consisting of the archbishop of Narbonne and other prelates and dignitaries of the church, to meet at Paris to try the case. This commission however did not commence its sittings till the 7th of August, 1309. A few months later, examinations under judges, deputed or nominated by the pope, commenced in England and other countries. Altogether many hundreds of knights were examined by these commissions during the years 1309, 1310, and 1311; but it was only in France, where torture was made use of, that any admissions were obtained of the crimes laid to the charge of the order, or any at least that were not manifestly and undeniably unworthy of all regard. Even the Paris commission however did not satisfy the impatience of Philip: on its requisition a great number of knights had stood forward to defend the order, among whom were several of those who had confessed and afterwards retracted. Philip, having forced the pope to nominate Philip de Marigni, bishop of Cambray, the brother of Enguerrand de Marigni, his prime-minister, to the archbishopric of Sens, which had just become vacant, and then included the diocese of Paris, got the new archbishop to convoke his provincial council in the capital, on Sunday, the 10th of May, 1310; and this body, on the Wednesday morning following, had fifty-four of the defenders of the order, who had formerly made confession, brought out as 'relapsed heretics' to a field behind the abbey of St. Antoine, and there committed to the flames. They all died asserting their innocence and that of the order. This terrible example was speedily imitated in the province of Rheims and elsewhere; and some months after, the archbishop of Sens held himself another council, and burned four more knights. These proceedings put a stop to the attempt at defending the order: the rest of the knights who had undertaken this task now all declared their renouncement of it. Meanwhile a general council had been appointed by Clement to meet at Vienne in October, 1311. It assembled on the 13th of that month, but it was not found so compliant as Philip and the pope had expected; and Clement, having put an end to the session, assembled the cardinals and a few other prelates upon whom he could depend in a secret consistory, and abolished the order by his own authority, on the 22nd of March, 1312. When the council reassembled, pursuant to the adjournment, on the 3rd of April, Philip was seated on Clement's right hand, accompanied by his brother and his sons, and attended by an imposing military force; and his holiness read the bull of abolition, the council listening in silence. It was formally published on the 2nd of May following. On the 18th of March, 1314, Molay, the grand-master, and Guy, commander or grand-prior of Normandy, who had all this while remained in prison at Paris, were brought before the archbishop of Sens, condemned to death, and burned on one of the small islands in the Seine, about the spot where the statue of Henri IV. is now erected on the Pont Neuf.

After all, Clement and Philip, the former of whom died suddenly about a month, and the latter, of a fall from his horse, within a year after the martyrdom of De Molay, were able to secure to themselves only a small portion of the plunder which they had probably hoped for. The king of France seized and kept, or divided with his confederate, the moveable property of the Templars in that country; but there, and also in England, and throughout the rest of Europe, with the exception of Spain and Portugal, it was found necessary to transfer their landed possessions to the Hospitallers, or Knights of St. John (at this time commonly known, from the place where they had fixed their head residence, as the Knights of Rhodes). In Spain the lands of the Templars were bestowed upon the Knights of Our Lady of Montesa, a new order, founded in 1317; and in Portugal the society merely took the new name of the Order of Christ, which still subsists. It is affirmed that even in France the order of the Templars has survived to our own day; and it is certain that a society calling itself by that name exists in Paris, which professes to be in possession of the original register and records of the antient Templars, and to have been governed by an unbroken succession of grand-masters, many of them of illustrious rank, ever since the time of Jacques de Molay. It pretends therefore to be the supreme chapter of the order. In England, and we believe also in Germany, the Freemasons are in the habit of holding themselves up as a sort of representatives of the antient Templars.

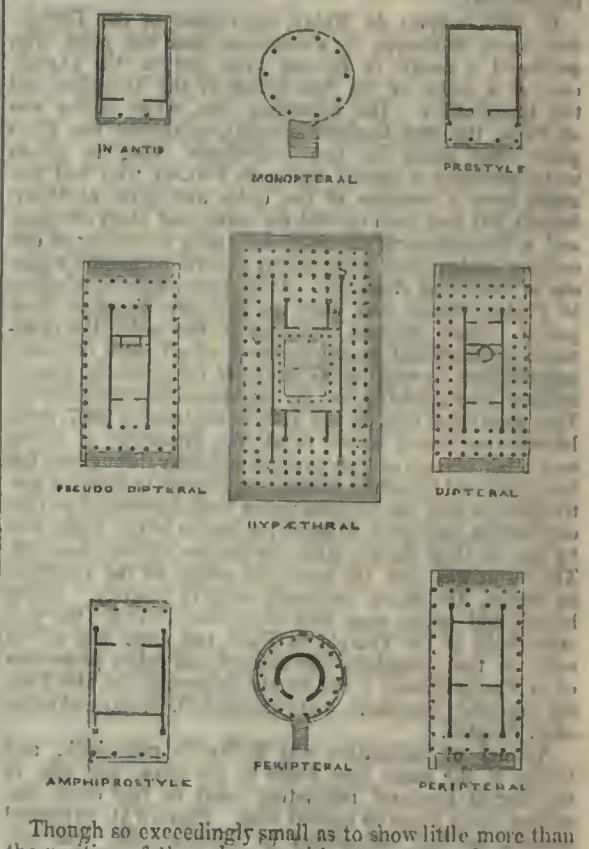
It is asserted by Matthew Paris, that about the year 1244 the manors or estates in possession of the Templars throughout Christendom already amounted to 9000; and it has been calculated that the entire revenues of the order when it was dissolved did not fall short of six millions sterling, though it seems impossible that this should not be a great exaggeration. Their possessions in England particularly were even at a comparatively early period of great extent and value, as may be seen from an 'inquisitio,' or account

of their lands, taken by royal authority in the year 1185, which Dugdale has printed in his 'Monasticon' (vol. vi., pt. ii., pp. 815, &c., edition of 1830). They are supposed to have been settled in the Old Temple, at London, which stood on the south side of Holborn, near the present Southampton Buildings, by the beginning of the reign of Stephen: they removed to their new house at the western extremity of Fleet Street, the site of which still retains the name of the Temple, in 1185. This was the chief seat of the order in England.

The question of the guilt or innocence of the Templars has been much discussed in modern times; and although it may be said to be now almost universally admitted that the particular charges upon which they were condemned were for the most part entirely unfounded, some attempts have been made to show the probability that the order nevertheless was held together by certain secret principles or doctrines which made its existence dangerous to society and called for its suppression. Von Hammer, for instance, in his 'Geschichte der Assassinen' (or 'History of the Assassins'), of which there is an English translation by Dr. G. C. Wood, has endeavoured to establish a similarity and connection between the order of the Templars and that famous association; and in a disquisition, printed in the sixth volume of his 'Mines de l'Orient,' the same writer has attempted to convict the order of a participation in the apostasy, idolatry, and impiety of the Gnostics and Ophianites. Von Hammer's Essay has been answered by M. Raynouard, in a long note printed in the fifth volume of Michaud's 'Histoire des Croisades,' p. 572, &c.; and also in two articles in the 'Journal des Savans' for March and April, 1819; and in two others, published in the 'Bibliothèque Universelle,' tom. x., p. 327, and tom. x., p. 3. The documents relating to the condemnation of the Templars were first published in a work entitled 'Traitez concernant la Condemnation des Templiers,' par M. Du Puy, 8vo., Paris, 1654; reprinted, with additions, under the title of 'Histoire de la Condemnation des Templiers,' &c., par Pierre Du Puy, 2 vols. 8vo., Bruxelles, 1713; and under that of 'Histoire de l'Ordre Militaire des Templiers, avec les Pièces Justificatives,' 4to., Bruxelles, 1751. Other works on the subject are —'Nicolai Gürtleri Historia Templariorum,' 8vo., Amstel., 1691, and, with large additions, 1703; 'Christiani Thomasii Dissertatio de Templariorum Equitum Ordine Sublato,' 4to., Halae, 1705; Ravnouard, 'Monumens Historiques relatifs à la Condamnation des Templiers,' 8vo., Paris, 1813; Voltaire, 'Essai sur les Mœurs et l'Esprit des Nations,' chap. 66; Munter, 'Statutenbuch des Ordens der Tempelherren;' Wilike, 'Geschichte des Tempelherrenordens;' 'Secret Societies of the Middle Ages' (in the 'Library of Entertaining Knowledge'), 12mo., Lond., 1837; and 'The History of the Knights Templars, the Temple Church, and the Temple,' by C. G. Addison, Esq., 4to., Lond., 1842. See also Tanner's 'Notitia Monastica,' fol., Lond., 1744, pp. 307-310, for numerous references to printed books and MSS. on the subject of the English Templars.

TEMPLE (the Latin 'Templum'). What is known of the architecture of the nations of antiquity is derived chiefly from their temples; for of all their public edifices those devoted to religion are the most numerous, if we except perhaps those of the Romans, the remains of whose thermæ, aqueducts, theatres, amphitheatres, and other monuments of that class, are as common as their temples, and have been as well preserved. Nearly all of what may, for distinction's sake, be termed the *columnar* architecture of the nations—Egyptians, Greeks, and Romans—is seen in their temples. In those of the Egyptians, it may be said to display itself exclusively, and likewise much more extensively than in the temples of the other two, with this further difference as regards the general design and character, viz. that in the Egyptian edifices the columns are placed *internally*, that is, so as to form colonnades along the sides of an enclosed fore-court, and the portal or frontispiece of the temple itself. Of this disposition of the entire plan, with a walled-in cortile or cloister, an example is shown in Egyptian Architecture (p. 316), where other particulars relative to Egyptian temples and some of the characteristic differences between them and those of the Greeks are mentioned. Instead of being composed of a variety of parts grouped and combined together, these latter consist only of a simple parallelogram, a *cella*, or body of the temple itself, either *in antis*, or else *peripteral*, that is, entirely surrounded with an external colonnade; for to these two distinctions may be reduced all those subordinate ones for which separate technical terms have been invented, yet they do not at all affect the general shape and outline, which still remains a simple unbroken parallelogram, either with or without external colonnades along its sides.

An explanation of those terms having been given in Civil Architecture, page 221, col. 1, we refer to what is there said for the respective definitions, and instead of repeating them, now introduce here what will render them more intelligible, and be of assistance in the present article, viz. examples of the different forms of plan as regards *columniation*, or the arrangement of the columns.



Though so exceedingly small as to show little more than the position of the columns, without any regard to exactness in other respects, these slight diagrams will both serve to render evident many circumstances that cannot else be fully explained, and also to exemplify the respective denominations of temples and porticos according to the number of columns in front. The one 'in antis' is a *distyle in antis*, there being only two columns between the antæ, or three intercolumns, as in the two tetrastyle examples (prostyle and amphiprostyle); whereas were there four columns between the antæ, it would become *tetrastyle in antis*, and have as many intercolumns as an *hexastyle*, of which last the peripteral figure is an example. The dipteral and pseudo-dipteral are both *octastyles;* and the hypæthral a *decastyle*. This last may also be taken as an example (though an imperfect one) of a *diprostyle*, for it will be seen that if the portico were a mere prostyle, it would project forward two intercolumns from the body of the temple. In this figure the pronaos may also be termed *polystyle*, on account of the great number of columns in successive rows between the side walls enclosing that part of the plan (pronaos), which may be described as a dipteral or double *tetrastyle in antis*, having a distyle in antis behind it, and a *diprostyle decastyle* in front of it.*

Still there is no variety whatever as to external form, no individual character as to outline or even the general pro-

* Though such is the case in the plan given above as an example of an hypæthral, it must not therefore be supposed either that all decastyle temples were hypæthral, or all hypæthral ones decastyle; neither, again, that all dipteral ones had deep polystyle pronaoi filled with files of columns continued on the lines of those in front.

portions, nothing of combination or of design, as the last term is usually understood; but the difference of effect depended altogether upon the actual dimensions of the structures, upon material and execution, upon circumstances of detail and finish, and on the degree and particular kind of decoration in regard to sculpture and polychromic embellishment. The only instance of combination and grouping is that afforded by the Erechtheion, or triple temple on the Acropolis at Athens, which has two distinct porticos, viz. an Ionic hexastyle monoprostyle at its east end, and a tetrastyle diprostyle of the same order on its north side, and upon a lower level; besides which there is a smaller attached or projecting structure at the south-west angle, forming a tetrastyle diprostyle arrangement of caryatic figures, raised upon a screen-wall or podium. The combination is here not very harmonious, since no regard has been paid to symmetry; for which very reason it is all the more striking, as forming a decided contrast to the unvaried and even monotonous uniformity pervading the temple-architecture of the Greeks. It is almost the only Grecian structure that can be said to be as much distinguished by picturesqueness as by elegance of architectural detail, and it is therefore to be regretted that it has not been studied by modern architects, with especial reference to such quality, instead of their attention being almost exclusively given to the details and proportions of the individual parts. This edifice moreover affords almost the only instance in the Grecian style of distinct porticos or prostyles projecting from a building [Portico], other porticos being either in *antis*, so as to be *recessed* within the main walls forming the sides of the edifice; or are only the end or ends of the colonnades continued throughout the whole exterior: consequently in neither case does such portico show itself as an actual prostyle. The only other known examples of Greek prostyles are the two small Ionic temples at Athens, that on the banks of the Ilissus, called the temple of Panops; and that dedicated to Nike Apteros, or Wingless Victory. Both these were amphiprostyle, and not *in antis*, consequently had a projecting portico at each end; and in both the porticos were tetrastyle. Of the former nothing now remains, but it is well known from Stuart's delineations, and the order itself—of plain and bold but elegant character—has been adopted as the type—not to say stereotype—of most of our modern Grecian Ionic. Though amphiprostyle, the porticos were not exactly similar in plan; for while the one was a mere monoprostyle, that forming the entrance end was also deeply recessed within the main walls, after the manner of a portico in antis without columns. The other temple, the ruins of which have been explored within only a very few years, was a very small structure, a mere votive chapel, close by the west front of the Propylæa of the Acropolis, with its hinder portico facing the south wing of that edifice, yet turned obliquely from it, which want of parallelism is utterly at variance with all modern notions of architectural symmetry and order. Yet although they carried regularity almost to faulty excess, the Greeks seem to have paid no regard to it whatever in disposing buildings relatively to each other, for there is a similar and apparently intentional want of parallelism between the Parthenon and Erechtheion on the Acropolis itself; nor are either of them in a line with the Propylæa, or equidistant from such line or axis. [Parthenon—Plan.]

This inattention to uniformity of arrangement, where different buildings are brought together on one general plan, shows a striking difference of taste in that respect between the Egyptians and the Greeks. The temples of the Egyptians consist of various architectural parts subordinate to the principal structure, but combining with that and with each other to form a whole; which scheme was sometimes further extended by an architectural avenue of sphinxes in front of the buildings. The Greeks, on the contrary, certainly did not attempt to imitate or rival the Egyptians in the extent and complex arrangement of their temples, though there can be little doubt that they were originally indebted to them for much of their architectural knowledge. Their temples were almost invariably single structures, not only detached from but altogether unconnected with adjacent ones, instead of forming with them a symmetrically arranged assemblage or group. It seems however to have been in some degree the practice to erect several temples in the immediate neighbourhood of each other, and in a particular district of a city, as was the case in the Forum and Capitol at Rome, where temple succeeded to temple almost uninterruptedly; and the ruins of Pæstum, Agrigentum, Selinus, and other places show a somewhat similar concentration of sacred edifices about the same spot. Temples were frequently surrounded by a sacred grove or plantation of trees, *Temenos*, or else placed within an enclosure, *Peribolus*, formed either by mere walls or by colonnades, but there are scarcely any examples of the kind now remaining; and they are chiefly Roman works, viz. the temples at Baalbec and Palmyra. Similarly enclosed and standing in the centre of a peribolus or piazza (therefore very different in plan from an Egyptian temple preceded by a fore-court), were the temples of Jupiter and Juno, Venus and Roma, at Rome [Roman Architecture, p. 74]; that of Jupiter Olympius at Athens, a work completed in the time of Hadrian; and also, among Græco-Asiatic examples, the temples of Minerva Polias at Priene, and Apollo Didymæus at Miletus.

Similar as it is upon the whole to that of the Greeks, the temple-architecture of the Romans differs from it in many other circumstances besides those of style; which latter was, with very few exceptions, Corinthian—the national style of the Romans, as the Doric was of Greece and its Italian colonies. One leading distinction in regard to general arrangement is, that Roman plans were hardly ever *in antis*, and not often *peripteral*, but generally prostyle, with the portico projecting out from the *cella*, or body of the structure, three or more intercolumns, so as to be *triprostyle*, &c. [Portico.] Such façade was generally further distinguished by having a flight of steps enclosed within pedestals at its ends, which were continued as a podium or moulded basement along the sides of the edifice; whereas the Greeks raised the temples only three steps or so above the ground, and carried those gradini quite round the structure, wherefore each elevation or side of their peripteral temples was uniform in design, having no other variety than that produced by greater extent and number of columns in one direction, and by the pediments at the extremities. The Romans certainly evinced greater taste for both contrast and picturesque combination than the Greeks, although decidedly inferior to them in beauty of detail and finish of execution; except perhaps in one or two particular examples of that order which, although called Corinthian, is so peculiarly their own, that Roman would be the more correct name for it. In order to give greater dignity to the whole temple or to the principal structure in an architectural group, they elevated it upon not a mere basement or substructure with an ascent in front or at both ends, but upon a spreading-out platform, constituting a terrace on every side. They appear to have occasionally formed a succession of terraces of flights of steps, leading up to if not continued on every side of the building. The celebrated Temple of Fortune at Præneste, usually supposed to have been originally founded by Sulla, was a very remarkable example of the kind. Very little now remains of it, except the terraces themselves; neither have we any account of the architecture, but besides the principal edifice or temple there were several subordinate ones, on the different platforms. 'I know of no other example,' says Woods, in his 'Letters of an Architect,' 'either of antient or modern times, where so great a number of edifices, and occupying so great an extent, were combined into one regular and symmetrical plan; and our admiration is still increased when we consider that it was necessary not only to erect the building, but absolutely to build a place for it to stand on.'

Circular plans for temples are peculiar to the Romans, and occasion a diversity of character not to be met with in those of the Greeks. Besides the two simplest forms, the monopteral and peripteral, which have been shown above, there were other varieties and combinations. For a notice of some of them we refer to Roman Architecture (p. 73).

Instead of entering into formal descriptions of particular temples, we subjoin a synopsis with accompanying remarks. Some of the measurements and other particulars stated in it may not exactly accord with other accounts of the respective structures; for so great is frequently the discrepancy between different authorities, whether writers or delineators and restorers, that it is impossible to obtain complete accuracy.

TABLE OF SOME OF THE PRINCIPAL GREEK AND ROMAN TEMPLES.

Athens	Theseion	Doric	Hexastyle, peripteral, with 12 intercolumns on sides, 46 × 105 feet.
,,	Parthenon	Doric	Octastyle, peripteral, hypæthral, 100×228 feet; Ictinus and Callicrates, architects. [PARTHENON.]
,,	Propylæa	Doric	Hexastyle on both fronts, with wings of a smaller order, at right angles to west front. [PARTHENON—Plan.] Mnesicles, architect, 437–432 B.C.
,,	Erechtheion	Ionic	Hexastyle, prostyle at east end, with a tetrastyle, diprostyle on north side.
,,	Panops	Ionic	Tetrastyle, amphiprostyle. A well-known example, though no longer extant, having been destroyed by the Turks since Stuart's time.
,,	Nike Apteros	Ionic	Tetrastyle, amphiprostyle. Recently explored, and since rebuilt.
,,	Jupiter Olympius	Corinthian	Decastyle, peripteral, columns 60 feet high, 96×259 feet. Enclosed by a peribolus. A Roman work originally begun in the time of Pisistratus, continued by Antiochus Epiphanes, and completed by Hadrian.
Eleusis	Ceres	Doric	A square building of about 180 feet on each side, with a dodecastyle colonnade forming the west front. This temple begun by Ictinus; colonnade added by Philo, architect, about 315 B.C.
,,	Propylæum	Doric	Hexastyle on both fronts, with inner Ionic order as at Athens, 50 × 60 feet. A second and smaller propylæa within the peribolus, distyle in antis. See 'Unedited Antiquities of Attica.' None of these buildings now remain.
Thorieus	. . . .	Doric	Eptastyle, peripteral, or with seven columns at each end, and fourteen on each side. No cella remaining; but supposed to have been a double temple, with a passage through the centre, from the sides, dividing the cella into two.
Rhamnus	Nemesis	Doric	Hexastyle, peripteral, 11 intercolumns on sides, 33×70 feet.
,,	Themis, or lesser Temp. of Nemesis	Doric	Distyle in antis.
Ægina	Jupiter Panhellenius	Doric	Hexastyle, peripteral, hypæthral, 41 × 90 feet. This structure is celebrated for its polychromy and sculpture (the Æginetan Marbles).
Olympia	Jupiter Olympius	Doric	Hexastyle, peripteral, hypæthral, 95 × 230 feet. Completed about 435 B.C. Libon, architect.
Bassæ	Apollo Epicurius	Doric	Hexastyle, peripteral, hypæthral, 47×125 feet. Date about 430 B.C. Ictinus, architect. In interior, Ionic columns.
Tegea	Athene Alea	Ionic	Peripteral, hypæthral. Doric internally; with upper Corinthian order. Scopas, architect.
Nemea	Jupiter	Doric	Hexastyle, peripteral.

MAGNA-GRÆCIA AND SICILY.

Pæstum	Neptune	Doric	Hexastyle, peripteral, hypæthral, 79×195 feet.
	Ceres	Doric	Hexastyle, peripteral, 47×107 feet. [PÆSTAN ARCHITECTURE.]
Agrigentum	Jupiter Olympius	Doric	Apteral, or with engaged columns, eptastyle, 182×369 feet. (For description, see AGRIGENTUM.) Wilkins, in his restoration of it, makes this temple hexastyle amphiprostyle.
,,	Juno Lucina	Doric	Hexastyle, peripteral, 57×124 feet.
,,	Concord	Doric	Hexastyle peripteral, 31×93 feet. Deep pronaos and opisthodomus.
Segeste	,,	Doric	Hexastyle, peripteral, 76×190 feet. All the external columns (unfluted) standing, but no remains of cella.
Selinus	Great Temple	Doric	Octastyle, dipteral, 160 × 330 feet. There are remains of five other temples, two of which appear to have been hexastyle peripteral.
Syracuse	Minerva	Doric	Hexastyle, 13 intercolumns on sides: now converted into a church with a modern Italian Corinthian façade.

ASIATIC GREEK.

Ephesus	Diana	Ionic	Decastyle, dipteral, hypæthral; columns 60 feet high; one of the largest Grecian temples, being 220 × 425 feet. Ctesiphon and Metagenes, architects. Date about 340 B.C.
Miletus	Apollo Didymæus	Ionic	Decastyle, dipteral, hypæthral, 164 × 303 feet. Columns 9½ diameters. Pæonius, architect. A peribolus.
Magnesia	Diana	Ionic	Octastyle, pseudo-dipteral, 106 × 198 feet. Hermogenes, architect.
Priene	Minerva Polias	Ionic	Hexastyle, peripteral, 64 × 116 feet. Pytheas, architect, about 340 B.C. The order the best example of Asiatic Ionic. This temple had a peribolus and propylæum; the latter tetrastyle, with two rows of square pillars within.

ASIATIC GREEK.

Teos	Bacchus	Ionic	Hexastyle, peripteral. Hermogenes, architect; about the time of Alexander the Great.
Samos	Juno	Ionic	Decastyle, dipteral; 189 × 346 feet.

ROMAN.

Rome	Concord	Ionic	Hexastyle. Appears to have been a diprostyle, but nothing of the cella remains.
,,	Furtuna Virilis	Ionic	Tetrastyle, diprostyle, cella pseudo-peripteral; about 24 × 44 feet.
,,	Jupiter and Juno	Corinthian	Two separate temples, alongside each other, in centre of a colonnaded peribolus. Similar in dimensions, but the one octastyle, peripteral; the other octastyle, diprostyle. Erected by Metellus Macedonicus, about 140 B.C. No remains; but the authority is the antient plan of Rome in the capitol.
,,	Jupiter Stator	Corinthian	Supposed to have been octastyle, peripteral. The celebrated 'Three Columns,' in the Forum, are all that now remain of this very fine example.
,,	Jupiter Tonans	Corinthian	Octastyle, dipteral; 92 × 115 feet. Columns 47 feet high.
,,	Mars Ultor	Corinthian	Of this temple, sometimes called that of Nerva, only three columns remaining; but it is said to have been octastyle, peripteral.
,,	Venus and Roma	Corinthian	Decastyle, pseudo-peripteral, enclosed within a peribolus formed by double colonnades of a lesser order. [ROMAN ARCHITECTURE, p. 74.]
,,	Antoninus and Faustina	Corinthian	Hexastyle, triprostyle; 33 × 55 feet.
,,	Pantheun	Corinthian	An octastyle, triprostyle, attached to a rotunda. [PANTHEON.]
,,	Vesta	Corinthian	A circular peripteral of 20 columns. [For further description, and an account of other temples at Rome, see ROME, p. 93, &c.]
Tivoli	Vesta, or the Sibyl	Corinthian	A circular peripteral, of 18 columns around cella. The order a very peculiar and fine example. [ROMAN ARCHITECTURE.]
Præneste	Fortuna		No remains of this celebrated temple itself; but merely of the series of terraces and flights of steps on which it was elevated.
Pompeii	Jupiter	Corinthian	Hexastyle, tetraprostyle; about 50 × 110 feet.
Nismes	Maison Carrée, or Temple of Caius and Lucius	Corinthian	Hexastyle, triprostyle; order continued along the cella, making it a pseudo-peripteral; 38 × 77 feet. [NISMES.]
Baalbec	Great Temple	Corinthian	Decastyle, peripteral; 160 × 290 feet. [BAALBEC.]
,,	Lesser Temple	Corinthian	Octastyle, peripteral; 118 × 225 feet. [BAALBEC.]
Palmyra	Helios, or the Sun	Corinthian	Octastyle, peripteral; 95 × 180 feet. Enclosed within a peribolus about 740 feet square, formed by an outer wall and two ranges of Corinthian columns, making a double colonnade. [PALMYRA.]

The above table might be rendered more copious and greatly extended; and it might also have been differently arranged in several ways, each of which would have had something to recommend it, according to the purpose for which it may happen to be consulted. Chronological order, for instance, if the respective dates could be ascertained with tolerable accuracy, may be considered preferable by some persons; or the buildings might have been classified according to the number of columns in front, and as being *in antis*, *prostyle*, *peripteral*, &c.; or else according to their relative size and dimensions. In fact a separate table is required for each mode of classification and arrangement; but as that could not be done, we have adopted what we consider the most satisfactory upon the whole. We may however render it in some measure more complete by here pointing out that the *decastyle* examples mentioned in it are the Temple of Jupiter, Athens; Diana, Ephesus; Apollo, Miletus; Juno, Samos; Venus and Roma, Rome; and the great temple at BAALBEC. As regards dimensions and relative size, the following are the largest structures, viz.:—

	Width of Front.	Length.
Ephesus . . .	220 feet	425 feet.
Agrigentum, Great Temple	182 ,,	369 ,,
Selinus, Great Temple .	160 ,,	330 ,,
Venus and Roma .	116 ,,	350 ,,
Athens, Parthenon .	100 ,,	228 ,,
Temple of Jupiter . .	96 ,,	259 ,,

By way of affording a standard of comparison, we add the dimensions of St. Paul's, London, and La Madeleine, at Paris, viz.: the former, 180 by 500; the other 138 by 328 feet.

TEMPLE, SOLOMON'S. For 447 years after the Hebrews had entered the land of Canaan they continued to worship at the tabernacle which had been framed for their use in the Wilderness. The incongruity of a settled people having only a tent for the celebration of their splendid ritual service first occurred to the mind of David. It appeared unseemly to him that the Ark of God should still 'dwell between curtains,' while he abode himself in 'a house of cedar,' and he therefore proposed to build a temple in which the worship of God might be more becomingly conducted (1 *Chron.*, xvii. 1). The prophet Nathan was however commissioned to inform him that having been engaged in constant warfare, and shed much human blood, he could not be allowed to execute the design he had formed, which was to be reserved for the peaceful reign of his son Solomon. This undertaking was however a principal subject of David's thought and care during the remainder of his reign; and to it he appropriated a large proportion of the immense treasure which his many victories produced. He may be said to have provided all, or nearly all, the materials before his death; consisting of large but variously estimated quantities of gold and silver, brass and iron, stone and timber. He also secured the services of skilful mechanics and artificers for every branch of the work, and furnished the design, plan, and site of the building; so that more of the credit of this work seems due to David than to Solomon (1 *Chron.*, xxi.; xxii.; xxviii. 11-19).

The foundation of the Temple was laid in B.C. 1012, being the fourth year of Solomon's reign; and in seven years and a half it was completed. During this time 183,000 persons were employed on the work. Of Jews there were 30,000 serving by rotation of 10,000 monthly; and of Canaanites there were 153,600, of whom 70,000 were labourers, 80,000 hewers of wood and stone, and

3600 overseers of the others. To save the labour of carriage, the parts were all prepared for use at a distance from the site of the building, and when they were brought together, the structure was reared without the sound of hammers, axes, or tools of iron (1 *Kings*, vi. 7).

To furnish a distinct idea of Solomon's temple from the materials which have reached us, even if we take in the ideal temple of Ezekiel, which is conceived to be framed on the same model, would require such a combination of real architectural knowledge with deep Biblical learning as have perhaps never been combined in any one person. Hence all the descriptions which have been deduced from such materials differ greatly from one another. These only claim our confidence in the points in which all, or nearly all, of them agree; for such points of agreement appear to embody all the real information which has hitherto been collected from the text. There are however materials of comparison and illustration, which, taken along with the text, might furnish some clearer notions than have yet been realized in a matter which circumstances have invested with considerable interest. 1. It would be considered that the temple was on the same essential plan as the tabernacle, differing chiefly in materials, extent, and in additions to the enclosure. 2. Reference would be made to other antient Oriental temples, of which we know more, and especially to those of Egypt, some of which are in sufficient preservation to allow their relative parts and proportions to be clearly understood. And in this regard it will be seen that those plans of the temple which appear most in agreement with the text offer the most striking analogies to Egyptian temples (see the chapter 'An Egyptian Temple,' vol. i., pp. 69-127, of 'Egyptian Antiquities,' in *Library of Entertaining Knowledge*). And although it is probable that, from the friendly relations which Solomon had already established with Egypt, Egyptian as well as Phœnician artists supplied the artistic labour for the temple in which the Hebrews were themselves deficient, such analogies need not be necessarily traced to imitation, but to similar conditions and circumstances producing similar results. The popular notion of a temple, as a vast pile of building in which, as in our cathedrals, large multitudes might assemble for worship under cover, does not in these cases apply. A temple was a large area, enclosed by a wall, and laid out in courts, where the crowds worshipped and where sacrifices were offered; and in colonnades around these courts, where the worshippers might walk or find shelter from the sun or rain. Apartments for the numerous officiating priests, and chambers for stores and treasures, also increased the display of building within and around the enclosing walls. The sacred edifice itself, being only intended to contain the sacred symbols, and being entered only by the priests for particular services, was never large; but what it wanted in size was made up in cost of materials and splendour of workmanship. These ideas apply equally to the temples of Jerusalem and of Egypt; and in both the sacred building was divided into three parts, which were in Solomon's temple called the Porch, the Holy Place, and the Most Holy Place, answering in some degree to the porch, the nave, and the chancel of Christian churches, the parts of which were indeed arranged originally with an intended reference to those of the Jewish temple. Even the pillars called Jachin and Boaz, which Solomon set up at the porch, find analogies in the obelisks which the Egyptians placed in a corresponding situation. 3. Another source of illustration is offered in the more ample description which is given by Josephus of Herod's temple; for although that appears to have been architecturally a greater and more imposing fabric than that of Solomon, there is no doubt that it had the same parts, and that they were similarly proportioned to each other. 4. The antient Christian churches also offer some analogies of arrangement, which claim to be considered when viewed as intended retrospects of the Jewish temple. Among the plans of antient churches given in Coleman (*Antiq. of the Christian Church*, Andover, U. S., 1841), that of the church at Tyre affords some remarkable illustrations.

The site of Solomon's Temple was the summit of Mount Moriah, one of the eminences on which Jerusalem stood. This eminence rose to no great height within the city, but was high and steep above the valley of the Kedron, which it overlooked. It faced the Mount of Olives. The Mosque of Omar now occupies the same site; and the imposing figure which it makes in every view of Jerusalem shows that a more advantageous situation could not have been chosen. The top of the hill was levelled, and the sides banked up to afford a sufficient area. This area was divided into two (but in Herod's temple three) courts, in the outermost of which stood the people. It was separated by a low wall (or, as some think, by a latticed fence or trellis) from the inner court, called the Court of the Priests, in which was the great altar of burnt offerings, and where the priests and Levites officiated in view of the people, and in front of the holy house, or proper temple. The proper temple, as previously indicated, was an oblong building. It was 70 cubits in length, 20 in width, and 30 in height: this last was however only the elevation of the house or holy place, for the innermost sanctuary was but 20 cubits high (1 *Kings*, vi. 20); and although the porch is said, in 1 *Chron.*, iii. 4, to have been 120 cubits high, or four times the height of the main building, the numbers in that text are now generally admitted to be corrupted: 20 cubits, which we find in the antient versions, is probably the true number; being the same height as the sanctuary. The porch covered the breadth of the building 20 cubits, and was 10 cubits deep: the holy place was 40 cubits long by 20 wide; and the sanctuary was a perfect square of 20 cubits. The building fronted the east. Along the north and south sides, and the west end of the structure, were attached certain buildings called 'side chambers,' in three stories, each five cubits high. This made 15 cubits of total elevation, which was not more than half the height of the main building, in whose walls, above, there was therefore room for the splayed windows which gave light to the temple.

The sacred utensils were of the same description and occupied the same relative position as in the tabernacle: but some of them were larger, as the altar, candlestick, &c., in proportion to the more extensive establishment to which they belonged. The principal of the new utensils was the great brazen laver for ablutions, which rested on the backs of twelve oxen of the same metal.

The inner sanctuary was separated from the holy place by a rich curtain or veil. The whole of the interior was wainscoted with cedar, carved with figures of cherubim, palm-trees, and flowers, and then overlaid with the finest gold. The doors were also covered with gold: all the utensils in the house were of that metal; and even the floor appears to have been overlaid with it (1 *Kings*, vi. 30). It is this lavish expenditure of precious metal upon the building, and the elaborate workmanship bestowed upon it, which, rather than its architectural effect, accounts for the reports of its surpassing magnificence, and for the immense wealth consumed in its erection. The popular impression concerning it, however, being based rather upon the exaggerated statements of Josephus than upon the more sober accounts in Scripture, does, no doubt, greatly exceed the truth. More might be said of its richness than of its grandeur. Its wealth is indeed attested by the spoliations of successive kings and conquerors; and it may be well to remember that this was not, as in other nations, one of many temples, but was the sole temple of the whole nation, and in the production of which the whole nation could therefore concentrate its resources.

The Temple of Solomon retained its pristine splendour only for forty years, when its treasures were plundered by Shishak, king of Egypt. After undergoing various other profanations and pillages, it was finally destroyed by the Chaldæans under Nebuchadnezzar, B.C. 588, after having stood 417 years. After the Captivity, the temple was rebuilt, on the same plan, and on a more extensive scale, but with greatly diminished splendour. This temple stood until some years before the birth of Christ, when Herod the Great, to propitiate his subjects, whom most of the measures of his reign had tended to exasperate, undertook to rebuild it on a larger scale and with greater magnificence. In nine years, during which 80,000 workmen were constantly employed, he accomplished his original design; and produced a fabric, which, while the same in its essential characteristics, much surpassed the Temple of Solomon in extent and architecture, although the precious metal may have been less lavishly displayed in the interior decorations. Many years after, the Jews kept workmen employed in embellishing the pile, and in the erection of additional buildings (*John*, ii. 20). In A.D. 64, nothing remained to be done, and the dismissal at

once of 18,000 workmen excited some alarm for the part they might take in the troubles which had already commenced, and which, a few years after, brought upon the nation the armies of Rome under Vespasian and Titus, and involved the temple and city of Jerusalem in one common ruin, A.D. 70.

TEMPLE, SIR WILLIAM, an eminent statesman, diplomatist, and writer, was born at Blackfriars, in London, in the year 1628, and was the eldest son of Sir John Temple, who was Master of the Rolls in Ireland, and author of a History of the Irish Rebellion which began in 1641. He was educated first by his uncle, Dr. Henry Hammond, a learned divine and zealous royalist, and was afterwards, on his uncle being turned out of his living by the parliament, sent to a school at Bishop-Stortford, and, at the age of seventeen, to Emmanuel College, Cambridge, where the celebrated Cudworth was his tutor. He is said by his sister, Lady Giffard, who wrote a memoir of him, to have passed a gay idle life at Cambridge, and, after having been there about two years, he went away without a degree. He then went abroad, and having spent two years in France, and visited Holland, Flanders, and Germany, he returned to England, skilled in the French and Spanish languages. As he was about to start on his travels, he met, in the Isle of Wight, the young lady to whom, after many delays and difficulties, arising out of want of fortune and the opposition of the friends of both, he was eventually united. She was the daughter of Sir Peter Osborne, a devoted adherent of Charles I., and a great sufferer by his devotion; letters of hers which are preserved show her to have been a very superior woman: she remained faithful to Temple through a long engagement, amid many and great discouragements, and at last, after the death of her father, and after six years' waiting, they were married in 1654. It appears that, among many offers which she rejected for Temple, was one from Henry Cromwell.

Temple was trained to no profession, though his father was poor, independently of his appointment as Master of the Rolls in Ireland, and when deprived of this for some years during the civil wars, was exceedingly hampered in his finances. Sir John Temple was restored to this appointment in 1653, the year before his son's marriage; and his son, after his marriage, resided with him in Ireland. Under his father's roof in Dublin, or in a country-seat in the county of Carlow, Temple passed five years, which were divided between literary pursuits and county business, and which were marked by the birth and death of five children. In 1660 Temple was chosen, without solicitation or even previous knowledge, member of the Irish convention of that year for the county of Carlow.

After the Restoration he was re-elected for the same county in the first regular parliament that was called: he had his father for his colleague, and a younger brother was member for the city of Carlow. He appears to have been a very active and useful member of parliament. In July, 1661, he was one of the commissioners sent to wait on the king, and urge several measures affecting the interests of Ireland. On the prorogation of the parliament in 1663, Temple went to reside in England. He carried an introduction from the duke of Ormond to Lord Arlington, secretary of state, who conceived a great fondness for him, and procured him to be appointed, in 1665, on a secret mission to the bishop of Münster. The object of this mission was to watch over an invasion by the bishop of Münster of the United Provinces, towards which England, then at war with the Dutch, had guaranteed a subsidy; and though the bishop, who had made the first advances to England, went off from his engagement, and, in fear of France, concluded a separate treaty with the Dutch, Temple was not in any way to blame for this failure of the object of his mission. Indeed his employer was so satisfied with the way in which he had acquitted himself in his first diplomatic employment, that he was appointed in the same year, through Lord Arlington's influence, resident at the vice-regal court of Spain at Brussels.

Temple's residence at Brussels for two years presents no feature of peculiar interest. It was his business at first to watch over the neutrality of Spain in the Dutch war, and assist in cultivating a good understanding between Spain and England, with a view to a treaty which was then being negociated at Madrid, but which never came to pass, and subsequently to bring about peace with the United Provinces and with France. This last object was accomplished in July, 1667, by the treaty of Breda, which however Temple had no part in negociating, and the mode of bringing about which he had not altogether approved of. In 1666 Temple's services had been rewarded, without any solicitation on his part, by a baronetcy.

In the close of the year 1667 Temple received orders from Arlington to repair to the Hague, to negociate a treaty against France, and for the protection of the Spanish Netherlands from that power; and by his energy, judgment, and address the celebrated Triple Alliance was concluded on the 23rd of January, 1668. England, Holland, and Sweden bound themselves by this alliance to bring about peace between France and Spain, and to prevent France from entering the Low Countries. Temple had thus achieved an object which he had had at heart, even before the treaty of Breda, so favourable to French views, a blow to the ambition of Louis XIV. The successful conclusion of this treaty established Temple's diplomatic fame, and was of the first importance to England and Europe.

Temple was next appointed ambassador at Aix, where the negociations for peace between France and Spain, in pursuance of the Triple Alliance, were to be carried on. On the conclusion of the peace of Aix, he was appointed ambassador at the Hague. Here he continued, carrying out the policy of the Triple Alliance, till September, 1670, when a complete change having been silently worked in the councils of Charles II., and the celebrated secret treaty having been made with France, Temple was ordered home, found himself on his arrival in England no longer in the confidence of Arlington, and in the summer of 1671 was dismissed from his post. There was a rumour that Temple's dismissal had been made a condition by the French government. (Temple's *Works*, ii., 179.) He now retired to Sheen, and meditated never again returning to public life, saying that 'he had been long enough in courts and public business to know a great deal of the world and of himself, and to find that they were not made for one another.'

During this retirement Temple devoted himself to gardening, the improvement of his house at Sheen, and literature, and published several of the works on which his reputation as a writer rests; among them, the 'Observations upon the United Provinces,' published in 1672. Temple was summoned however from his literary retirement in the summer of 1674, to conclude the second Dutch war, and he obeyed the summons. He was on the point of starting for the Hague, as envoy and plenipotentiary for this purpose, when the Spanish ambassador in London received full power to negociate there, and in three days the treaty of Westminster was concluded. Temple was now offered the embassy to Spain, which, at his father's wish, he refused. He was very soon after appointed again to the Hague, as ambassador extraordinary, and the next year ambassador to the congress at Nimeguen. The peace of Nimeguen, concluded in the beginning of 1679, ill carried out the views which Temple assiduously laboured to establish, and he was glad to avail himself of a point of form for the purpose of withholding his signature to the treaty.

Temple now returned to England to receive an offer of the post of secretary of state, which he refused. He was much consulted by the king, who had just lost the services of Lord Danby; and in the ministerial difficulties which followed upon Danby's impeachment and committal, Temple submitted to the king a plan of a council, which the king adopted: not always following Temple's opinions however as to the persons of whom it should be composed, and, above all, in defiance of his advice, placing Lord Shaftesbury at the head of it. This council was not long-lived, but it did not die until after its author had been removed from it. [CHARLES II.]

Thus ended Temple's political career. The remainder of his life was passed in the country, and divided between learning and rural pursuits. He now composed his 'Memoirs.' He died on the 27th January, 1699. No particulars of his death have been transmitted to us.

After the Revolution of 1688, Sir William Temple refused office from William III., who was very anxious for his counsel and for the authority of his name. But his son, with his permission, accepted the place of secretary at war, and within a week after committed suicide.

Neither as statesman nor as author does Sir William Temple occupy a foremost place; but in both characters he is more than respectable. The following is a happy

description, by Sir James Mackintosh, of his character as diplomatist and statesman. 'He was a most admirable person. He seems to be the model of a negotiator, uniting politeness and address to honesty. His merit as a domestic politician is also very great: in an age of extremes he was attached to liberty, and yet averse from endangering the public quiet. Perhaps diplomatic habits had smoothed away his turbulence too much for such a government as England.' (*Life of Mackintosh*, ii. 199.) Dr. Johnson, speaking of Sir William Temple as a writer, has said that 'he was the first writer who gave cadence to English prose.'

There are two or three biographies of Temple; one by Abel Boyer, published about fourteen years after his death, and another by his sister, Lady Giffard, prefixed to the edition of his works published in 1731, 2 vols. folio. A very laboured and somewhat diffuse life has been lately published by the late Mr. Peregrine Courtenay, and to this work all who wish for the fullest information as to Temple's life will resort. The best edition of Temple's works is that published in 1814, in 4 vols. 8vo.

TENACITY (from the Latin 'tenacitas,' 'the power of holding'), a property of material bodies by which their parts resist an effort to force them asunder.

This property is a result of the corpuscular forces acting within the insensible spaces supposed to exist between the particles of bodies: it is consequently different in different materials, and in the same material it varies with the state of the body with respect to temperature and other circumstances.

Those corpuscular forces consist of attractions which vary according to unknown laws with the distances of the particles from one another, and even at certain distances they become repulsions; but, in all bodies except the elastic fluids, the combined actions of all the particles produce that coherence which constitutes the tenacity of the masses. In those fluids the particles have no coherence, and when the pressures to which they are subject are removed, those particles immediately separate from each other with forces depending, probably, upon the quantity of caloric with which they are combined. In non-elastic fluids and in solids, tenacity exists, but in very different degrees; its force depending upon differences in the intensity of the attracting powers between the particles, upon differences in the distances of the particles themselves, upon the action of the caloric, and, in some cases, upon variations in the pressure of the atmosphere.

The molecules of liquids adhere to one another, and generally to those of solid bodies, by attractive forces which decrease very rapidly; and, at insensible distances from the supposed places of contact, the adhesion entirely disappears [Capillary Attraction]: the real tenacity of the molecules being, as Dr. Young observes, equal to the excess of their mutual attractions above the forces of repulsion arising from the actions of the calorific particles. It is on account of the small distance to which the attractions of the fluid molecules extend, and to the freedom with which the particles move on one another, that fluids appear to have so little tenacity; but from the weight of water which it supports in glass tubes, Dr. Robison has estimated that the mutual attractions of the particles of water on a surface equal to one square inch must far exceed 190 pounds.

Grains of dust or sand, while dry, have no power of adhering together, probably because their forms do not permit a sufficient number of points on their surfaces to be brought within the distance at which corpuscular attractions take place; but, if slightly wetted, the mutual attractions between the dust and the liquid produce a certain degree of tenacity: this is very sensible in clay moistened with water; for being then drawn into the form of a rod, it is capable of bearing a small weight suspended from it. Tenacity exists in various degrees in viscid fluids, as oil, gum dissolved in water, &c.: sealing-wax and glass also, when heated, lose their brittleness, and are capable of being moulded into any form, while their particles retain a considerable degree of adhesive power.

The tenacity of solids constitutes, in part, the subject of the power of bodies to resist strains; and under Materials, Strength of, will be found a table (p. 8, col. 2) of the weights which would overcome the force of cohesion in rods immoveably fixed at one end and pulled in the direction of their length: those weights may be considered as the measures of tenacity in the different kinds of material; and it may be here added that, from a mean of several experiments made by Mr. Telford on the tenacity of forged iron, the breaking strength, when reduced to that which it would be if the area of a transverse section of the bars had been one square inch, is 29¼ tons. The bars were cylinders or parallelopipeds varying in length from 1 foot 5 inches to 2 feet 3 inches; and in area of section, from 0·56 to 3·14 square inches: they stretched in length from 2 inches to 4 inches before they broke. Mr. Telford found also that a bar of cast-steel bore suspended from it 27·92 tons, a bar of blistered steel 17·27 tons, and of cast-iron (Welsh, pig) 7·26 tons; the area of the section in all being one square inch. Tenacity in solid bodies varies greatly with their temperature. M. Coulomb took a piece of copper-wire, which, when cool, carried 22 lbs. suspended from it; and, upon bringing it to a white heat, it would scarcely bear 12 lbs.

Though, when a piece of metal is fractured, the parts will not by simple adjunction adhere together; yet, in some cases, by hammering them upon one another, so many points on their surfaces may be brought within the limits to which the force of cohesion extends, that they will acquire a tenacity equal to that which the metal had in its natural state.

The tenacity of wood is much greater in the direction of the length of its fibres than in the transverse direction, the fibres being united by a substance having little cohesive power. Few experiments have been made on the tenacity of wood perpendicularly to its grain, as it is called; and from those of Mr. Emerson it appears to vary from one-tenth to one-seventh of the tenacity in the other direction. When a strain takes place in the direction of the fibres, they become disengaged from one another, and thus lose the strength which arises from their lateral cohesion: they then become subject to separate strains; the weaker ones are first ruptured, and at length all give way, leaving an irregular surface of fracture.

With respect to metals, the processes of forging and wire-drawing increase their tenacity in the longitudinal direction; the augmentation of friction and lateral cohesion, arising from the particles being forced together in the transverse direction, more than compensates for the diminution of the attraction which may result from the particles being forced or drawn farther asunder longitudinally. Copper and iron have their tenacity more than doubled, while gold, silver, brass, and lead have it more than tripled by those metals being drawn into wire.

Mixed metals have, in general, greater tenacity than those which are simple: the tenacity varies with the different proportions in which the metals are mixed; and the proportions which produce the greatest strength are different in different metals. The only experiments on this subject with which we are acquainted are those of Muschenbrock; and from these we find that a compound of which ⅔ were gold and ⅓ copper had a tenacity, or force of cohesion, more than double that of the gold or copper alone: brass, composed of copper and zinc, had a tenacity more than double that of the copper, and nearly twenty times as great as that of the zinc: a metal of which ⅔ were block-tin and ⅓ lead, had a strength more than double that of the tin; and a mixture of which ⅔ were lead and ⅓ zinc had a tenacity nearly double that of the zinc, and nearly five times as great as that of the lead alone.

TENAILLE, in Fortification, is a rampart raised in the main ditch, immediately in front of the curtain between two bastions; and, in its most simple form, it consists of two faces coinciding in direction with the faces of the bastions, and, consequently, forming with each other a re-entering angle. Generally, however, it consists of three faces, of which two have the directions just mentioned and the third forms a curtain which is parallel to that of the enceinte. See P, *Fig.* 1, Bastion, and I' (in the plan, p. 377), Fortification.

This work was originally proposed by Vauban, in order to serve the purpose, in part, of a fausse-braye [Fausse-braye], since the fires of musketry on its faces may be employed, in conjunction with those of artillery and musketry on the flanks of the bastions, to oppose the passage of the enemy across the main ditch when about to mount a breach in the ramparts of the place.

The relief of the tenaille, or the elevation of its crest above the bottom of the ditch, is determined consistently

with the intention of thus defending the main ditch; and in order that the defenders of the tenaille may not be injured by the shot fired over their heads, from the flanks of the bastions, it is usual to make the crest of that work coincide with a horizontal plane passing three or four feet below the point where a line of fire from one of those flanks would cut a vertical plane, bisecting the angle of the tenaille or its curtain. The height thus determined will allow the parapet of the work to be elevated from two to four feet above the terreplein of the ravelin in its front; and, consequently, from the curtain of the tenaille a grazing fire of musketry might be employed to protect the interior of the ravelin, or of its reduit, if there is one, should the defenders of either of those works abandon it (in consequence of an assault being made) before the enemy has time to cover himself in it by a lodgment: that fire will also contribute powerfully to prevent the enemy from attempting to enter the ravelin by its gorge.

Vauban, at first, gave to his tenailles short flanks nearly parallel to those of the bastions, but he soon abandoned that construction, perceiving that though the defenders might thus fire correctly along the main ditch, yet the parapets of those flanks were liable to be destroyed by the fire from the enemy's counter-batteries [H, *Fig.* 1, Bastion], and they were enfiladed from the rampart of the ravelin (Q), or from the glacis of the places of arms (L).

Besides affording additional fires for the defence of the main ditch, the tenaille serves to cover, in part, the revetment of the curtain in its rear, and prevent it from being breached by fire from any lodgments of the enemy on the glacis. Its parapet serves also to mask the postern in the curtain of the enceinte, which would otherwise be so much exposed to the fires from the counter-batteries, that the defenders might be unable to communicate through it with the outworks. On this account the breadth of the ditch between the curtain of the tenaille and that of the enceinte is made such only as to allow the parapet of the former, with the relief determined as above mentioned, to conceal the postern from the view of the enemy on the glacis. This ditch is advantageous in preventing the defenders of the tenaille from being injured by the splinters which may be detached from the flanks and curtain behind it; and, when dry, it serves to cover bodies of troops which may issue from thence and attack the enemy while crossing the main ditch, previously to making an assault. If the main ditch contains water, the tenaille serves to cover the boats and rafts by which the defenders of the enceinte communicate with the outworks.

The tenaille has been considerably improved by Bousmard, who, returning, in one respect, to the original idea of Vauban, has given flanks to the work in order that the main ditch may be directly defended by them. These flanks are raised high enough to cover the revetments of the flanks of the bastions, while their upper surfaces may be grazed by a fire of artillery from thence; and, instead of being formed with open terrepleins, and parapets for musketry, as usual, each flank of the tenaille is provided with casemates, or vaults, for four pieces of artillery which are placed nearly on a level with the terreplein of the covered-way. These guns are consequently capable of being directed against the counter-batteries (H) of the enemy, as well as of defending the foot of a breach in the face of the bastion.

This construction was adopted by Chasseloup de Laubat in the tenailles of the detached works which he executed about Alessandria, in Italy, when Napoleon (after the battle of Marengo) proposed to make that city the base of his operations beyond the Alps. But, in order to avoid the mischief which results from a fire directed against casemates (the shot in striking the cheeks or sides of the embrazures detaching from them splinters, which being driven into the vault do more injury to the defenders than the shot itself), this engineer raised before each flank of the tenaille a mass of earth which was reveted with brickwork, and perforated in such directions that, in defending the ditch, the shot from the casemates could be fired through the apertures, while the mass served as a mask which would prevent the enemy from seeing the embrazures in the flanks of the tenaille.

Belidor, in his 'Science des Ingenieurs' (1729), proposed tenailles with each face in the form of a circular arc, extending between the curtain and the shoulder of the bastion. But this construction, to which the name of 'ram's horns' was given, has seldom been put in practice.

Any work belonging either to permanent or field fortification, which, on the plan, consists of a succession of lines forming salient and re-entering angles alternately, is said to be *à tenaille*.

TENAILLON, or Great Tenaille, in Fortification, is a species of exterior work which has been occasionally constructed before the faces of a small ravelin, with a view of increasing the strength of the latter, procuring additional space beyond the ditch, or covering the shoulders of the bastions. They were invented by Vauban, who, however, very seldom constructed them; and subsequent engineers have generally considered them as inferior in defensive qualities to a counterguard [QQ, Fortification, *Fig.*, p. 377] placed over the faces and salient angle of the ravelin.

The form and position of a tenaillon may be understood, Y being supposed to represent a small ravelin, if beyond the ditch of the latter the ramparts of the right and left faces be produced till each of them meets a rampart nearly perpendicular to the face of the bastion and extending to the place of meeting from the counterscarp of the main ditch at a point opposite the middle of that face. The works thus formed, one over each face of the ravelin Y, constitute a tenaillon; before each line of rampart is a ditch, and part of the general covered-way, the main ditch and that of the ravelin being in the rear. The two faces which are beyond the salient angle of the ravelin would, if produced towards the latter, form with each other a re-entering angle, whose vertex would coincide with that of the said angle.

The objections to tenaillons are, that the besieger would experience little difficulty in establishing a lodgment on that part of the covered-way or glacis which is immediately in front of the salient angle of the ravelin; and in this situation he would be able to breach the faces of the two half-bastions in four places, by fires of artillery directed along the ditches of the ravelin and those on the side faces of the tenaillon. The salient angles of the tenaillon, and of the ravelin which it covers, may be breached at the same time, and, when the ditches are dry, it would be possible to attack and carry the ravelin at the time of making the assaults on the tenaillon: then, the enemy having got possession of the former work, any retrenchments which may have been made in the tenaillon must necessarily be abandoned by the defenders.

At the siege of Lille, in 1708, one of the tenaillons held out a long time, but this is ascribed by French engineers rather to the faulty manner in which the siege was conducted by the allies than to the strength of the work.

The re-entering space between the two faces which are in the prolongation of the faces of the ravelin, and which constitute the head of the tenaillon, is sometimes occupied by a small redoubt, consisting of two ramparts perpendicular to the faces which have been just mentioned; and thus there may be obtained a good crossing fire for the defence of that part of the covered-way which is concealed by the salient angles of the tenaillons from the defenders of the bastions.

Demi-tenaillons are works placed also on the sides of a ravelin, and consisting of two ramparts which are perpendicular to and nearly opposite the middle of the faces of the bastions and ravelins: these are usually accompanied by counterguards which cover the salient angles of the latter works, and are called *Bonnets*.

TENANCY. [Tenant.]

TENANT. [Tenure.] Tenants, in the more extended legal sense of the word, are of various kinds, distinguished from each other by the nature of their estates; such as tenants in fee simple, in fee tail, for life, &c. [Estate; Tenant in Fee Simple, &c.]

TENANT AND LANDLORD. The word tenant in the more limited legal sense, which is also the popular sense, is one who holds land under another, to whom he is bound to pay rent, and who is called his landlord. The present article is confined to this sense of the word, in which it is proposed to show the nature, construction, and effect of the contract by which the relation of landlord and tenant is created; the rights, liabilities, and duties of each under it; how it ceases or may be terminated; and the legal means by which the rights and duties of each may be enforced.

The word land is here used in its comprehensive legal sense, which means not only the actual land itself, but also all things, such as buildings, woods, and water, which may be upon it. Any one who has an estate in land, provided he is also in possession, may let the land to another. The character and duration of the letting are partly regulated by the nature of the interest of the lessor or landlord and partly by the contract of letting. Thus one who is the owner of land in fee simple may let the land for any limited period, while one who holds only for life cannot let for any longer period than the life upon which his estate depends, unless he has a special power to grant leases; and if he should let for any longer period, the interest of the tenant will cease on the expiration of the life. To constitute the relation of landlord and tenant, the period for which the land is let must be shorter than that during which the land is held by the lessor, so that the lessor may have a reversion. If he parts with his whole interest, he is an assignor, not a lessor. Where the letting takes place by an express contract between the parties, the contract is called a lease. [LEASE.] A lease may be made by deed, by writing without deed, or by a mere verbal agreement. By the 29 Ch. II., c. 3, s. 1, all leases, estates, &c. in land, &c. not put into writing, and signed by the parties so making or creating the same, or their agents thereunto verbally authorized or by writing, shall have the force and effect of leases or estates at will only, and shall not either in law or equity be deemed or taken to have any other or greater force or effect, &c. The second section of this act makes an exception in favour of 'all leases not exceeding the term of three years from the making thereof, whereupon the rent reserved to the landlord during such term shall amount unto two third parts at least of the full improved value of the thing demised.' Under the construction which this statute has received, an unwritten lease for a longer period than three years will create a tenancy from year to year, and the terms as to rent, &c. upon which the tenant holds will be those which are agreed upon in the unwritten lease. The loss of a lease will not destroy the tenancy, provided the previous existence and the terms of it can be proved.

But the relation of landlord and tenant may be created otherwise than by a formal lease. If one man with the consent of another occupies his land, a contract of letting is assumed to have been made between them, and the occupier becomes tenant to the owner. Formerly such tenants were called tenants at will, and might have been turned out at any time by the landlord; but now a more convenient and reasonable construction of their occupation prevails, and they are considered to be upon the same footing as if the lands had been let to them for a year dating from the commencement of their occupation. At the end of the first year, a second year's tenancy begins, unless six months' notice of the intention to determine the contract has been given by either party to the other, and so on from year to year. The same construction is applied to cases where a tenant continues to occupy land after the expiration of a lease made by deed; but in this case all the covenants of the expired lease as to payment of rent, repairs, insurance, and the like are held to be in force unless the lease is cancelled by destroying the seal; and even if there should be a verbal agreement for a different rent, still the old covenants subsist, unless the lease is cancelled. If a party who has the power to set aside an existing lease chooses to receive rent under it, he will be held to have confirmed it; and even where a lease has determined, as a lease granted by a tenant for life for a longer period than he was entitled to grant one would become upon his death; yet if the remainder-man or reversioner has allowed the tenant to lay out money on the premises, he will be prevented by a court of equity from disputing the lease.

Besides tenancies for fixed periods, a tenancy may exist at Will and by Sufferance. [TENANT AT WILL; TENANT AT SUFFERANCE.] A tenant at will cannot lawfully be turned out of possession, nor can the landlord succeed in an action of ejectment against him, till after a demand to quit has been made upon him by his landlord; but a tenant by sufferance may be turned out by an action of ejectment without any demand. A master may let land to his servant, but where the servant is allowed by the master to occupy premises belonging to him for the mere purpose of more conveniently performing his duties as servant, or as in part or total payment of wages, the servant does not therefore become a tenant, and the premises are considered to be in the occupation of the master. The law as to landlords and tenants generally applies also, so far as it is not restricted or varied by the particular circumstances of the contract between the parties, to the case of the letters and occupiers of lodgings.

In every case where the relation of landlord and tenant exists, either by express or by implied contract, certain terms are implied by law to have been agreed upon by the parties as forming part of the contract. It is of course in the power of the parties, where the contract is express, to qualify these terms so implied by the language of the contract itself. But it may be observed that as these terms are comprehensive in their nature, and distinctly understood in law, the interests of parties are often better consulted by leaving them to the general protection afforded by these implied terms than by attempts to define by enumeration in detail the respective rights and duties of the landlord and tenant. The terms implied on the part of the landlord are, that the tenant shall quietly enjoy the premises; on the part of the tenant, that he will pay rent, keep the premises in repair to a certain extent, as hereafter mentioned, and use the land, &c. in a fair and husbandlike manner.

As a general rule it may be laid down that the tenant is not entitled to set off against his rent, debts due from the landlord to him; but there are some exceptions. When the landlord is himself tenant of the premises to a superior landlord, and neglects to pay his rent, and the occupying tenant is called upon to pay it to the superior landlord, he may do so, and set it off against the rent due from him to his own landlord. Payments also made by the tenant under the land-tax act (38 Geo. III.) may be set off against the rent due to his landlord. When a landlord is bound to repair, and the tenant, in order to prevent further dilapidations himself, expends money on the repairs, or the landlord has undertaken to repay the tenant the amount of rates and taxes, &c. paid in the first instance by him, the tenant may set off. If a tenant has covenanted without exception or reservation to pay rent during the term for which the lease has been granted to him, he will be bound to pay it even although the premises should be entirely destroyed by fire or other casualty; and even although he should have assigned his lease to another and ceased to be in possession, he will still remain liable under his covenant to pay rent. But the party to whom he has assigned it will, as a general rule, remain liable for rent to the original landlord only so long as he continues in the possession of the premises.

Generally, the tenant is bound to repair the premises. Repairs have been divided into two kinds, substantial repairs and ordinary repairs. The division appears a very simple one, but great difficulty often occurs in practice in determining to which kind any particular item of repair belongs. Tenants for a long term of years are said to be liable for substantial repairs, such as beams, roofing, &c.; tenants from year to year are liable only for ordinary repairs, and for injuries caused by their own negligence. A landlord is in no case, unless under a special agreement to that effect, liable to any action for not repairing nor even for not rebuilding where there has been a total destruction of the premises. But in the case of short tenancies, if the landlord should not rebuild or do the substantial repairs necessary, the tenant would be justified in quitting the premises and would cease to be liable for rent. It has been already observed that a tenant under a lease which contains covenants to repair, who by holding over and paying rent after the expiration of his lease becomes a yearly tenant, will still be liable to repair in the manner provided for by the covenants. Such a tenant, therefore, though only a yearly tenant, may be liable to do substantial repairs; and if he wishes to avoid such a liability, he should guard against it by an express agreement. In the case also of a lease which though invalid has been acted on by the parties as if valid, the covenants of the lease will be looked to for the purpose of determining what are the duties and liabilities of the parties as to repairs, &c. No tenant, in the absence of an agreement to that effect, is bound to rebuild after accidental destruction of the premises by fire. But under a general covenant to repair, and *leave repaired*, the tenant is bound to rebuild even in the case of destruction by fire. Cove-

nants to repair are said to be construed by the courts favourably for the landlord, but the tenant is not bound to counteract the natural consequences of the wear of time and of the elements.

In agricultural tenancies the lease itself generally determines the mode in which the farm is to be treated, and the meaning of the expressions used will be ascertained by the construction put upon them by persons familiar with husbandry. Unless also the lease expressly or impliedly excludes the operation of the custom of the country, the tenant is bound to conform to it. The custom of the country means the general practice employed in neighbouring farms of a similar description, with reference to rotation of crops, keeping up fences, and other like matters. In leases of farms it is often the practice to protect the landlord against certain acts of the tenant, such as ploughing up meadow land, &c., by introducing certain provisions into the lease. These provisions may operate according to the phraseology used, either to assign a penalty or to determine the liquidated damages agreed to be paid for the act done. It is often a matter of great importance and of some nicety to determine under which class the provisions fall. If under the first, the landlord is not entitled to the whole penalty upon the act being done, but he can only recover in an action the amount of the actual damage which has accrued. If under the second, he is entitled to the whole amount of the damages agreed on. A covenant by a tenant not to plough up meadow under a penalty of 5*l*. for every acre ploughed, is an instance of the first class: a covenant to pay 5*l*. rent for every acre of meadow ploughed up, is of the second class. The right to timber and timber-like trees belongs to the landlord; loppings of pollards and bushes, to the tenant. Different definitions prevail in different counties of timber and timber-like trees, and various customs prevail as to what amount of wood the tenant may be allowed to employ (after the landlord has been called on to select it) for the purposes of the farm. No tenant, unless he employs the land as a nurseryman or gardener, can remove any kind of shrub from the soil, not even a row of garden box, though planted by himself. [Waste.] Neither can a tenant remove fixtures, though put down by himself. A fixture is a chattel which is itself let into the soil, or united to some other which is let in. There are some exceptions to this rule in favour of fixtures used for the purpose of trade or agriculture, or merely ornamental purposes, where the removal will cause little or no damage. (Amos and Ferard, *On Fixtures*.)

The tenant in occupation of the premises is, in the first instance, liable for all taxes and rates of every description due in respect of the premises. The party therefore who is authorised to collect them may proceed against the tenant in occupation to recover them. It is generally a matter of agreement between the landlord and tenant that the tenant shall pay all rates and taxes except the land tax. If however the landlord has undertaken to pay the tenant the rates and taxes, and fails to do so, the tenant may deduct the amount from his rent, or bring an action to recover it; but this should be done during the current year, and if the tenant allows a considerable time to elapse without claiming a deduction or bringing an action, he will be held to have waived his claim to recover them from the landlord.

Where a fixed rent has been agreed upon, has become due, and is neither paid nor tendered, the landlord, under the exceptions mentioned hereafter, has a right to seize growing crops, any kind of stock, goods, or chattels, upon the premises, or pasturing any common enjoyed in right of the premises, whether such things are the actual property of the tenant or not; and if the rent remains unpaid, he may sell them. The exceptions are: Things in actual use, as clothes then being worn, or a horse on which a person is actually riding. The reason given for these exceptions is that the seizure of goods so circumstanced would lead to a breach of the peace. Things sent to a tradesman for the purpose of being worked up by him; goods sent by a principal to his factor for sale, and the beasts or carriages conveying them; the goods and cattle belonging to guests at an inn; goods that are already in the custody of the law, such as goods in a bailiff's hands under a writ of execution, &c. The tools, &c. of a man's trade, beasts of the plough, &c., are not liable to distress if there are other goods sufficient in value upon the premises. [Distress.]

The contract of letting may cease otherwise than by the mere lapse of time. By 29 Ch. II., c. 3, the Statute of Frauds, a surrender of a lease can only be by a deed or note in writing, signed by the party surrendering or his agent authorised in writing, or by act and operation of law.

The deed or note in writing must proceed upon mutual agreement between the tenant in possession and his immediate landlord, and, besides being signed, must be duly stamped. A lease may cease to exist by act and operation of law: 1, upon the acceptance by the tenant of a new lease in writing for the same premises from the landlord, the operation of which is to begin at some period during the term for which the original lease was granted; 2, in the case of a yearly tenancy, where the landlord permits the tenant to quit, and he does quit, and the landlord accepts the possession; 3, where the estate of the landlord and tenant become united in the tenant, the tenancy ceases to exist; 4, by forfeiture. A forfeiture may arise either by a breach by the tenant of one of those conditions which are implied by or attached to the relation of landlord and tenant, as where a tenant disclaims or impugns the title of his landlord by acknowledging, for instance, the right of property to be vested in a stranger, or asserts a claim to it himself, or by a breach of a condition which is expressly introduced into the lease, the breach of which is to be attended with a forfeiture of the tenancy, as a condition to pay rent on a particular day, to cultivate in a particular manner, &c. To this head may be referred provisoes in a lease for re-entry by the landlord on the doing or failure to do certain acts by the tenant, such as the commission of waste, the failure to repair, &c. The courts are said to be unfavourable to forfeitures; therefore, when the landlord has notice of an act of forfeiture, or an act which entitles him to re-enter, he must immediately proceed in such a way as to show that he intends to avail himself of his strict legal right. If after the commission of the act he does anything which amounts to a subsequent recognition of the tenancy, as by the acceptance of rent subsequently due, he will be held to have waived his right to insist upon the forfeiture.

A yearly tenancy, where no period of notice is agreed on, must be determined by a notice to quit at the expiration of the current year, given six months previously. If the period at which the current year expires is uncertain, the notice should be to quit at the end of the year which shall first occur after the expiration of six months from the service of the notice. Where a fixed period of notice is agreed on, what has been said as to the period will apply to the period agreed on. Where different portions of the premises have been entered on at different times, the entry upon the principal portion will, for the purposes of quitting the premises, be considered as the entry upon the whole; and in case of a dispute at a trial which is the principal portion, the jury must determine. In the case of lodgings, the time, when less than a year, for which they are taken, will be the time for which a notice is necessary. Thus lodgings taken by the month or week require a month's or week's notice. A notice to quit may be waived by an acceptance of rent or by a distress for rent due after the expiration of the notice.

If by the default of the landlord the premises cannot be occupied beneficially, as where the landlord is bound to repair, &c., and does not, the tenant may quit without notice.

The notice to quit need not be in writing, though, from the greater facility of proving it, a written notice is always desirable. It should distinctly describe the premises, be positive in its announcement of an intention to quit or require possession, be signed by the party giving it, and served personally upon the party to be affected by it.

If a tenant, after having given notice to quit, continues to occupy, he is liable to pay double rent. If he does so, no fresh notice is necessary. If he continues to occupy after the landlord has given him notice, he is liable to pay double value for the premises.

At the expiration of the contract the tenant is bound to deliver up possession of the premises; but if either by special agreement or by the custom of the country the tenant is entitled to the crops still standing on the land, and which are called away-going crops, he may enter for

the purpose of gathering them, and also use the barns and stables for the purpose of threshing and conveying them away. The in-coming tenant may also enter during the tenancy of the preceding tenant to plough and prepare the land.

An action for the recovery of rent may, if the land is let by lease under seal, be in debt for the amount, or in covenant for the damages incurred by the non-payment of it. If there is no indenture, the action may be in debt on the simple contract, or in assumpsit for the use and occupation of the land.

If the tenant refuses to deliver the possession of the land, the landlord may bring an action of ejectment to recover it. By 4 Geo. II., c. 28, which was passed with a view to remove the difficulties existing under the common law as to the necessity for a formal entry, &c. by the landlord, it is enacted that where there is half a year's rent in arrear, no sufficient distress on the premises, and the landlord to whom the same is due has a right of re-entry, he may, without any formal demand or re-entry, serve a declaration in ejectment, which shall stand in place of the same.

By the 11 Geo. II., c. 19, and 57 Geo. III., c. 52, if a tenant, under any lease or agreement, written or verbal, though without a clause of re-entry, of lands at a rack-rent, or rent of three-fourths the yearly value, shall be in arrear for half a year's rent, and shall leave the premises deserted and without sufficient distress, any two justices of the county, at the request of the landlord, may go and view the premises, and fix on the most conspicuous part of them notice in writing on what day, distant fourteen days at least, they will return again to view the premises; and if on the second day no one appears to pay the rent, and there is no sufficient distress on the premises, the justices may put the landlord into possession, and the lease shall become void. These proceedings are subject to appeal before the judges of assize for the same county at the ensuing assizes.

By 1 & 2 Vic., c. 74, where the interest of any tenant of land, &c. at will, or for a time less than seven years, liable to the payment either of no rent or a rent of less than 20*l.* a year, shall have ended or been duly determined, and the tenant shall refuse to quit, the landlord may serve him with a notice, a form for which is given in the act, to appear before a justice for the county; and if he fails to show satisfactory cause why he should not give up possession, the justices, on proof of the tenancy and of the expiration of it, may give possession to the landlord. If the landlord was not at the time of the proceedings lawfully entitled to possession, he will be liable to an action of trespass at the suit of the tenant, notwithstanding the act of parliament.

(Woodfall's *Landlord and Tenant;* Coote's *Landlord and Tenant.*)

TENANT AT WILL, AND FROM YEAR TO YEAR. 'Tenancy at will,' says Littleton, s. 68, 'is where lands or tenements are let by one man to another to have and to hold to him at the will of the lessor, by force of which lease the lessee is in possession. In this case the lessee is called tenant at will because he hath no certain or sure estate; for the lessor may put him out at what time it pleaseth him.'

An estate at will may arise by implication, as well as by express words. Thus, where a tenant for years continues in possession after the expiration of his term, and pays rent as before, the payment and acceptance of rent constitute a tenancy at will. So, where a man enters under an agreement for a lease or a contract for the purchase of an estate, he must be considered at law as the tenant at will of the person who has the legal title. (10 Vin., *Ab.*, 400; 1 B. and C., 448; 3 Camp., 8.)

Where a mortgagor continues in possession of his land with the consent of the mortgagee, after default in payment of principal and interest at the time stipulated in the mortgage deed, he is tenant at will. So also, where the legal estate is vested in a trustee, the beneficial owner, or *cestuique trust*, if he be in possession, is considered at law as tenant at will under the trustee. (Cruise, *Digest*, tit. 9, c. 1, § 4.)

A tenant at will having no certain estate, has nothing which he can grant to another, and a person entering under a grant from a tenant at will is subject to an action of trespass. (Co. Litt., 57 a.)

A tenant at will has no right to commit any kind of waste; but, on the other hand, he is not liable to repair or sustain houses, &c., and therefore there is no remedy against him for permissive waste. (Co. Litt., 57 a; 5 *Rep.*, 13 b.)

A tenancy at will may be determined either by express declaration of the lessor that the tenant shall hold no longer, which must be made on the land, or notice given of it to the lessee (Co. Litt., 55 b.), or by some act of ownership exercised by the landlord inconsistent with the continuance of the estate, such as entering on the land and cutting down trees demised, making a feoffment, or a lease for years to commence immediately. On the part of the tenant, any act of desertion, an assignment of the land to another, or the commission of waste, is a determination of his estate. A lessor determining the tenancy before the rent is due loses the rent; and on the other hand, the lessee who determines it before the rent is due must notwithstanding pay it up to that time. If either party die, the tenancy, if it be of a house, continues till the next rent-day; and if of land, until the summer profits are received by the tenant or his representatives. (Co. Litt., 55 b, 57 a.)

Where a tenancy at will is determined by the lessor, the tenant is entitled to emblements; but not if it be determined by the tenant himself. (Litt., § 68; 5 *Rep.*, 116.)

It is settled that a landlord cannot bring an ejectment against the tenant at will or his representatives without giving six months' notice to quit. (Cruise, tit. 9, c. i., § 15.)

The courts are always inclined to construe demises where no certain term is mentioned, not as estates at will, but as tenancies from year to year; and the circumstance of an annual rent being reserved has been considered sufficient to warrant this construction. (2 Blackst., 1171.) Where a remainder-man receives rent from a tenant under a lease for years which is void as against him, before electing to avoid it, a tenancy from year to year is created. (7 *T. R.*, 478.) Also where an agreement for a lease for more than three years is made by parol, and is therefore void by the Statute of Frauds, there is a tenancy from year to year regulated by the terms of the agreement. (5 *T. R.*, 471.)

A tenancy from year to year, when once constituted, is binding not only upon the reversioner, but his assignee (1 *T. R.*, 378), and does not cease upon the death of the tenant, but goes to his executors or administrators. (3 *T. R.*, 13; 15 Ves., 241.) The tenant is entitled to six months' notice to quit, ending at the expiration of the year, and thus a new year is continually added to the term as often as the half year's previous notice is omitted to be given at the proper time. (3 B. and C., 483.)

A tenant at will is capable of taking a release of the inheritance after he has entered, but his estate cannot be the foundation of a remainder. (Litt., iii., 460; 8 Co., *Rep.*, 75 a.)

TENANT AT SUFFERANCE, says Lord Coke, 'is he that at first came in by lawful demise, and after his estate endeth continueth in possession, and wrongfully holdeth over.' Thus a tenant *pur autre vie*, continuing in possession after the death of *cestuique vie*, a tenant for years holding after the expiration of his term, and a person who, having been tenant at will, continues in possession after the death of the lessor, are all tenants by sufferance.

As the tenant at sufferance holds only by the laches of the owner, there is no privity of estate between them, and therefore the tenant at sufferance is not capable of taking a release of the inheritance. (Litt., § 460.) On the same ground it was held that tenants at sufferance were not bound to pay any rent; but by the 4 Geo. II., c. 28, § 1, it is enacted that 'where any tenant holds over after demand made and notice in writing given for delivering the possession, such persons so holding over shall pay double the yearly value of the lands so detained, for so long a time as the same are detained; to be recovered by action of debt, against the recovering of which penalty there shall be no relief in equity.' By the 11 Geo. II., c. 19, § 18, a similar penalty is imposed on tenants giving notice to quit and afterwards holding over. And by the 1 Geo. IV., c. 87, various provisions are made for enabling landlords more speedily to recover possession of lands and tenements unlawfully held over by tenants.

TENANT-RIGHT is the name for a species of customary estates peculiar to the northern parts of England, in which border services against Scotland were antiently performed before the political union of the countries. Tenant-right estates were holden of the lord of the manor by payment of certain customary rents and the render of the services above mentioned, are descendible from ancestor to heir according to a customary mode differing in some respects from the rule of descent at common law, and were not devisable by will either directly or by means of a will and surrender to the use of the same, though they are now made devisable by 1 Vic., c. 26, s. 3. Although these estates appear to have many incidents which do not properly belong to villenage tenure or copyhold, not being holden at the will of the lord, or by copy of court roll, and being alienable by deed and admittance thereon, it has been determined that they are not freehold, but that they fall under the same general rules as copyhold estates. (Doe *d.* Reay *v.* Huntington, 4 East, 271.)

TENANT IN FEE-SIMPLE. A tenancy in fee-simple is the greatest estate which a subject can have in land. [Tenure.] The possession of an estate in fee-simple involves a complete power of disposition over the land; and after a grant made in fee-simple the grantor has parted with his whole interest.

The words necessary for transferring an estate in fee-simple may be reduced to this form: 'I give this land to you and your heirs.' (Litt., 1.) The addition of the word 'heirs' is absolutely necessary in a deed, and no other expression will serve; for any such words as 'I give the land to you;' or 'to you for ever;' or 'to you in fee-simple,' would carry to the grantee nothing more than an estate for life. But words of limitation, such as 'heirs,' are not now necessary to pass a fee-simple by devise. (1 Vic., c. 26, s. 28.)

When the tenant in fee-simple dies intestate, the estate descends to the heirs general of the purchaser (in the sense in which that word is explained in 3 & 4 Wm. IV., c. 106), whether male or female, lineal or collateral. [Descent.]

Lands in fee-simple in possession are subject to the courtesy of the husband and the dower of the wife. [Courtesy; Dower.]

Lands in fee-simple in the hands of the heir were subject at common law to the debts of the ancestor due to the crown and to specialty debts. By the 11 Geo. IV. and 1 Wm. IV., c. 47, a complete remedy was given for all kinds of specialty debts, both against the heir and devisee; and by the 3 & 4 Wm. IV., c. 104, estates in fee-simple are made liable in the hands of the heir or devisee for payment of the simple contract debts of the ancestor.

Estates in fee-simple are forfeited to the crown for high treason. (Co. Litt., 390 b.) In cases of petty treason and felony the forfeiture to the crown is only for a year and a day, called the *annus, dies et vastum;* after which time the estate escheats (in cases of petty treason and murder) to the lord. By the 54 Geo. III., c. 145, the forfeiture and escheat consequent upon attainder for felony, except in cases of high treason, petty treason, and murder, are limited to the life-interest of the offender. It would seem that this statute leaves the offender the power of disposing of the estate after his decease. Trust-estates in fee-simple may be forfeited to the crown, but are not liable to escheat.

An estate to a man and his heirs may be given upon conditions or limitations, which are capable of abridging or defeating it. The estate cannot then properly be called a fee-simple; but is, according to the circumstances, a conditional, qualified, or base fee. (Co. Litt., 1 b.)

TENANT IN TAIL. The origin and general nature of estates tail have been already described. [Estate; Remainder; Settlement.]

The estate of the tenant-in-tail has some essential characteristics. He has a right to commit waste of all kinds by felling timber, pulling down houses, opening mines, and doing other like acts; and this right of the tenant-in-tail cannot in any manner be restrained. (11 *Rep.*, 50 a; 3 Mod., 498; 2 Vern., 251.) His estate, being an estate of inheritance, is called a tenant by sufferance: he is one who, though he rightfully entered, continues to occupy wrongfully, as is subject, when it is an estate in possession, to the courtesy of the husband and the dower of the wife. [Courtesy; Dower.] The tenant-in-tail is also entitled to the custody of the title-deeds, which the Court of Chancery will order to be delivered up to him. (2 P. W., 471.) The tenant-in-tail is not bound to pay off incumbrances affecting the fee of the estate, as he has only a particular interest, and not the entire property in the land; and it seems that he is not in general even bound to keep down the interest on such incumbrances; though if he do pay off such incumbrances, it will in general be presumed to have been done in exoneration of the estate. (Cruise, *Digest*, tit. 2, c. 1, s. 40; and tit. 15, c. 4, s. 74.)

By the statute *De Donis* the tenant-in-tail was restrained from alienating his estate in any manner for a longer period than his own life, that is to say, the estate of the alienee, though not *ipso facto* determined by the death of the tenant in tail, became thereupon defeasible by his issue or the remainder-man or reversioner. (2 Ld. Raymond, 779.)

If the tenant-in-tail conveyed his estate by lease and release, covenant to stand seised, or bargain and sale and grant, the right of entry of the issue and remainder-men was not affected by the conveyance. But a feoffment or fine made or levied by the tenant-in-tail in possession by virtue of the entail, caused what was called a discontinuance of the estate tail, whereby the issue and the persons in remainder and reversion lost their rights of entry and were driven to their action. (Litt., 595, 596, 597.) This discontinuance might be either in fee, or for a limited period, according to the duration of the estate created by the conveyance of the tenant-in-tail; but while it lasted it affected not only the estate tail, but all the remainders and reversions. (Litt., 620, 625.) A discontinuance might also be produced by the obligation of a warranty by the tenant-in-tail descending on the person entitled under the entail. This discontinuance however was but partial, extending only to the heirs general of the person who made the warranty. (Co. Litt., 328, 329 a.) A fine duly levied with proclamations was an absolute bar to the issue, though not to the remainder-men, creating what was called a base fee; and by means of a common recovery duly suffered, the tenant-in-tail might bar his issue and all the remainders over, and make an absolute conveyance of the estate. [Recovery.]

By the 3 & 4 Wm. IV., c. 74, fines, recoveries, and warranties of land were abolished, and by the Statute of Limitations (3 & 4 Wm. IV., c. 27) it was enacted 'that no discontinuance or warranty which may happen or be made after that day (31st of December, 1833) shall defeat any right of entry or action for the recovery of land.' It seems therefore that no discontinuance, properly so called, can now be produced by any mode of conveyance, for, whatever may be the form of discontinuance, the last-mentioned statute takes away its effect.

The 3 & 4 Wm. IV., c. 74, which abolished fines and recoveries, has substituted for them certain modes of assurance whereby the tenant in tail may now at once bar his estate tail and all the remainders over. [Fine; Recovery; Settlement.]

In accordance with the principle which prevented a tenant in tail from alienating his estate for more than his own lifetime, leases by tenants in tail might be avoided after their death by the issue in tail. But by the 32 Hen. VIII., c. 28, tenants in tail were enabled to make leases for three lives or twenty-one years, which should bind their issue, though not the persons in remainder or the reversioner.

The estate of the tenant in tail is not subject to any of the debts or incumbrances of his ancestor, except debts due to the crown, by the 32 Hen. VIII., c. 39, s. 75.

Estates tail are subject to the bankrupt laws. The mode of procedure as to bankrupt tenants in tail is regulated by the 3 & 4 Wm. IV., c. 74, the 55th section of which expressly repeals the 6 Geo. IV., c. 16, s. 65, and virtually repeals the 1 & 2 Wm. IV., c. 56, s. 26. The powers of the commissioners of bankrupts as to the disposition of such estates are defined (ss. 56-69).

Estates tail are subject to forfeiture for high treason by the 26 Hen. VIII., c. 13. By attainder for high treason, the estate of the tenant in tail, of his issue, and of all such of his collateral heirs as would have been entitled to take under the estate tail, are forfeited, but not the estates in remainder or the reversion.

The 26 Hen. VIII. extends only to cases of high treason, and therefore as to felonies the statute *De Donis* is still in force, and the forfeiture by attainder for felony extends

only to the life interest of the tenant in tail. (Co. Litt., 302 b.)

TENANT FOR LIFE. Tenancy for life of lands or tenements is the possession of a freehold estate or interest, the duration of which is confined to the life or lives of the tenant or some other person or persons.

The estate of the tenant for life is either (1) such as is created by deed or some other legal assurance, or (2) such as arises by operation of law.

(1) An estate for life may be created by lease with livery of seisin, or by any other conveyance at common law which might be employed in conveying the fee, or by a declaration of a use, or by will. The estate so limited may be either to a person for his own life, or it may be given to one for the life of another, or for any number of lives mentioned in the grant. In the last case, the estate is in effect one for the life of the survivor of the persons so named. On the other hand, an estate may be granted for the joint lives of A and B, in which case it is in fact an estate for the life of the person who dies first.

When lands or tenements are conveyed by deed, without any express limitation of the quantity of estate to be taken by the grantee, he takes an estate for life only. This however is the case only when the grantor might lawfully create such an estate; for if he be tenant in tail, the conveyance, unless it be a lease within the provisions of the stat. 32 Hen. VIII., c. 28, will pass only an estate for the life of the grantor. (Co. Litt., 42 a.) Before the 1 Vic., c. 26, a devise without words of limitation conferred on the devisee a life estate only; but now by sec. 28 of that act, a devise, though without any words of limitation, passes the fee simple, or the whole of such other estate as the testator had power to dispose of, unless a contrary intimation appear by the will.

Formerly, when lands were given to A for the life of B without any words of limitation, if A, or the person to whom he had assigned his estate, happened to die in the lifetime of B, the estate was considered as a kind of *hereditas jacens*, belonging to whoever first took possession; and the person who did so was called the general occupant (Co. Litt., 416). [Occupancy.]

A gift to two persons for their lives is an estate in joint tenancy, and for the life of the survivor, if the parties continue joint tenants; but if the jointure be severed, each has then an estate in the moiety for his own life only. (2 Blackst., *Com.*, 187.)

A condition may be annexed to an estate for life, as well as to an estate in fee simple; but the condition, it appears, must not be one prohibiting alienation on pain of forfeiture, such a condition being considered inconsistent with the nature of the estate. (18 Ves., 433.)

(2) The estates for life arising by operation of law are, the estate tail after possibility of issue extinct, and the estate by courtesy and the estate in dower.

The estate tail after possibility of issue extinct arises when, by the death of one of the persons from whom the inheritable issue is to proceed, it has become impossible that any person should exist upon whom the estate tail can descend. Thus, if lands be given to A and the heirs of his body by B, his wife, or to A and B and the heirs of their bodies, and B die without leaving any issue of their two bodies living, A, from being tenant in tail special, becomes tenant in tail after possibility of issue extinct; which is in effect nothing more than a tenancy for life, with certain peculiar privileges remaining to the tenant out of his former inheritance, the principal of which is the right of committing waste. (Co. Litt., 27, 6; Cruise, *Digest*, tit. 4.)

As to the nature and incidents of tenancy by the courtesy and tenancy in dower, see Courtesy and Dower.

Tenants for life are entitled to estovers; that is to say, to an allowance of necessary wood for the repair of houses and fences on the land; but no tenant for life, except tenant in tail after possibility of issue extinct, can cut down more timber than is necessary for such purposes, or build new houses, or open mines, without being guilty of waste, unless his estate be, as it may be, made expressly without impeachment of waste. [Waste.]

When a tenant for life dies before harvest-time, his executors will be entitled to the crops then growing on the lands, as a return for the labour and expense of cultivation, and these are called in law Emblements. (Co. Litt., 55 b.)

A tenant for life is not bound to pay off the principal of incumbrances affecting the inheritance, but he is bound to keep down the interest of all such incumbrances. (1 Bro. *R.*, 208; 1 Ves. jun., 233; 2 Bro. *R.*, 128.)

In real actions all tenants for life, except tenants in tail after possibility of issue extinct, may pray in aid, or call for the assistance of the person entitled to the inheritance to defend his title, because the tenant for life is not generally supposed to have in his possession the evidences of the title to the inheritance. (Cruise, *Dig.*, t. 3, c. 1, s. 26.) It seems to have been formerly considered that the tenant for life had no right to the custody of the title deeds, but the contrary appears now to be established. (2 P.W., 477; 1. Ves., jun., 72; 1 Sch. and Lef., 209.)

The tenant for life may convey or demise his tenement by the same means as a tenant in fee, provided he does not attempt to convey any estate greater than his own.

If he convey by grant, lease for years, bargain and sale, or lease and release, he can pass no interest greater than that which he himself possesses, the conveyance for the excess is merely void, and no forfeiture is incurred. But a conveyance by feoffment, or by any assurance equivalent to a fine or recovery, if purporting to exceed the bounds of the life estate, displaces the estates in remainder and creates a wrongful fee simple. The person entitled to the next estate in remainder or reversion becomes then immediately entitled to enter, thereby restoring all the estates which had been displaced by the tortious conveyance, except that of the tenant for life, which becomes absolutely forfeited. (Litt., 609, 610, 415, 416.)

As to the merger and surrender of estates for life, see Merger and Surrender.

The name tenant for life is also applied to the person to whom, in settlements or wills of personal property, is given an interest for life only in the fund which is the subject of the settlement or will. [Settlement; Will.]

TENANT FOR YEARS. [Estate; Lease; Term of Years; Tenant and Landlord.]

TENANTS or TENANCY IN COMMON. [Common, Tenancy in.]

TENASSERIM, or TENASSERIM PROVINCES, is a term which has lately come into general use to designate those countries on the west coast of the peninsula without the Ganges which lie on the east side of the Gulf of Martaban, and were acquired by the British by the peace of Yandabo (1826) from the Birmans. At that time the boundaries of this country were very imperfectly known, except that they were washed on the west by the Gulf of Bengal. Even during times of peace predatory incursions had been made both by the Birmans and Siamese, which had the effect of converting large tracts contiguous to the boundary-line into complete deserts, and thus it happened that the limits of the Birmese and Siamese countries were unknown to the two states, which here came into contact with one another, and even up to the present time the British are very imperfectly acquainted with the extent of this possession. A river, Pakeham, constituted, according to old records, the southern boundary-line of Birma in these parts, and the first maps which were published after the peace of Yandabo laid the boundary down near 11° N. lat., but it was afterwards ascertained that the mouth of this river is south of 10° N. lat. and of Cape Victoria. During the occupation of the country by the Birmans, it had been considered that all the country drained by the rivers which fall into the Bay of Bengal belonged to their dominions, and that those whose drainage went to the Gulf of Siam formed a portion of the Siamese empire. When the British took possession of Tenasserim, this watershed was thought to be from 30 to 50 miles from the Bay of Bengal, but it has been ascertained that in some parts it is at a much greater distance, and that between 16° and 17° 40′ N. lat. it is probably 100 miles from the sea. On the map annexed to Snodgrass's Birmese War, the northern boundary is laid down between 18° and 19° N. lat., but it is now known that it is formed by the lower course of the river Thoung Yin, a tributary of the Saluen, and that it does not extend beyond 17° 40′ N. lat. Thus we know that Tenasserim extends from 10° to 17° 40′ N. lat., and it is supposed that the eastern boundary, at least in some parts, approaches 99° 30′ E. long. It is evident that in the present state of our knowledge of the country it is impossible to determine the area of Tenasserim, but we are inclined to think that the

estimate of Dr. Helfer, who assigns to it an extent of 30,000 square miles, is not too great.

The river Saluen or Salween from its confluence with the Thoung Yin to its mouth divides Tenasserim from Birma, and the Thoung Yin divides Tenasserim from the Shan States (Laos) of Zimmay, Laboung, and Yaihang. A range of mountains running from north to south through the whole of the Malay peninsula constitutes the boundary between Siam and Tenasserim as far south as the source of the river Pakcham, and from that point the course of the last-mentioned river forms the boundary to its mouth. In the Gulf of Bengal and opposite to Tenasserim are the Andaman Islands.

Coast and Islands.—The coast of Tenasserim from the mouth of the Salween river on the north (16° 30′ N. lat.) to that of the Pakcham (10° N. lat.), extends in a straight line about 450 miles, and as its bends are not large, nor its inlets wide or deep, its length probably does not exceed 500 miles measured from point to point. A marked difference exists between this coast and that of the opposite coast of Coromandel. The coast of Coromandel extends in a continuous line without a single break, and does not afford a place of refuge even for a small vessel; that of Tenasserim is frequently interrupted by short projecting capes, by which several small harbours are formed, and a few capable of receiving large vessels. The rivers of Coromandel do not admit vessels of any size, on account of the bars at their mouth, but in those of Tenasserim a considerable depth of water covers the muddy bars which lie across their embouchures. No soundings are found along the coast of Coromandel at a distance of seven or eight miles, whilst along that of Tenasserim there are soundings to the distance of 60 or even 80 miles, and though in some places considerable irregularities occur, the changes may be generally said to be tolerably regular, the depth decreasing gradually to ten and even eight fathoms as we approach the land. The coast from Cape Kyekmi or Kiaykami, situated on the west of and close to the town of Amherst, as far south as Tavoy, is of moderate elevation. Between Tavoy and Mergui it is generally low, and in this part it is lined by a rocky reef, on which a great number of small islands rise to a moderate elevation above the sea-level. These islands are known by the collective name of Long Island, and the reef on which they rest, having little water on it, renders the approach of this part of the coast dangerous, and in many places impracticable even for small vessels. South of Mergui the coast-line is broken by several deep inlets, which form large promontories, and enclose some considerable islands. The intricacies on this part of the coast are so numerous, that even at present it has not been completely surveyed, and is laid down rather by guess, though of late much has been done to clear up its position by Capt. Lloyd. This indented coast extends from 12° 30′ to 11° 30′ N. lat. South of the last-mentioned parallel indentations likewise occur, but though numerous, they do not penetrate to a great distance inland. In these parts the country close to the sea is more elevated than at any place farther north, and probably may contain many harbours for small vessels.

Numerous islands occur along the western coast of the peninsula without the Ganges, between 14° 40′ and 8° N. lat. North of 12° they extend to the distance of 70 or 80 miles from the shore, but south of 12° N. lat. they occupy a space of only 30 miles in width. These islands are comprehended under the collective name of the Mergui Archipelago. All the sea between them and the coast of Tenasserim has soundings, though near the islands they are rather too deep for anchorage. These islands also break the swell of the sea during the south-west monsoon, and accordingly the channels which divide them from the main offer great advantages to vessels coasting along this shore, which however have hitherto been little used, because the Mergui Archipelago has only been surveyed within a few years. The islands themselves are rather high, and most of them are visible at the distance of 30 to 40 miles. Without including the islands which occur between 12° 30′ and 11° 30′ N. lat., near the shores, and which are divided by such long and narrow channels from the continent that they are considered as parts of the mainland, the Mergui Archipelago comprehends seven larger and many smaller islands. The larger islands from north to south are Tavoy Island, King's Island, Ross Island, Domel Island, Kisseroing Island, Sullivan's or Lampee Island, and St. Matthew's Island. These seven islands are more than 20 miles long, but vary in width from three to eight or nine miles. They are covered with timber-trees and well provided with water, but all of them have a very rugged and uneven surface, and do not appear to possess great fertility. No part of them seems to be cultivated, and they are only inhabited by a tribe of fishermen, the Seelongs. Two of these islands require notice, on account of their excellent harbours. The northern of these harbours is called King's Island Bay, being formed by the island of this name and Plantain Island, which lies east of it. This harbour is opposite to that of the town of Mergui on the mainland. It can only be entered from the north by large vessels, as the southern portion of the channel, which divides Plantain Island from King's Island has so little depth as to be only passable for country boats. The harbour is spacious and safe, but the entrance has some difficulties, as a shoal extends over a part of it, which has 19 feet of water on the shoalest part at high-water, and only nine feet at low-water. The second harbour is called Elephant Harbour, and occurs at the northern part of the Island of St. Matthew: it is described as very spacious, and capable of containing the largest navy in the world. The soundings vary from 17 to 12, 11, and 10 fathoms nearly close to the shore in some places, and the bottom is soft. It is protected from the sea by several small islands at the entrance, and on the other sides it is sheltered from all winds by the high hills which surround it, so as to be completely land-locked. This harbour was discovered in 1825, by Lieut. Low. The island of St. Matthew is the most elevated of the group; the highest part, situated in the middle, is nearly 3000 feet above the level of the sea.

Mountains.—It is supposed that a continuous range of mountains forms the watershed between the rivers flowing on one side into the Gulf of Siam, and on the other into that of Bengal, and that this range is the boundary-line between Siam and Tenasserim. It is also supposed that the elevation of this range varies between 3000 and 5000 feet above the sea-level, and that the most northern part, which is known among the natives by the name of Thown-gee Mountains, is the most elevated portion. It is stated that in this part it makes a great bend towards the east, forming nearly a segment of a circle. But we have no account of this part of the range: it has only been traversed at the Three Pagodas, which stand near the sources of the upper branches of the river Atta-yen (Attaran); and in reading the account which Dr. Richardson gives of his travels, one would suppose that at this place the summit of the range can hardly be less than 1500 feet above the sea-level: yet he does not say that he traversed it by a mountain-pass. The southern part of the range, when seen from the Gulf of Siam, presents only a succession of peaked mountains, of which some appear to rise to the elevation of 3000 feet. The Siamese give to these mountains with some propriety the name of Sam-roi-yot, which means in their language 'the 300 peaks.' Two roads are said to have formerly been used in crossing this part of the chain; and it is certain that the chain terminates, or rather has a great depression, at the sources and upper course of the river Pakcham. This river runs from north-east to south-west, and is navigable for large boats to Karaa or Pakcham, about 40 miles from its source. To the east of this place runs another river in an opposite direction, which falls into the Gulf of Siam, and is called the river of Choomphon, from the place where it reaches the sea, or Telimfoung, as Dr. Helfer heard it named by the natives. The interval between the navigable parts of these two rivers, occupying a space of about six hours' march, or 30 miles, is a level tract. It is even stated that at high tides the rivers rise so as to inundate this tract, and to mingle their waters; but Dr. Helfer, who visited the place, does not mention this circumstance, and it seems to have been stated on very slender authority. As far as it is known, this chain is chiefly composed of granite and gneiss. These mountains are scarcely ever very precipitous, and are generally rounded near the tops, which rise in gentle declivities. The surface of the rocks is generally decomposed and covered with vegetation; a bare rock is rarely seen. Only a few spots are occasionally cultivated by the Kareans, who are in exclusive possession of these wildernesses.

Surface, Soil, and Rivers.—The general character of the country is hilly, and in some places even mountainous,

but there are also plains of considerable extent and some wide valleys. The degree of fertility which the soil possesses cannot be determined with any certainty, as only a very small portion of it is under cultivation; but we are inclined to adopt the statement of Dr. Helfer, according to which these provinces are much superior in fertility to the Malay Peninsula, by far the greater part of them being really fertile, or capable of being made productive. He thinks that the unproductive, sterile, or unavailable lands are less than one-fourth of the whole; and he ascribes the fertility not only to the natural constituents of the soil, but partly also to the quantity of humus or decayed vegetable matter which has accumulated through centuries, as the whole country is an uninterrupted forest, the greater part of which has never been felled.

The *Northern portion* of Tenasserim we shall call the Region of the Atta-yen (Attaran), as this river drains the most fertile portion of it, and its valley must soon become the centre of a considerable population. This region comprehends the whole of the country as far south as 15° N. lat., or the districts of Amherst and Yee. The most northern districts are mountainous. Along the southern banks of the Thoung-yin, which forms the northern boundary of Tenasserim, runs a mountain-chain, which, as far as it is known, constitutes a continuous ridge. It is called Bo-Thowng, and rises to more than 2000 feet above the sea-level. It is composed of sandstone, limestone, and clay-slate, and its declivities are very steep. In some parts it is overgrown with forests of bamboo. It is not known how this chain is connected with the Thown-gee Mountains, and the upper course of the Thoung-yin river is equally unknown.

The country south of the Bo-Thoung, adjacent to the river Salween, and to the distance of 50 miles from it, for the more inland parts are not known, is a plain, which however contains numerous masses of rocks, composed chiefly of limestone and sandstone. These masses are isolated, but they are disposed in lines running north-north-west and south-south-east. Some of them rise to the height of 2000 feet above the sea-level, but in proceeding southward they sink lower, and on the banks of the Atta-yen they rarely exceed 600 feet. Their structure, especially that of the limestone rocks, is remarkable, as the sides generally are almost perpendicular, and consequently bare, except in a few places, which are not so steep, and where some stunted trees or shrubs grow. No level ground occurs on their top, where they are also quite bare. On their sides there are numerous chasms and caverns. In the southern districts the number of these isolated masses decreases. The tracts of land surrounding their bases are distinguished by fertility, the soil consisting of fine black loam. The remainder of the plain is much less fertile, the soil being composed of an arenaceous clay mixed with a small portion of saline and vegetable matter. The forests which cover the plain contain only trees of moderate size, and there is no underwood.

Within the country just described there is an extensive alluvial tract, which occurs where the three rivers Salween, Gyeng, and Atta-yen join. The principal of these rivers is the Salween or Saluen, generally called by the natives Than-Lweng: it originates in the south-western part of Proper China, in the province of Yun-nan, or farther to the north; for its upper course is not known: in China it is called Noo-kiang and Loo-kiang. Running in a generally southern course, it is supposed to form the boundary between the Shan States (Laos), which are subject to Siam, and the Birman empire. This part of its course is not known. At the mouth of the Thoung-yin it begins to separate Tenasserim from Birma, and this is the only part of its course which has been investigated. Though at this point the river is only about 100 miles from its mouth, and has a great volume of water, it is not navigable. The limestone and sandstone rocks, which are very frequent in these parts, cross the bed of the river, and form several ledges, over which the current rushes with great impetuosity. Near Towng-bio-myo (about 17° 30′ N. lat.) the rapids are so strong as to prevent every kind of navigation except perhaps during the north-east monsoon. There are several other rapids, though less dangerous, farther down, and they cease only at Colon Island (near 17° N. lat.), where the river divides into two channels. The eastern channel alone is navigable. The island is rocky, and about 10 miles long, but only about two miles wide in the widest part. Even below this island the banks of the river are generally bordered by limestone rocks; and the navigation is very dangerous, owing to the force of the current and the numerous eddies produced by the inequalities in the bed of the river, which in these places is extremely deep. A boat once drawn within the vortex of a whirlpool is inevitably lost; both boat and crew are carried down, and never known to make their appearance again.

The Atta-yen or Attaran is known up to the vicinity of its source. Its principal branch originates to the south of the Three Pagodas in the Thown-gee range, and is called Zimee. It flows north or north by west, and is rather a deep river, for even at a short distance from its source it is three feet deep, and this depth increases as it proceeds farther down, where it is joined by numerous small rivers from the Thown-gee range. The current is never rapid, and hence it is used for floating down teak timber. The tide advances to Nat Kyeaung, about 70 miles from the mouth of the Atta-yen. Above Atta-yen, which is more than 30 miles from the mouth of the river, the Zimee is joined by the Way-nio, which comes from the south, and, after the confluence of the two branches, the river is called Atta-yen. This river has a very winding course, and the current is hardly perceptible. As the tide, which here rises to 19 or 20 feet, advances more than 30 miles above the confluence of the Zimee with the Way-nio, it is very probable that the whole fall of the Atta-yen, which amounts to 50 miles, if all its bends are taken into account, does not exceed 12 feet. The river is very deep: in the lower part no bottom is found with 9 fathoms, and up to Atta-yen there is never less than 3 fathoms of water.

The Gyeng or Gain comes from the east, but its upper course is imperfectly known. It is a broad river in its lower course, but is shallow and full of sand-banks.

These three rivers unite nearly at the same place, about 30 miles from the open sea, and by their confluence form a broad sheet of water, which is about 15 miles long from north-east to south-west, and from five to six miles wide, and interspersed with numerous wooded islands. This expanse of waters is separated from the sea by a large island called Phulloo-gewn, or, according to Crawfurd, Balú. This island is about 20 miles long, and 10 in average width. A chain of low sandstone hills runs through its length, never exceeding 200 feet in height. The shores of the island are covered with low mangrove jungle, but it forms only a narrow belt, which is traversed by several creeks that penetrate several miles into the island, and on which behind the mangrove jungle there are plains, which extend to the hills and are covered with rice-fields. The water which is collected above this island finds its way to the sea by two channels, of which the southern runs due south and is about 20 miles long, and called the Martaban river. The navigation of this river is difficult, as the depth of the channel is not more than two or three fathoms at several places, and there are many sand-banks. It does not appear that the channel north of the island of Phulloo-gewn is visited by large vessels.

The country which surrounds the expanse of water into which the three rivers disembogue is interspersed with limestone hills, but the intervening plains are covered with a thick layer of alluvial soil. The banks of the lake and of the rivers are covered with mangroves, and unfit for any agricultural purpose, but at a short distance from the water's edge the alluvial plains are destitute of trees and shrubs, and exhibit a very considerable degree of fertility, producing rich crops of rice where they are cultivated. This rich agricultural tract extends to the confluence of the Zimee and Way-nio rivers.

The country drained by the Zimee is also a plain, which is much higher than that on the Atta-yen river, as the banks of the first-named river rise to 20 feet above its surface, whilst those of the Atta-yen are very low and subject to inundation during the rains. The plains on the Zimee river are nearly a dead level in their lower districts, and no limestone hills occur above the confluence of the two rivers; but in proceeding farther south the surface of the country becomes undulating, and in approaching the Thown-gee range it is broken by numerous deep ravines, though it cannot be called mountainous. This extensive tract is covered with a deep layer of clay of considerable fertility, and the country contains extensive forests, in which the teak-tree grows to a large size. But there are also tracts of less fertility, where the soil is very hard and

intermixed with small nodules of ironstone: such tracts are always overgrown with bamboo jungle, and are the haunts of numerous elephants, rhinoceroses, and other wild animals.

The country between the Atta-yen river and the sea is covered by ridges of sandstone hills about 500 feet high. These hills run in continuous swells as far south as 14° 30′ N. lat. This tract, whose surface is strongly undulating, is of indifferent fertility, owing to the aridity of the soil, which absorbs the moisture. It is chiefly covered with forests, more or less thick according to the depth of the soil. In many places the rocks approach the surface, and have only a thin layer of earth over them, and in such places there are only a few bushes, and patches of grass which soon dry up after the rains. This tract contains two small rivers, which form harbours. The most northern, called Kal-yen, falls into the sea east of the new town of Amherst, of which it constitutes the harbour. On its bar, which is of soft ooze, there are two fathoms and a half of water at low tide; but within the bar, and as far as 8 miles up, it is between five and a half and five fathoms deep; and near its mouth, from 400 to 500 yards wide. It thus forms a spacious harbour, which most merchant ships can enter at low-water neap-tides, and at high-water ships of any burden. Near 15° 12′ is the mouth of the Yee river, which forms a wide æstuary, but it is too shallow to admit large vessels: smaller ships may sail up to the town of Yee, which is about five or six miles from the river's mouth.

The country east of the sandstone tract, and surrounding the river Way-nio and extending to the Atta-yen, is the most sterile part of Tenasserim. The vegetation is stunted, and a great part of this tract is covered with bamboo jungle. The soil is an argillaceous transition schist, unmixed with sandy particles, which quickly absorbs all moisture.

The *Region* of the *Tenasserim River* comprehends the Central portion of the country, extending from 15° to 12° N. lat. The northern districts, as far south as 13° 30′, present a very uneven surface. Several ridges of hills traverse the country from north to south: they consist chiefly of granite and gneiss, and rise to a moderate elevation. They are generally rounded near the tops, and their declivities are rather gentle. The valleys which are inclosed by them are of moderate width, and fertile. The decomposed particles of the adjacent rocks are washed by the rains from the sides of the hills, and deposited at the bottom of the valleys, where they are mixed with a large quantity of decayed vegetable matter, which makes a rich soil. Level tracts of a great extent are rare: the largest are near the town of Tavoy and at the foot of the Thown-gee range, where an elevated table-land occurs, called Meta-mio. The soil of these plains consists of clay or loam, with little sand, and it is very fertile.

The southern districts resemble the northern, except that the hilly ranges, which here also run north and south, occupy a much smaller portion of the surface, the plains being more numerous and of greater extent. The largest are those which occur along the sea-shore, but especially the Plain of Tenasserim, which is many miles in length and several in width, and extends along the left bank of the river above the town of Tenasserim. It is covered with a deposit of argillaceous marl of great depth and fertility. No less fertile is the extensive alluvial tract which surrounds the several branches into which the Tenasserim river divides before it reaches the sea, and which occupies also the greater part of the islands which lie between these branches. A part of this alluvial tract is unfit for cultivation, being inundated at high-water, and covered with mangroves. The whole region is overgrown with forest-trees, with the exception of a few spots which are under cultivation.

The most important river of this region is the Tenasserim. According to Low, it rises near 15° 30′ N. lat., but other known facts render this improbable, and its sources are laid down in our maps south of 15° N. lat. It flows in a southern direction over nearly three degrees of latitude, or more than 200 miles in a straight line. The upper part of its course is interrupted by numerous rapids and falls, which occur even farther down, and as far as 13° 15′, where the last great rapids are. To this place the tides ascend, but the river still has a rapid current, numerous shallows, annually changing banks, and shifting shoals. During the dry season it is impracticable for boats drawing more than 17 inches. It becomes deeper at its confluence with the Little Tenasserim, or Khioung-gale, which joins it at its most southern bend, and brings down a large volume of water from the Sami-roi-yot range. Up to this place, where the town of Tenasserim is built, the river is deep enough for vessels of 100 tons. At the same place the Tenasserim turns to the west, having passed between two high hills to the north-west. Soon afterwards it begins to divide into two arms, which in approaching the sea again subdivide, so that, according to the survey of Captain Lloyd, it reaches the sea by six or seven channels. There are sand-bars across these channels, but the bar which is found on the channel south of the town of Mergui has depth enough for vessels of moderate size at high-water, the tide rising between 14 and 15 feet. Below the town of Tenasserim the river still runs above 40 miles in a straight line. Its whole course is about 240 miles.

The river Tavoy, which originates near 15° N. lat., runs first to the south-west, but turns gradually to the south, so that its lower course is parallel to the shore. The wide æstuary by which it is connected with the sea reaches to 13° 30′ N. lat.; the whole course of the river in a straight line is not less than 100 miles. It is stated that the tide, which rises from 13 to 14 feet, runs up more than 50 miles from the sea, and that to this distance the river may be navigated by boats, though the navigation is rendered difficult by numerous low islands and shoals. The town of Tavoy is about 35 miles from the sea, and so far vessels of 120 tons burden may ascend. There is no bar at the entrance of the river, but the navigation is intricate, owing to the numerous shoals and low islands, as there are various channels among them which in some places have only 2 or 2½ fathoms, but in most parts the depths are from 6 to 12 fathoms. There is good anchorage on the east side of Tavoy Point, which is on the west side of the entrance of the river, in 6 fathoms, on a soft even bottom, and it is well sheltered, except against southern winds.

The *Southern Region* of Tenasserim, or that which lies between 12° and 10° N. lat., is situated on the long isthmus which connects the Malay Peninsula with the main body of Asia, and is known as the Isthmus of Krah. It is the least known part of Tenasserim. Dr. Helfer, who lately investigated its geology and minerals, found it uninhabited, with the exception of a few spots, and from his observations it appears that the whole country is covered with high hills, and contains only a few small valleys. The soil does not appear to be distinguished by fertility, and it may be conjectured, that with the Isthmus of Krah that sterile tract begins which extends over the whole of the Malay Peninsula to its most southern extremity, and which, though favourable to the growth of fruit-trees, produces only scanty crops of rice and other grain. The inhabited places of this tract are almost exclusively confined to the banks of rivers, and do not extend far inland. The rivers, though they have not a long course, are said to be large and navigable to a considerable distance from their mouths. The largest are, from north to south, the Lenya, the Bockpyn, and the Pakeham. The last-mentioned river, which divides Tenasserim from Siam, has already been noticed.

Climate.—Like all other intertropical countries, Tenasserim has only two seasons, the dry and the wet season. They depend on the monsoons, the rains being produced by the south-west monsoon, whilst the dry season lasts during the north-east monsoon. There appears to be some difference in the wet season between the climate of Maulmain and of Mergui, the only two places in which a few meteorological observations have been made, and this difference appears to depend on the circumstance, that along the southern coast the effects of the south-west monsoon are diminished by the elevated islands of the Mergui Archipelago, whilst farther north they reach the land in all their force. At Maulmain the rainy season sets in towards the end of May or the beginning of June, and during the first three months the rains are heavy and nearly incessant, but they gradually diminish in September, and entirely cease in October. This is the hottest part of the year, but the heat is far from being so oppressive as on the coast of Coromandel. In May the thermometer averages at 8 o'clock in the morning 78°, and at 4 o'clock in the afternoon 82°, in June it keeps at 72° at 8 o'clock, and at 76° at 4 o'clock, and in July and August at 77° at 8 o'clock, and at 80° at 4 o'clock. The thermometer has never been observed to rise above 90°. The difference

between the temperature of the air in the day and at night is remarkable, as the thermometer is often found at 65° at sun-rise, even in July. In the dry season the thermometer varies between 60° and 80°, and the weather is very constant, rain rarely falling, and only in short showers. The heat is moderated by the sea and land breezes, which blow very regularly in this season.

At Mergui the rainy season sets in towards the end of April or the beginning of May, and lasts to the month of November. During the first two months the rains are moderate, but from the middle of June to the beginning of September they are heavy, when they again begin to abate, and gradually to diminish. Rain falls also during the dry season, but only in showers, which occur at intervals from four to six weeks. The greatest heat occurs before the rains, and in the first two months after they have set in, but it is stated that the average temperature of the six hottest months does not exceed 84°. Land and sea breezes are regular during the dry season. At some places in the interior, which are considerably elevated above the sea, as the table-land of Meta-mio, the climate is some degrees more temperate than near the coast.

The climate is considered very healthy. This opinion is confirmed by Dr. Helfer, who lived there many years, and who says that it is the most healthy of all known tropical countries for Europeans; and he supports his opinion by the statement that the lists of mortality kept by the medical gentlemen of the European British corps stationed at Maulmain and its dependencies show that the rate of mortality scarcely ever exceeds and is sometimes less than it would be under similar circumstances in Europe. This is the more remarkable, as many of the adjacent countries, and especially Aracan, which resembles Tenasserim in nearly every respect, have acquired a bad name for their insalubrity. Helfer cannot account satisfactorily for this phenomenon. He finds no other reason than that the country is either part of a narrow peninsula or immediately adjacent to one, and that the extensive seas on both sides produce a constant though not always perceptible current of air, by which the noxious vapours that rise from vegetable matter and other elements of malaria are either destroyed or carried away. Even the exposure to the sun is rarely attended by bad effects, and the climate does not produce languor or mental inactivity, which is partly to be attributed to the coolness of the nights.

Productions.—If the value of a country were to be estimated by the number of marketable articles exported from it, Tenasserim would certainly be one of the least valuable. For, if a small quantity of rice and some teak timber are excepted, hardly any article worth mention has been exported from that country up to the last few years. But it vies with any country on the globe in the varieties of its natural products, and when cultivated it will export almost every article which belongs to tropical countries.

Though the greater part of the country has not been explored, it is known to be rich in minerals. Gold is found in some of the rivers, but in small quantities. A silver-mine exists in the range of the Bo-Thowng, but its value is still doubtful. It has lately been ascertained that there is copper-ore in the north-east portion of Sullivan's Island, and on the island of Calla-gkiank, near Mergui. Tin is the only metal which has ever been worked. The tin-mines are about one day's journey to the east of the town of Tavoy, and in the vicinity of Mergui. But Dr. Helfer, who has explored the southern districts, states that the range of hills which runs north of the Pakeham River is the richest in tin-ores, the grains or crystals being sometimes of the size of a pigeon's egg, and the layer in which they are found being 8 or 10 feet thick. It is however difficult to work these ores, as the contiguous country is entirely uninhabited. Tin-ore is also found on the banks of the Bokpyn river and on Domel Island. The richest deposits of tin-ore are probably yet unknown. Iron-ore of good quality is found in abundance in the vicinity of Tavoy, and at several other places farther south, especially in the districts south of the Tenasserim river. Antimony occurs in the neighbourhood of Maulmain. Extensive coal-measures have been lately discovered in several places on the banks of the Tenasserim river. The coal is generally of good quality, and the best kind is near the banks of the river below the last rapids, so that it can be brought to Mergui at moderate expense. Three or four years ago this mine began to be worked at the expense of the East India Company. It is thought that the discovery of these coal-measures will have some effect on the steam-navigation of the Gulf of Bengal and the Straits of Malacca. Limestone and marble are common in the northern districts.

Rice constitutes the principal object of cultivation: but it does not appear that irrigation is practised; and only one crop is taken. Wheat is cultivated at a few places on a small scale. Other objects of agriculture are sesamum, chilies, yams, sweet potatoes, plantains, and melons. The sugar-cane, indigo, and tobacco are only grown for home consumption, and also cotton, which is of an inferior kind. It is thought that these last articles could be raised to a great extent if there was a demand for them. Among the trees which are cultivated the most important is the areca palm, which succeeds well as far north as 15° N. lat. Since the occupation by the British, the natives have begun to cultivate it on an extensive scale, and it will soon yield a large article of export if the fruits of this palm should continue to be used in Europe for tanning, instead of oak-bark and sumach. Of late years coffee-trees, nutmeg-trees, and clove-trees have been introduced. The first two thrive well, and promise to remunerate the cultivators, but the success of the clove-trees is still doubtful. The produce of the coffee-trees is compared with the second quality of Java. Nearly all the delicious fruits which grow in the Malay Peninsula and the Indian Archipelago may be raised in Tenasserim. The durian is found up to 16° N. lat., and is exported to Rangoon and other places of Ava. The mangosteen has lately been introduced, and thrives well, but only south of 13° N. lat.; mangoes, pine-apples, guavas, and oranges also succeed well. In some parts the arnotto (Bixa orellana) is raised. Cocoa-nut plantations are rather extensive near the sea, and also the nipah palm (Nipa fruticans). The toddy or palm-wine of the latter contains more saccharine matter than the cane. Nearly the whole of Tenasserim is covered with timber-trees, which are not much used at present; but as the countries surrounding the Bay of Bengal are mostly destitute of such forests, and the demand for timber is rapidly increasing, they will soon be considered as a source of wealth. Extensive forests of teak-trees still exist on the banks of the Attayen, and furnish at present the most important article of export. A small number of junks are annually built by Chinese at Mergui and Tavoy from the Hopea odorata, which is also employed by the Birmese in the construction of small craft. The best timber-trees, except the teak, belong to the Hopeas, Vaticas, and Shoreas; the most numerous are the Dipterocarpeæ, which attain an enormous size, but furnish an inferior wood. All these trees when full grown are from 70 to 120 feet in height, rising with a straight trunk 40 or 60 feet high, and before they throw out any branches they have a circumference of 10 to 30 feet. In addition to timber, the natural productions which are derived from the forests and plants which grow wild are numerous. There are various kinds of trees yielding caoutchouc, sticklac, gamboge, sassafras, cajeput-oil, different gum-resins, nut-oil, black varnish, sandal-wood, dammar, several tanning substances, several dyes, aloes, and sapan-wood. Cardamum-plants are said to be found in the mountains on the eastern boundary, and hemp grows wild on some of the river islands. Large tracts are covered with bamboo-jungle, and bamboo begins to be exported, having been found of a superior quality to that grown in the neighbouring countries. On the Sam-roi-yot range there is an aromatic wood, called by the natives callame, which is brought down to Mergui, and there shipped for Rangoon.

Domestic animals are not numerous, with the exception of buffaloes, which are large. As to wild animals, Helfer observes that as Tenasserim constitutes as it were the bridge by which the continent of Asia is united to the Indian Archipelago, its zoology possesses several species peculiar to these two great natural divisions of Southern Asia. The number of species common to Bengal and Hindustan is comparatively small, but in the northern districts of Tenasserim there are many species which are peculiar to the countries east of the Brahmapootra, and even several of Bootan and Nepaul; and in the southern, others which have hitherto been exclusively found in the Indian Archipelago.

There are five different kinds of quadrumana: a species of cercopithecus belongs to the rarest animals of this class;

it is chiefly found in the northern districts, on the isolated limestone rocks. The Malay bear occurs in the more mountainous parts as far north as 13° N. lat. The royal tiger is found in great numbers, and is very strong and large; but it is said that it rarely attacks men. The black tiger is common. There are also leopards and wild-cats. Elephants are numerous, and they have a wide extent of forests to range in. They are killed and eaten by the natives, who bring their teeth to Maulmain. The rhinoceros is very common, and all the known Asiatic species are found. The Malay tapir, called by the natives the 'great pig,' is found in the most southern districts. The wild hog is common, and also the Sus Babiroussa. The Cervidæ are numerous: Rusa Hippelaphus, Elaphus Wallichii, Cervus Aristotelis, C. Axis, and C. Muntjac, with two other species, are known to exist. The Bubulus Arni and Domesticus are both in a wild state; and of the Bisons, the great Gaurus is rather rare, but Bison gayal is very common. A variety of Cinnyris, and Nectarinia, in its splendid plumage and diminutive size, resembles the humming-birds. Four species of Merops rival in colours the species of Java and Australia. The Indian peacock is abundant in the interior near mountain-torrents. There are five species of parrots. The Phasianus gallus, the origin of our domestic fowl, is very common in the jungle, and the native breed is kept up by supplies of eggs from the forests. The Hirundo esculenta inhabits the cliffs along the southern coast and the islands of the Mergui Archipelago, and a considerable number of the nests are annually collected and exported by the Chinese. There are several species of hawks, falcons, and herons, and five kinds of pigeons, some of which are very beautiful. Fish is abundant between the islands of the Mergui Archipelago, where an extensive fishery is carried on by the Seelongs, Malays, and Chinese, who prepare fish for market, which is done by spreading it over a framework of mangrove-trees, and drying it in the sun: it is also daily trodden with the feet twice. No salt is ever employed in curing the fish: some kinds of fish are smoked. In these parts there are also shrimps, prawns, &c., of which balachong, or pressed fish, is made, which is an article of commerce. Whales are frequently seen among the islands of the archipelago, and a little oil is got. There are also some pearl-banks, which were formerly fished, but an attempt made for that purpose some years ago was not successful. Trepang is one of the principal objects of fishery. Tortoise-shells, mother-of-pearl, and ambergris are collected in small quantities by the Seelongs. Wax and honey constitute an important article of internal commerce, and are partly also exported. There are said to be five different species of wild bees, two of which are without stings. Snakes are numerous, but only a few kinds are poisonous.

Inhabitants.—Helfer estimates the population of Tenasserim at about 100,000 individuals, and consequently there are about three to a square mile. Though this population is very small, it consists of very different races, or rather we find different races mixed. This is chiefly to be ascribed to the frequent conquests to which the country has been subjected since the time when it was first visited by Europeans. In the last two centuries the Siamese, Thalians, and Burmese have alternately and more than once possessed Tenasserim. These nations appear to have adopted a policy which we find mentioned in the most antient historical records of Western Asia, namely, the transplanting of the inhabitants of one country to another at a great distance from it.

The bulk of the population consists of Birmans, Thalians or Thalains, Siamese, and Karians or Karens. Though all these nations have some physical features which belong to the Mongol race, yet there are others which indicate that a mixture with other races has taken place. The Siamese approach nearest to the Chinese: they have a flat forehead, a small nose, prominent cheek-bones, black hair, very thin beards, thin lips, and a colour more or less yellow. The Birmans and Thalians are half Malays and half Chinese, and the Karians half Malays and half Caucasians; indeed the features of the Karians approach so much to the Caucasian form, that many of them have aquiline noses, a high forehead, and the European facial angle. This resemblance to the Caucasian race seems one of the reasons which has led some American Baptist missionaries to consider the Karians as the lost tribes of Israel.

The Birmans, who were the lords of the country up to the peace of Yandabo, are still the most numerous. They are settled in the plains on the rivers Atta-yen and Gyeng, in the vicinity of Mergui, Tavoy, and Yee, either near the sea-coast or on the banks of navigable rivers or creeks, and never far inland. They are healthy, strong, and muscular. Their principal occupation is agriculture. They are indolent and self-conceited; but honest, polite in their manners, and neither passionate nor revengeful, by which they are distinguished from the Malays. They are Buddhists, and consider the sovereign of Ava as the head of their religion: they are quiet subjects. The children are placed at an early age in monasteries, established in almost every village, and endowed by the voluntary contributions of the inhabitants: the children remain here for a certain time, during which they are fed by the monks, and instructed in reading, writing, and religion; and thus elementary knowledge is more generally diffused among the lower classes than in most countries of Europe; but the knowledge of the higher classes is not much greater. The knowledge of their priests is limited to the explanation of theological and metaphysical doctrines. The missionaries have hitherto failed in their attempts to convert them to Christianity, with the exception of a few isolated instances, where Birmans have nominally become Christians for the sake of worldly gain. This want of success is not to be ascribed to fanaticism or obstinacy on the side of the Birmans, but to their religious dogmatical indifference. They admit the beauty of the Christian morals, but contend that theirs are equally good; and with reference to the dogmas, they say that the Christian are as unintelligible as the Buddhist.

The Thalians or Peguans do not differ in physical constitution from the Birmans, and their separation into two nations might be considered merely a political one, as they had formerly two different governments, if it were not that the Thalians speak a different language, which is said to have scarcely any resemblance to that of the Birmans. But this language is fast declining, as the greater number of the Thalians speak the Birman language, which has been adopted as the language of the courts, of public transactions, and of general conversation. The Thalians are likewise Buddhists, and participate in the education provided by that religious establishment. Their chief and almost sole occupation is agriculture, and rice is almost the only object of cultivation. A small number of Thalians were settled on the Atta-yen previous to the occupation of Tenasserim by the British, but a much greater number have emigrated since that event. Having shown during the war a great partiality for the British, they feared the vengeance of the Birmans when their country (Pegu) was restored to that nation, and took refuge in Tenasserim, where they settled in the vicinity of the new settlement of Maulmain, where there are at present twenty Thalians for one Birman.

When Tenasserim was subject to the king of Siam, the Siamese were very numerous, but after their conquest by Alompra they retired from these provinces almost entirely, except the districts south of Mergui, where a number of them remained on the banks of the rivers Lenya and Bokpyn, that part of the country having always remained a disputed district. The security and equitable administration introduced by the British have attracted a considerable number of emigrants from Siam, who have formed settlements in several parts of the country, especially on the banks of the Greater and Lesser Tenasserim rivers. They are, according to Helfer, an industrious, hardy race, and more enterprising than the Birmans, besides being quiet, obedient, and orderly. He thinks that their immigration in greater numbers would be a desirable accession in the wilds of Tenasserim. They have introduced the cultivation of the sugar-cane for the purpose of making sugar, which art they have learned from the Chinese who are settled in their country, though this cultivation has not yet become important. Many of the Siamese are huntsmen by profession, living for months in the wildest forests, where they shoot elephants for the ivory; they are also the trappers, tamers, and managers of elephants in general. Under the Birman rule few elephants were tamed, but at present the practice is becoming more general through the Siamese, in whose country elephants are the most important of domestic animals.

The Karians occupy exclusively the country adjacent to the mountain-range which divides Tenasserim from Siam,

never being found near the sea-shore. They are said to be the same nation which occupies several mountain-tracts in Birma, and is dispersed over the delta of the Irawaddi [Birma, vol. iv., p. 440], and to support this opinion it is affirmed that the Birman Karians bordering upon China, at the distance of 13 degrees of latitude, speak a dialect of the same language which is current among the Karians of Tenasserim. This fact requires to be confirmed, for in other respects these nations differ greatly in habits. In Birma the Karians are the most industrious cultivators of the soil, and manufacture several kinds of cotton and silk cloth, but those of Tenasserim are an agricultural people without any fixed habitations, migrating every second or third year. When a Karian family has chosen a place for a plantation, huts of bamboo thatched with palm-leaves are constructed, and a part of the forest is cleared, just as much as is necessary to plant the ground with rice sufficient to maintain the settlers for a year. The paddy is sown upon the ground, which is imperfectly cleared, without any tillage or other preparation, and whatever else is wanted (cotton, indigo, sesamum, vegetables, &c.) is sown or planted promiscuously on the same spot. The following year another spot is cleared in the vicinity, and after some years, or when a death happens, the family removes to a greater distance, and begins again the laborious task of felling immense forest-trees, visiting only from time to time the old establishment, which yet yields fruit for several seasons, and thus the Karian wanders all his lifetime without ever settling permanently. It seems however that an improvement in the condition of the Karians is taking place. Their religion is heathenism. They believe in evil spirits, called nâts, which have a direct influence on the destinies of mankind, and they try to propitiate them by sacrifices of fowls, tobacco, rice, and pieces of money, which they deposit at certain places. The attempts to convert them to Christianity by the American missionaries have been successful. A tribe of the Karians, called the Red Karians, inhabit the mountains north-east of Maulmain, and these mountaineers are said to live by robbery.

The Seelongs are the lowest in civilization among the nations of Tenasserim. They are confined to the islands of the Mergui Archipelago, and are a race of wandering fishermen, who build temporary huts of reeds, palm-trees, and bamboos, during the inclemency of the monsoon, and pass the rest of the year either in boats or on the sea-beach under the shade of trees. They never cultivate the ground, but live upon the spontaneous products, chiefly turtles, fish, and shell-fish, which form their principal food. They have a peculiar language, but too little is known of it for us to determine whether it is a mixture of languages or a peculiar tongue. They form a petty tribe, not exceeding, it is said, 1000 souls in number, and it is very difficult to meet them in the islands which they visit, as they hide themselves whenever they see a strange sail approaching. This is probably the effect of their having suffered much from the pirates, who, until lately, infested those seas, and it serves to explain the statement of the early European navigators, who landed on these islands, and found them uninhabited. The Seelongs have a vague idea that there are certain invisible beings which exercise an influence over the destinies of mankind, but there is no established mode of worship, and they are entirely ignorant of a future state. No attempt has yet been made to convert them.

Helfer reports, that among the natives the opinion is general that in the most mountainous part of the country there is a race of wild men, who shun all intercourse with their neighbours, and seem to be hardly superior to monkeys. He is much inclined to think that these wild men are the gigantic orang-outang of Sumatra. But the Andaman Islands are inhabited by a puny race of men, the lowest in the scale of intellectual beings, which seems to belong to the race of the Australian negroes; and only a few degrees farther south, in the kingdom of Queda, a small tribe, the Samnng, are found [Malay Peninsula, vol. xiv., p. 327], who greatly resemble the inhabitants of the Andaman Islands. It is therefore not improbable that a small remnant of such a tribe may still exist in Tenasserim.

The Karians, Seelongs, and the last-mentioned race are probably aborigines: the others have emigrated from the neighbouring country. Many Chinese are settled in the sea-ports, where they are merchants, ship-owners, ship-builders, spirit-distillers, carpenters, blacksmiths, bakers, and gardeners. A few of them settled when the country was subject to Birma, and others have come since the occupation by the British. They are married to Birman women, but their children, if males, are brought up as Chinese, and adopt the customs, manners, and dress of their fathers. There are also a number of Chuliahs, or natives of Coromandel, settled in the places where Europeans reside, with whose customs and wants they are much better acquainted than the natives, and by administering to which they gain their livelihood. The same may be said of the Bengalees, who however are always inferior to the people of the peninsula of Hindustan in enterprise and capacity. Their number is not great. As Tenasserim is the penal settlement for the British possessions in Hindustan, about 2000 convicts have been sent there, especially Thugs. They are treated with great mildness, and most of them have been converted into useful members of society. Many of them have married, and on the term of their banishment expiring have settled in the country. At Maulmain a few Armenians and Parsees are settled, this being the only place in Tenasserim where trade is carried on.

The English settled in Tenasserim are almost all in official capacities, either civil officers of government or the military officers of the two regiments which are stationed here. The number of private persons is small, and almost all of them are congregated in Maulmain, where they are chiefly engaged in ship-building, or otherwise connected with the teak-timber trade. Besides a few American Baptist Missionaries, there are many descendants of Portuguese. By intermarrying with native women, they have partly lost the advantages of European civilization, their condition being nearly the same with that of the natives, and frequently much lower. Their steadiness in adhering strictly to their faith preserves them as a distinct class. They have also mostly preserved their language, but it is barbarously corrupted.

Towns.—In a country so little cultivated, and the population of which is dispersed over such an extent, there can be no large towns. When the British took possession of the country they founded the town of Amherst, near the mouth of the Martaban river, hoping that the commerce of the country would concentrate at this place. [Amherst, vol. i., p. 452.] But these expectations have not been answered. Maulmain, which was at first only a military post, has since risen into importance and is rapidly increasing, as its situation near the confluence of the Attayen with the Salween is the most favourable place for carrying on the trade in teak, which constitutes the most important article of export. Ship-building is the only trade which is carried on to any extent. The town of Tavoy is also small, but it has some commerce with Rangoon and Mergui. The town of Mergui has the advantage of a safe and well-protected harbour. The roadstead is between the mainland and Madramacan Island, with a soft bottom in from 6 to 15 fathoms, and large vessels are sheltered from all winds. It is about six miles from the town. But vessels of moderate size can go over the bar into the river, and anchor off the town in five fathoms. Though it is at present a small place, it will probably rise to great importance, as in the country at the back of it the richest deposits of coal and tin have been discovered. The neighbourhood is also particularly well adapted for plantations of spice-trees, and the Siamese have begun to cultivate the cane for making sugar: it is also well situated for commercial intercourse overland with Bangkok and the countries of Siam which surround the gulf of that name. Tenasserim, an antient town, which however was destroyed in the wars between the Siamese and Birmans, is in ruins, but will probably be revived, owing to the coals in the neighbourhood and the sloop navigation extending to this place.

Manufactures and Commerce.—If we except the building of vessels and small craft at Mergui, Tavoy, and especially Maulmain, there is no manufacturing industry in Tenasserim; nearly the whole population is in that stage of civilization in which it has not yet acquired a taste for refinement and comforts, and articles of foreign manufacture are not much in demand. Such articles as cotton-cloth, coarse china-ware, and iron cooking-vessels, are brought by the Chinese from Bangkok, and cotton-cloth, gunpowder, and arms imported from England by way of Penang or Calcutta. There are also imported petroleum

and tobacco from Rangoon, and spices and sugar from Penang. The chief exports are teak and rice; there are also exported ivory, wax, tin, nut-oil, trepang, edible birds' nests, and bamboos. The only places with which a commercial intercourse exists are Calcutta, Rangoon, and Penang. It is hoped that an overland commerce will soon be established between Maulmain and the south-western provinces of China, especially Yun-nan, as caravans from those parts annually visit the Shan States (Laos) north of Tenasserim, and the merchants of the caravans manifested a few years ago an intention to proceed to Maulmain, but were prevented by political circumstances.

History.—Nothing is known of the early history of these provinces. When they were first visited by the Portuguese, several places were much more thriving than they now are. It seems that at that time the bulk of the population consisted of Thalians, and probably the country formed a portion of the kingdom of Pegu. It was afterwards connected with Siam, from which it was wrested by Alompra, the founder of the present Birman dynasty, about the middle of the last century. Notwithstanding the repeated contests and incursions of the Siamese, it remained a part of the Birman empire until it passed into the hands of the British by the peace of Yandabo (1826). At that time the population was estimated at 50,000 individuals: at present it probably considerably exceeds 100,000. It forms part of the government of Penang.

TENBURY. [Worcestershire.]

TENBY. [Pembrokeshire.]

TENCH, a fresh-water fish belonging to the family *Cyprinidæ*, or Carp tribe. [Tinca.]

TENDER. A tender is the offer to perform some act. In practice it generally consists in an offer to pay money on behalf of a party indebted, or who has done some injury, to the creditor, or to the party injured.

A tender to the amount of forty shillings may be made in silver; but beyond that amount it must be in gold. If a tender be made of a larger amount in silver, or in bank-notes, and no objection be taken at the time to the medium in which it is made, the objection to the tender on that ground will be held to be waived, and the tender will be held good to the full amount to which it is made. The money tendered must be actually produced and shown, or at least the bag or other thing which contains it shown to the party to whom it is intended to be made, unless it is dispensed with by some declaration or act by the creditor. This is insisted upon with such strictness, that even though a party tell his creditor that he is about to pay him so much, and put his hand into his pocket to produce the money, yet if the creditor leave the presence of the debtor before the money is actually produced, no tender will have been made: but if the creditor refuse to receive the money mentioned on the ground that it is insufficient in amount, the actual production of it is not necessary to constitute a valid tender. The offer must be absolute and without conditions. An offer of a larger amount with a request of change; an offer with a request of a receipt, or on condition that some thing shall be done on the part of the creditor, are not valid tenders; but an offer of a larger sum absolutely without a demand of change is good. A tender may be made either to the party actually entitled to receive it, or to an agent or servant authorised to receive it, or to a managing clerk; and a tender will not be invalidated even though before it is made the creditor has put the matter into the hands of his attorney and the managing clerk of the creditor refuses to receive it, assigning that circumstance as his reason for doing so. If the attorney write to the debtor demanding the money, a tender afterwards made to him or to his managing clerk is good, unless at the time when it is made they disclaim authority to receive the money. A tender ought to be made on behalf of the party from whom the money is due; but if the agent appointed by him to make the tender offer a larger sum than he is authorized to do, the tender will nevertheless be good for the full amount to which the tender is made.

If the defendant in an action plead a tender, he must state that he has always been ready to pay the money, and he must also pay it into court. The effect of the plea is to admit the existence of the contract or other facts stated in the declaration which form the cause of action in the plaintiff. The plea goes only in bar of damages. The plaintiff therefore in such case can never be nonsuited: but if issue is taken on the mere fact whether or not the tender has been made, and that fact is found for the defendant, it is a good defence to the action.

By various statutes, magistrates, officers of excise, &c. are empowered after notice of action to be brought against them, to tender amends; and if the amount tendered is sufficient, the tender is a defence to the action.

TENDON, or Sinew, is the tough white and shining tissue by which muscles are attached to the bones or other parts which it is their office to move. The name of tendons however is generally applied only to those which are thick and rounded, and which serve for the attachment of the long round muscles, such as those of the biceps muscle on the front of the upper arm: those which are broad and flat, and which serve for the attachment of the membranous muscles, are commonly called aponeuroses. But whatever be the external form of a tendon, its intimate construction is the same, being chiefly composed of the same fibrous or tendinous tissue of which a large class of organs, including the ligaments, fasciæ, periosteum, and several others, consist.

The fibrous or tendinous tissue is of a peculiarly glistening bluish-white colour, dense and tough, nearly insensible, not vitally-contractile, and very little elastic. It is composed of bundles of delicate fibres, which are united by cellular tissue; and each fibre is made up of several fibrillæ, or filaments, which are discernible only with the microscope. The filaments are transparent and cylindrical, with well-defined outlines: they vary in diameter from $\frac{1}{30000}$ to $\frac{1}{10000}$ of an inch, and, though they have a generally straight direction, are finely undulated. The tendinous fibres are from $\frac{1}{7500}$ to $\frac{1}{3750}$ of an inch in diameter; the filaments are arranged within them in parallel lines, and are connected by a firm substance, in which no distinct structure can be discerned. The bundles of the fibres are arranged in various plans in the different tendons and aponeuroses: in some, they are parallel; in some, interlaced or variously woven together; but their arrangement is always such that they possess the greatest force of resistance in the direction in which the muscle acts upon them.

The tendons, like the other fibrous tissues, are composed of a substance slowly yielding gelatine by boiling. A large quantity of the ordinary glue of commerce is obtained by boiling down the tendons and ligaments about the feet of horses. They contain about 60 per cent. of water; and when dry become hard, brittle, yellow, and transparent. In vital properties they are distinguished by a very low degree of sensibility. No pain is excited by the application of stimuli; but when stretched or twisted, the dull aching pain is produced, with which most persons are acquainted as characteristic of a sprain. Their diseases are few and are peculiarly slow in their progress.

The chief differences of appearance in the tendons depend on the quantity of cellular tissue interposed between the bundles of tendinous fibres. In the round tendons there is so little, that it is with difficulty demonstrated, and they are, in a corresponding degree, compact and strong. In the flat membranous aponeuroses the cellular tissue is much more abundant, and fills up large interspaces between the fibrous bundles. The more abundant the cellular tissue, the more numerous do the blood-vessels of the tendons seem to be. In the round compact tendons they are scarcely discernible; but when well prepared, the same arrangement is observed in them as in the blood-vessels of all the fibrous tissues; that is, they run in parallel lines between the fibrous bundles, rarely dividing into smaller branches, and communicating by short canals which pass transversely across the bundles. The blood-vessels of the tendon are chiefly derived from those of the muscle to which it is attached. In most instances a large branch runs across the line of boundary between the muscular and tendinous fibres, and gives off many smaller branches to the latter.

At that end of a tendon which is affixed to a muscle each primitive fibre or fasciculus of the latter [MUSCLE] terminates in an abruptly-rounded extremity, which is embraced by a fasciculus of the filaments of the tendon, expanding and enclosing it in a sheath, or in a manner which may be coarsely represented by placing the end of the fore finger of one hand within a circle formed by the ends of all the fingers of the other hand. The larger bundles of cellular and fibrous tissue in the tendon are also continuous with the cellular tissue which is placed between the secondary fasciculi of the muscle.

At their opposite extremities the tendons are usually affixed to bones. Their fibres are intermixed and firmly united with those of the periosteum, and often pass into the very substance of the bone.

Although the chief and proper office of tendons is to serve as media for the action of muscles, yet many of them fulfil other purposes in the economy. Thus the aponeuroses of the abdominal muscles form a great part of the walls of the abdomen, and, by their toughness, support and protect the organs within its cavity; the tendons of the muscles of the fingers add strength to each joint over which they pass; and many, in other parts, are arranged so as to act like ligaments.

TENDRAC. [TENREC.]

TENDRILS, or *Cirrhi*, are those elongated and filamentous organs of plants which possess a power of twisting in one direction or another, and by which the plants on which they grow are enabled to embrace other plants, and thus to elevate themselves. Tendrils are only found on those plants which are too weak in the stem to enable them to grow erect. In most cases the tendrils are only forms of the petiole; for although they may occur on the parts of flowers, yet the flowers must be regarded as metamorphoses of the leaf. Tendrils are distinguished according to the parts of the leaf from which they grow. When the tendril consists of the elongated petiole of a compound leaf, it is called a *cirrhus petiolaris*, as in the common pea. When, as in Smilax horrida, it branches off on each side at the base of the lamina into a twisting branch, it is called a *cirrhus pedunculares*. When it is extended from the point of a single leaf, as in the Gloriosa superba, it is a *cirrhus foliaris*; and when it occurs in the petals of a flower, as in Strophanthus, it is called *cirrhus corollaris*. Those tendrils which are in connection with the stem alone, as those of the passion-flowers and vines, are called *Capreoli*. The type of these organs however is the same in all cases. (Bischoff, *Wörterbuch der beschreibenden Botanik*.)

TENEDOS (Τένεδος), an island in the Greek Archipelago, off the coast of Troas, in 39° 47′ to 51′ N. lat. and 25° 58′ to 26° 5′ E. long. It is said to have been anciently called Leucophrys, and to have derived the name Tenedos from Tennes, the son of Cycnus, king of Colone in Troas, who reigned over the inhabitants, and was afterwards deified by them. (Pausanias, x. 14; Schol. in Hom. *Il.*, i. 37; and more fully Diodor., v. 83.) According to Homer (*Il.*, xi. 624), it was sacked by Achilles, and occupied by the Greeks when they retired from the siege of Troy immediately before its capture. (Virg., *Æn.*, ii. 21.) This connection with the story of the Trojan war has given Tenedos some celebrity. It was colonized by Æolians from Amyclæ in Laconia, under the command of Peisander and Orestes. (Pindar, *Nem.*, xi. 45-6; Herod., i. 151.) Little mention is made of Tenedos in antient history. It was independent in the time of Cyrus, king of Persia, but was made subject to Persia after the revolt of Ionia in the time of Darius (B.C. 493): it was afterwards a tributary of Athens, and in the fourth year of the Peloponnesian war took part with the people of Methymna against the rest of the Lesbians. (Thucy., iii. 2.) Pausanias states that the Tenedians, becoming unable to defend themselves, submitted at some period of their history to Alexandria in Troas. Aristotle (*Rhet.*, i. 16) mentions some dispute as having recently occurred between them and the Sigeians, in which they cited in support of their cause the writings of Periander of Corinth. According to Cicero, Verres robbed the Tenedians of a statue of Tennes, their founder, of most beautiful workmanship. (*In Verrem*, i. 19.) Pindar (*Nem.*, xi.) speaks of the Prytanes, or yearly magistrates of Tenedos, to one of whom, Aristagoras, he addresses this ode. It appears from Stephanus Byzantinus that Aristotle wrote on the constitution of Tenedos. On the antient silver coins of the island are the types of a double-edged axe of a peculiar form; and on the reverse a bifacial head like that of Janus. The 'Tenedica securis' (axe of Tenedos) was a proverb expressing any summary mode of executing justice or dispatching an affair; derived from the law of a king of Tenedos, mentioned by Aristotle as quoted by Stephanus, which permitted a person who caught others in adultery to kill both parties with an axe. (See the passages quoted by Eckhel, and Cic. *Ad. Quintum Fr.*, ii. 11.) The head of Apollo also occurs on coins. On the worship of this deity here, and its transmission to Tenea near Corinth, see Müller, *Dorians*, i. 247.

According to Strabo (p. 604) there were two harbours at Tenedos. It was used by the emperor Justinian as a depôt for corn going from Egypt to Constantinople when detained by contrary winds. According to Nymphodorus (Athenæus, xiii. 609) the women of the island were of surpassing beauty.

Tenedos was visited by Chandler, who 'found there but few remains of antiquity worthy of notice. In the streets, the walls, and burying-grounds were pieces of marble and fragments of pillars, with a few inscriptions.' (*Travels in Asia Minor*, p. 20; *Inscriptiones Antiq.*, pp. 3, 4.) The greatest length of the island is from east to west; the town with its harbour is situated in a low and sheltered spot at the north-east corner. In the market-place is the Soros of Atticus, father of Herodes Atticus. (Clarke's *Travels*, ii. 178; who refers to an accurate plan and account of the island in Tournefort, *Voyage du Levant*, i., Paris, 1717.) It contains two hundred Turkish and three hundred Greek houses. To the north of the harbour is a good fortress with forty-two pieces of cannon, but commanded from the heights in the rear. (Frankland's *Constantinople*, i. 232.) The aspect of Tenedos from the sea is barren, but it is cultivated in the interior, and produces wheat and very fine red wine.

TENEMENT is a word employed in descriptions of real property. Though in its usual and popular acceptation it is applied only to houses and other buildings, yet in its original proper and legal meaning it includes everything of a permanent nature that may be holden, whether corporeal or incorporeal. It is sometimes used in a more confined sense, in which it is appropriated to subjects of feudal tenure; but in general it includes not only land, but every modification of right concerning it. Thus the word 'Liberum tenementum,' frank-tenement, or freehold, is applicable not only to lands and other solid objects, but also to offices, rents, commons, and the like. (Harg.; Co. Litt., 154, a. n. 7.)

TENERIFFE, or more properly TENERIFE, called Chinerfe by the original inhabitants, the Guanches, is the largest and most important of the Canary Islands. The most southern cape, Punta Roxa, is in 28° N. lat.; and the most northern, Punta del Hidalgo, in 28° 36′ N. lat. The most eastern part, Punta de Anaga, is in 16° 5′ W. long.; and the most western, Punta de Tena, in 17° 55′ W. long. Its length from south-west to north-east is about 60 miles. Towards the south-eastern extremity it is nearly 30 miles across, but it grows gradually narrower towards the north-east, being near that extremity hardly more than five miles wide. In Humboldt's Travels, the area of the island is stated to be 73 maritime square leagues, or 897 English square miles; but according to a more recent estimate, the area is 83·805 Spanish square leagues, or 1012 English square miles, which is nearly equal to the area of Cheshire.

About one-seventh of the area (comprehending 100,000 acres, or 156·25 square miles) is available for agricultural purposes. The remainder is covered with lava and other volcanic productions, and a great part is destitute of vegetation; a small portion only is covered with trees. The highest ground of the island is the Peak of Teneriffe, called by the inhabitants Peak of Teyde, which name is derived from Echeyde, by which term the Guanches meant Hell. This mountain is situated towards the north-western part of the island, and is a volcano with two summits, of which the south-eastern and more elevated, called Piton, is 11,946 feet above the sea-level, and the north-western, Mount Chahorra, is 9888 feet. Their bases are united by a short ridge, which is somewhat lower than the summit of Mount Chahorra. Both summits are extinct volcanoes. The crater of the Piton, called Caldera, is of oblong shape, and only 300 feet long from south-east to north-west, and 200 feet in the opposite direction. It is distinguished by a

high circular wall which surrounds it, and which would prevent access to the crater, if it were not broken down on its western side. The depression of the crater does not exceed 160 feet. The crater of Mount Chahorra is very large, as it takes more than an hour to go round it: it is about 140 feet deep. It is not on record that volcanic matter has issued from either of them: they are at present only solfataras, from the crevices of which sulphuric vapours are continually arising. But to the west of Mount Chahorra are four volcanic cones, from which in 1798 great quantities of lava flowed and covered the adjacent tracts. In 1706 a great quantity of lava issued from the north-eastern side of the ridge which unites the Piton to Mount Chahorra. These lavas reached the sea and almost filled the harbour of Garachico, which up to that time was the best, or, more properly speaking, the only harbour in the island. Very elevated volcanic masses extend from Mount Chahorra in a north-west direction to the Punta de Tena, which is the most elevated cape of the island. These masses rise to 7000 feet above the sea-level.

The Peak of Teyde is surrounded on the south-west, south, and south-east by an uninterrupted ridge of mountain masses, which form a semicircle, and are about three miles from its base. These mountains are very steep towards the volcano. On the other sides only single mountains occur. The tract which lies between the base of the volcano and the semicircle is called Los Llanos de las Retamas, from a plant called retama, nearly the only plant which vegetates on this tract, which is covered with pumice-stones. Its surface is uneven, but has a regular slope from the base of the volcano towards the masses forming the semicircle. Near the base of the volcano it is about 8000 feet, and near the semicircle about 6000 feet above the sea. The mountains forming the semicircle rise from 1000 to 1800 feet above their base. It is supposed that the Peak de Teyde and the mountains that belong to it cover an area of 120 square miles.

From the outer edges of the semicircle the country descends in rapid and broken slopes towards the sea on the west and on the north, but on the south and east the semicircle is surrounded by table-lands, whose surface is likewise much broken, but which at the distance of several miles preserve an elevation of between 4000 and 6000 feet above the sea. These table-lands are most extensive to the east, where they terminate, about 20 miles from the semicircle, on the Plain of Laguna. These table-lands and the volcano taken together probably cover nearly half the island. In many places the table-lands and the slopes of the hills which cover it are overgrown with pines, but the greater part consists of bare volcanic rocks or lava. No part of them is cultivated, with the exception of a small portion in the vicinity of Chasna, south of the semicircle, where corn is grown, and where there are extensive plantations of fruit-trees. On the edge of the table-land, west of Guimar, is a small volcano, which made an eruption in 1705.

The Plain of Laguna is traversed by 16° 20′ W. long. West of that plain the cultivable country is found only near the sea, and from three to four miles from it, with the exception of the table-land of Chasna, which is more than eight miles distant. The cultivable tract along the sea is so uneven that it is almost impossible to find a square mile which can be called level. A portion of it rising in steep and sharp ridges cannot be cultivated, but where the declivities are moderate the soil generally repays the labour bestowed on it. The most fertile tract is on the north side of the island, between Tegina and San Juan de la Rambla, especially west of Santa Ursula, which portion is called the Valley of Taoro. The soil consists of a mixture of sand, volcanic matter, and some clay, and produces rich crops of wheat and all kinds of fruit, especially grapes. West of San Juan de la Rambla are a few fertile valleys, but a great part of the country is covered with recent lava. The most sterile part lies along the west coast, between Punta de Tena and Punta Roxa, where there are only a few narrow valleys, and where a tract several miles in length on both sides of Puerto de los Christianos is quite barren. Between Punta Roxa and Santa Cruz there are several fine valleys, which have a fertile soil composed of decomposed pumice-stone and tufa intermixed with gravel; but their fertility cannot be compared with that of the valley of Taoro, which is mainly to be ascribed to the smaller quantity of rain which falls on the southern shores.

The plain of Laguna occupies the middle of the island, near 16° 20′ W. long.: it is about 1700 feet above the sea, and enclosed by hills; the surface is nearly a dead level, occupying a space of about 12 square miles. After the rains it is partly covered with water, and hence is derived its name. The soil consists of a reddish clay, and produces abundant crops of grain, but no part of it is covered with trees.

The eastern portion of the island, or the peninsula which extends east of the plain of Laguna, is only hilly in comparison with the western portion, as the highest summit, the Bufadero, rises only to 3069 feet above the sea-level. In this part no traces of lava and no volcanic cones occur: the hills consist mostly of black basalt: the valleys are numerous, but narrow. These valleys and the adjacent hills are cultivated and planted with trees where the surface is not too steep: they produce the finest fruits in the island. The country descends gradually towards the east, and Punta de Anaga is only elevated a little above the sea-level.

Climate.—Teneriffe, being situated near the tropic, partakes of the climate both of the countries within and without the tropic: it has only two seasons, a rainy and a dry season, but the rainy season does not occur when the sun is nearest, as in the tropical countries, but when it is near its greatest southern declination. It occurs in the same period of the year as in southern Europe. The dry season is produced by the trade-winds, which, when the sun approaches the northern tropic, proceed farther north, and are met with at 30° and even 33° N. lat. These winds blow on Teneriffe without interruption from April to October, and always from the east-north-east: they are strongest from the middle of May to the middle of August. The wind begins in the morning between ten and eleven o'clock, and continues to five or six in the afternoon, when it is followed by a calm, which lasts till midnight. From midnight to seven or eight o'clock the land-breezes blow, and they are again followed by a calm, which lasts till the trade-wind sets in. Along the western shores of the island these winds are not felt, but there is a continual calm, which extends about 15 miles into the sea. The trade-wind renders the communication between the islands tedious and difficult. From Teneriffe a vessel can run to Hierro in less than one day, but to return from Hierro to Teneriffe it generally takes ten or twelve days, and sometimes even three or four weeks. A voyage from Madeira to Teneriffe is made in two days, but it takes more than a month to sail from Teneriffe to Madeira. During the prevalence of the trade-winds the weather is constantly fine, and not a drop of rain falls.

In the rainy season, from October to April, south-west winds prevail: in October the winds turn to the east and south-east, and then the summit of the Peak of Teyde begins to be covered with clouds which proceed from the south. These clouds accumulate on the Peak, and gradually descend lower. When they have sunk to about 6000 feet above the sea-level, and cover the most elevated part of the island, they produce terrible thunder-storms. The rain begins to descend in torrents on the sides of the mountains, and the summit of the peak is covered with snow. In summer the mountain is quite free from snow, which is only found in a deep depression on the northern slope. This depression is called Cueva del Yelo. The snow rests on the mountain about four months. At the beginning of November the wind is settled in the south-west, and whilst it blows the rains sometimes last for three days. In February, March, and April the wind turns to the west-north-west, north-west, and north-north-west, and the rains decrease gradually. They cease at the end of March.

The climate of Teneriffe and of the Canary Islands in general is disagreeably affected by the wind called El Levante, which comes from the south-east, and generally blows before or after the beginning of the rainy season. Its effect on all organic bodies is very great, and the heat which it brings from the Sahara is felt much more in elevated places than near the sea-shore, the more so as water is very scarce in those parts, and the thirst which the wind produces is intolerable. In those higher places it blows with such force that it frequently throws down men and horses. The air is misty, and it is not possible to distinguish objects even at a moderate distance; but there are no clouds in the sky. Sometimes this wind brings locusts in large numbers to the island. It was

formerly thought that these insects reached the island by flying, but MacGregor states that such immense numbers of them are carried from the Sahara into the sea as to form a thick layer; and that in this way they are carried to the Canary Islands, and that most of them are dead when they arrive there, but those which cover the upper surface are alive, and spread their devastation over the corn-fields and plantations.

We subjoin the meteorological observations made at Santa Cruz and at Laguna: the last-mentioned place is about 1700 feet above the sea.

	Jan.	Feb.	Mar.	April	May.	June.	July.	Aug.	Sept.
Santa Cruz	63·83°	64·34°	67·16°	67·32°	72·12°	73·89°	77·27°	78·89°	77·42°
Laguna .	55°	55°	58°	59°	62°	65°	69°	71°	70°

	Oct.	Nov.	Dec.	Winter	Spring	Sum.	Autm.	Ann. mean.
Santa Cruz	74·66°	70·43°	65·81°	65·11°	71·11°	77·86°	70·11°	71·04°
Laguna .	66°	62°	53°	56·33°	62·00°	70·00°	62·00°	62·83°

This table shows that the climate of Teneriffe is distinguished by its moderate temperature, and that the heat of the summer is prolonged to the month of November, October being considerably warmer than May, and November than April.

Productions.—All European domestic animals are reared, and also white camels, which are used as beasts of burden, and reared on the west coast of the island, but not in large numbers. Cattle are rather scarce, on account of the want of pasture-ground. They are only kept for slaughter and for the plough: the cows are never milked. Horses are still less numerous. They are of good breed, of a middling size, and very hardy. Goats are very numerous, and their milk is exclusively used, and butter of a white colour, called 'mantequilla,' and a large quantity of cheese, are made of it. These goats are of a peculiar breed, which existed on the island before the arrival of the Europeans. They constituted the principal riches of the Guanches. Sheep are also numerous. The breed is small, and the wool is coarse, but abundant: it is consumed in the island. Asses are rather numerous, but small: mules are much used as beasts of burden. According to MacGregor, the number of cattle is about 4900, of horses 1000, of camels 60, of mules 1400, of asses 2200, of goats 30,000, of sheep 18,000, and of hogs 3000. The silk-worm is extensively reared, and the annual produce of silk may amount to 8000 lbs., but it fetches a less price than the Italian silk, not being so well prepared. In 1828 the cochineal insect was introduced, and the first trials at rearing it succeeded very well. We are not acquainted with the result of this attempt. Bees are abundant, domestic as well as wild. The honey is of the best quality, especially that which is collected in the neighbourhood of the Peak of Teyde, which is extracted by the bees from the blossoms of the retama plant. Between 7000 and 8000 lbs. of wax are annually collected. Rabbits are very numerous.

The domestic birds are fowls, ducks, geese, and pigeons. A great number of turkeys are reared. The number of wild birds is very great. Some of them are always found on the island, and others arrive only at certain seasons, in their migration from north to south, and *vice versâ*. The most remarkable belonging to the first class are the wild pigeon, various species of Tetraonidæ, quails, and larks. The canary-bird is common. Fish is far from being abundant. The inhabitants live mostly on potatoes and salt fish, which is obtained from the fishery on the coasts of Africa [SAHARA, vol. xx., p. 317]; but of late the inhabitants of Teneriffe have abandoned this branch of industry, and buy the fish from the fishermen of the other islands. Whales are sometimes met with among the Canary Islands, and still more frequently dolphins. Seals rarely visit the coast.

The principal objects of agriculture are potatoes, wheat, maize, barley, and rye. Where the soil is good, and means of irrigation are at hand, two crops of maize, and one of potatoes, or two of potatoes and one of maize, may be raised in twelve months. According to an average of five years (1800-1804), the annual produce was about 70,000 quarters of potatoes, 21,700 quarters of wheat, 6511 quarters of maize, 5533 quarters of barley, 2200 quarters of rye, and only 40 quarters of oats. It is however stated that since that time the cultivation of grain, and especially that of potatoes, has considerably increased. Other objects of cultivation are flax, canary-seed, sumach for the tanneries, pumpkins, cucumbers, yams, cabbage, peas, Turkish beans, garbanzos, lentils, lettuce, capsicum, onions, and garlic. The orchards produce apples, pears, cherries, plums, apricots, peaches, mulberries, almonds, chesnuts walnuts, figs, Indian figs, oranges, and lemons, and also plantains, pine-apples, dates, pomegranates, papayas, guavas, anonas, and a few other fruits derived from the West Indies. The most important object of cultivation is the vine, which yields the largest article of export. According to an average of five years (1800-1804) the annual produce amounted to 24,846 pipes, each containing 100 gallons, but it is stated that to this quantity from 5000 to 8000 pipes must be added, which during the vintage were converted into brandy. Thus the annual produce amounted to about 30,000 pipes. But the war between Spain and its American colonies, to which a large quantity of wine and brandy was exported, has considerably diminished this branch of industry, and at present the annual produce hardly exceeds 20,000 pipes. The best sort, known by the name of Vidonia, resembles Madeira, and is sent to England. The Malvasia wine was formerly in great request, but the demand for it has diminished. The difficulty of obtaining a remunerating price for their wines and brandies has of late induced the inhabitants to introduce some other objects of cultivation. Cotton has begun to be cultivated; the produce resembles that of Pernambuco. They have also made some successful trials with coffee. Two centuries ago the sugar-cane was the most important branch of cultivation, but at present there is only one sugar-mill on the island.

Large forests still cover some of the higher parts of the island, though they have been greatly reduced. Among the trees there are numerous kinds of Laurus, as L. Indica, L. barbussana, L. nobilis, &c. Two or three wild-growing plants are used for making barilla, and the Mesembryanthemum crystallinum is cultivated for that purpose on a small scale. Two kinds of lichens which grow on the rocks are collected for their dyeing qualities: the roccella tinctoria, which yields the archil, and the parella: they are mostly sent to England.

Teneriffe has no metals, except some iron-ore, of which no use is made. Sulphur occurs in large quantities on the Peak of Teyde.

Population and Inhabitants.—According to an estimate of MacGregor, founded on the old census of 1802 and other data, the population of Teneriffe amounted, in 1829, to 85,000 individuals; so that on the average there were 84 persons to each square mile. The greater part of the tribe of Guanches, who inhabited the island at the arrival of the Spaniards, perished in the war by which the Spaniards got possession of it, and the remainder intermarried with the Spaniards. The present inhabitants must therefore be considered as Spaniards, whom they also resemble in person and character. The Spanish language alone is spoken, intermixed in the parts remote from the towns with a few other words.

Political Divisions and Towns.—For the administration of justice the island is divided into three jurisdictions, the courts for which are at Santa Cruz, Laguna, and Orotava. Santa Cruz de Santiago, the seat of the governor-general of the Canary Islands, is built on the south coast of the island, not far from its eastern extremity. The harbour is not large, and is well protected against the winds, except those that blow from the south. At the distance of from 75 to 100 fathoms from the land there is good anchorage in 6 to 12 fathoms, and half a mile off in 25 to 30 fathoms. The lowest part of the town is more than 20 feet above the sea-level, and the ground rises gently. The houses are built in the Spanish Moorish fashion, with a court-yard (patio) in the middle, and have only one floor. The streets are straight, but narrow, and have foot-pavements. The population amounted, in 1829, to 8620 individuals. The place carries on a considerable commerce, and the harbour is annually visited by 80 to 100 vessels.

San Christoval de la Laguna is considered the capital of the island, being the seat of administration. It is built in the middle of the plain of Laguna, and is a pleasant place. The streets are straight and wide, well paved, and have foot-pavements. Most of the houses have only one floor. The population amounts to more than 10,000. The rich inhabitants of Santa Cruz pass the summer months here, as the climate of Laguna is much cooler.

Taeoronte, not far from the northern coast, in a fine valley, has 4600 inhabitants.

Orotava is on the declivity of a steep hill, nearly 1200 feet above the sea-level: it is a well-built and thriving place, with nearly 8000 inhabitants. It carries on a considerable commerce by means of its harbour, called Puerto de la Orotava, which is about 2 miles distant, and contains a population of 4600.

Guimar, on the southern coast, is in a very fertile valley, which produces much wine and wheat: it is rather well built, and contains 3500 inhabitants. In the vicinity are the tombs of the antient inhabitants, the Guanches, which contain mummies.

Manufactures and Commerce.—There are a few manufactures of silk stuffs at Icod de los Vinos, a town on the north coast, with 4000 inhabitants. These manufactures were formerly very active, and their produce went to America; but they are now in a declining state, especially since the population of Teneriffe have begun to wear cotton instead of silk. Linen and woollen stuffs are made by the families for their own consumption. Woollen stockings were formerly made for the American market, but this branch of industry has entirely ceased. Earthenware, especially large water-filters, is still sent to Cuba and Puerto Rico. There are manufactures of soap and vermicelli at Santa Cruz. The tanneries produce a very indifferent leather, which is not exported. The number of distilleries is large, and the brandy is hardly inferior to Cognac. Ropes are made from the agave; and hats, baskets, and mats from the leaves of the date-palms. Good cabinet-work has lately begun to be made for the South American market.

The maritime commerce is concentrated in the port of Santa Cruz and Port Orotava, which are annually visited by about 120 vessels, mostly English. The inhabitants have a few vessels, with which they visit the American harbours. The most active commerce is that with England, in which about 80 vessels are constantly employed. The imports consist of iron utensils, hardware, iron in bars, flax, glass-ware, crockery, leather, candles, soap, large quantities of cotton goods, provisions, cod, and some minor articles. The most important exports are wine, brandy, and barilla: there are also exported almonds, dry fruits, raw silk, and archil. The commerce with the United States of America and with Hamburg is also considerable.

History.—The Canaries were known to the antients, who called them the Fortunate Islands. [CANARIES, vol. vi., 226.] Teneriffe was occupied by the Spaniards in 1496, and has always remained in their possession.

(Glas, *History and Conquest of the Canary Islands;* Humboldt, *Voyage aux Régions Equinoxiales du Nouveau Continent*, vol. i.; Von Buch, *Physikalische Beschreibung der Canarischen Inseln;* and *Die Canarischen Inseln nach ihrem gegenwärtigen Zustande*, von Mac Gregor, Hannover, 1831.)

TENIERS, DAVID (the Elder), was born at Antwerp in 1582. He had the good fortune to study painting under Rubens, who highly esteemed him for his promising genius. Besides the benefit of the instruction of that great master, he had the advantage of learning his manner of preparing his grounds and managing his materials. It is said that he began by painting pictures on a large scale; but having gone to Rome with the intention of improving himself in the higher branches of the art, he there contracted an intimate friendship with his countryman Adam Elsheimer, whose exquisitely-finished cabinet pictures were greatly esteemed, and he studied with him several years, painting only small pictures. It was here that he acquired the neatness of pencilling for which his works are esteemed, and which, with the knowledge of colours acquired under Rubens, gives to his works so great a charm.

Returning to his native country after ten years' absence, he devoted himself with the greatest ardour to the practice of his art, and chose the familiar scenes of ordinary Flemish life, such as merry-makings, weddings, the interior and exterior of public-houses, rural games, chemists' laboratories, and grotesque subjects, such as the Temptation of St. Anthony and the like. These subjects he treated with the utmost truth and fidelity to nature. His colouring, his touch, his design, the pleasing distribution of light and shade, the skilful composition of his groups, procured him great reputation and constant employment: every lover of the art was eager to possess some of his works. He may in fact be considered as the inventor of a new manner, which was followed and carried to a still higher degree of perfection by his son. He died at Antwerp in the year 1649, at the age of sixty-seven.

TENIERS, DAVID (the Younger), was born at Antwerp in 1610, and received his first and principal instruction from his father. Some authors have affirmed that he left his father to become a disciple of Adrian Brouwer, who however was only two years older than himself, and that he had the advantage of the precepts of Rubens. Others have pretended that he was likewise a pupil of Elsheimer, who died when Teniers was only ten years old. He adopted, as we have observed, the subjects and style of his father; but, with a more fertile imagination, he produced compositions much more varied and ingenious; his colouring is more vivid, rich, and transparent, and the facility of his execution is enchanting. He studied nature in all her varied forms with the most critical attention. He possessed, in perfection, what we have heard one of the brightest living ornaments of the British school call 'the art, or rather the gift, of seeing.' Hence the truth and nature of his pictures, which look almost like reflections in a convex mirror. His pencil is free and delicate; the touching of his trees light and firm; his skies are admirably clear and brilliant, though not much varied. The expression of his figures, in every varying mood, of mirth or gravity, good or ill humour, is strongly marked, striking, and natural; he represented them however precisely as he saw them before him, but was perhaps inferior in delineation of character to Jan Steen or Wilkie.

It is remarkable that at the commencement of his career very little regard was shown to his merit, so that he was often obliged to go in person to Brussels to dispose of his pictures. But he was not long neglected. The archduke Leopold having seen some of his pictures, immediately distinguished him by his patronage, appointed him his principal painter and gentleman of his bedchamber, presented him with a chain of gold to which his portrait was affixed, and gave him the direction of his gallery of paintings, which contained works of the most eminent masters of the Italian and Flemish schools. Teniers, who possessed an extraordinary talent in imitating the works of other artists, made copies of this gallery, in which the touch, the colouring, and the manner of the several painters, however different from each other, were reproduced with such a deceptive fidelity, that he acquired the name of the Proteus of painting. Some writers have objected that his figures are too short and clumsy, and that there is too much sameness in their countenances and habits: but it must be remembered that he designed every object as he saw it; and the charm which his art has thrown on scenes flat and insipid in their forms, even subjects low, barren, and commonplace, justly excites the admiration of all lovers of the art, and the extraordinary prices which are given for his works in every part of Europe are an incontestible proof of the universal admiration and esteem in which they are held. This circumstance is the more deserving of attention, as his works, far from being scarce, are extremely numerous: his extraordinary facility of execution and the great age to which he attained enabled him to produce such a number of pictures, that he was used to say in joke that to hold all his paintings (though they were of such small dimensions) it would be necessary to build a gallery two leagues in length. It is worthy of remark that while of all the Flemish painters his works are the most popular, he was habitually conversant with the higher classes of society. The suavity of his manners and his irreproachable conduct secured him the esteem of all his countrymen. Besides the archduke Leopold, he was honoured with the favour and protection of Christina, queen of Sweden, the king of Spain, Don John of Austria, who became his pupil, the Prince of Orange, the bishop of Ghent, and other eminent personages. He often assisted the landscape-painters of his time by inserting figures into their pictures, and many works of Artois, Van Uden, Breughel, and others derive additional value from this circumstance. The galleries and collections in England contain a great number of his finest works. He died at Brussels, in the year 1694, at the advanced age of eighty-four years.

TENIMBAR ISLANDS. [SUNDA ISLANDS, LESSER.]

TENISON, THOMAS (born 1636, died 1715), an Eng-

lish divine, son of a clergyman in the diocese of Ely, who was advanced by his own deserved reputation for piety, charity, learning, and liberality, to the highest station in the English church. He was born at Cottenham in Cambridgeshire, educated in the grammar-school at Norwich, from whence he passed to Corpus Christi College, Cambridge, where he was admitted in 1653, and took his bachelor's degree in 1657. The university was then in the state to which it had been brought by the parliamentary commissioners, and the turn of mind of Tenison not according with what at that time was expected from persons undertaking the ministry, he for a time turned to the study of medicine; but about 1659 he was privately ordained in the episcopal method then proscribed by the government of the time. The ordination was performed at Richmond in Surrey by Dr. Duppa, the expelled bishop of Salisbury. The restoration of the king, and with it of the episcopal church, soon following, he was made minister of St. Andrew's Church in Cambridge, in which situation he gained much credit by his attention to his parishioners during the time of the plague, in 1665. He had other preferment in the country, as the church of St. Peter Mancroft in Norwich, and the rectory of Holywell in Huntingdonshire. This brings down his history to the year 1680, when, being then doctor in divinity, he was placed on a more conspicuous stage, being presented by King Charles II. to the living of St. Martin's in the Fields.

In this public situation he acted with great prudence, and with a liberality which emulated the munificence of the clergy of earlier times, giving more than 300*l.* to the poor of his parish in the time of the distress occasioned by the hard frost of 1683, and endowing a free-school, and building and furnishing a library. In 1685 he discharged the difficult duty of attending the duke of Monmouth previous to his execution with singular discretion. In his politics he was a Whig, and favourer of the Revolution, and was accordingly early marked out by King William for advancement in the church. In 1689 he was made archdeacon of London, and in 1691 bishop of Lincoln. This large diocese, which had been too much neglected, he brought into order. In 1694, on the death of Dr. Tillotson, he was made archbishop of Canterbury, in which high dignity he remained for twenty years. He died on the 14th of December, 1715, and was interred in the parish church of Lambeth.

A large account of his life was published soon after his death, without the name of any author in the title-page, but evidently written by a person possessed of good information, and who was fully sensible to his merits. He speaks of him thus:—'And as he was an exact pattern of that exemplary piety, charity, stedfastness, and good conduct requisite in a governor of the church, so perhaps since the primitive age of Christianity and the time of the Apostles there has been no man whose learning and abilities have better qualified him to discharge and defend a trust of that high importance.'

The library which he founded in the parish of St. Martin's still exists; and he may be regarded as the founder of the library in the cathedral church of St. Paul, having presented two hundred and fifty pounds to make up four hundred and fifty, which the dean and residentiaries gave for the libraries of two clergymen bought by them in 1707. His will contains many munificent bequests for charitable and religious objects.

Archbishop Tenison has left no writings behind him which can be said to make part of the general literature of the country, or to establish for him a literary reputation. Yet he published several treatises, mostly connected with the religious and political controversies of his age.

TENNANT, SMITHSON, a distinguished chemist, was born at Selby, in Yorkshire, November 30, 1761, and died February 22, 1815. He was the only child of the Rev. Calvert Tennant, of whom little is known except that he had been a Fellow of St. John's College, Cambridge, and was a friend of Dr. Rutherford, Regius Professor of Divinity in that University.

While very young he gave many proofs of a particular turn for chemistry and natural philosophy, and after quitting school he was very desirous of completing his chemical studies under the immediate instruction of Dr. Priestley, who was then enjoying high and deserved reputation for the extent and variety of his discoveries in pneumatic chemistry; but this was found impracticable in consequence of the previous engagements of Dr. Priestley.

In the year 1781 he went to Edinburgh with the intention of studying medicine. Of his companions, occupations, or studies while in Scotland, little is known, except that he received instruction from Dr. Black; he did not however continue long in that University, for in October, 1782, he was admitted a member of Christ's College, Cambridge, where he then began to reside.

In the summer of 1784 he travelled into Denmark and Sweden, with the intention, partly of examining the mines of the latter country, but chiefly with the view of becoming personally acquainted with Scheele, for whom he had conceived a high degree of admiration, especially on account of the simplicity of the apparatus which he employed in his chemical researches. In a year or two afterwards he went to Paris, where he became acquainted with some of the eminent chemists; thence he went to Holland and the Netherlands, after having recovered from a serious illness with which he was seized during his residence in the French capital.

In January, 1785, he was elected a Fellow of the Royal Society, and in 1786 he left Christ's College and removed to Emmanuel College; in 1788 he took his degree as bachelor of physic, and soon after quitted Cambridge and came to reside in London. In 1796 he took a doctor's degree at Cambridge, but as his fortune was independent, he relinquished all idea of practice as a physician. In 1813 he was elected Professor of Chemistry at Cambridge, having in the previous year delivered, with great success, a few lectures on the principles of mineralogy to some of his friends.

In the month of September, 1814, Mr. Tennant went for the last time to France, and on his return home on the 20th of February, 1815, he arrived at Boulogne with Baron Bulow, in order to embark there. They embarked on the 22nd, but were forced back by the wind, and meant to embark again in the evening: in the meantime they took horses and went to see Bonaparte's pillar, about a league off, and going off the road on their return to look at a small fort, of which the drawbridge wanted a bolt, they were both thrown, with their horses, into the ditch. Baron Bulow was merely stunned, but Mr. Tennant's skull was so severely fractured, that he died within an hour after.

The following character of Mr. Tennant is chiefly copied, with some variations, from the 'Annals of Philosophy,' vol. vi., and the writer of this brief notice, having well known the subject of it, is able to testify to the accuracy of the statements in all the more important particulars.

Mr. Tennant was tall and slender in his person, with a thin face and light complexion. His appearance, notwithstanding some singularity of manners, and great negligence of dress, was on the whole striking and agreeable. His countenance in early life had been singularly engaging; and at favourable times, when he was in good health, was still very pleasing. The general cast of his features was expressive, and bore strong marks of intelligence; and several persons have been struck with a general resemblance in his countenance to the well-known portraits of Locke.

Of his intellectual character, the distinguishing and fundamental principle was good sense; a prompt and intuitive perception of truth, both upon those questions in which certainty is attainable and those which must be determined by the nicer results of moral evidence. In quick penetration, united with soundness and accuracy of judgment, he was perhaps without an equal. He saw immediately and with great distinctness where the strength of an argument lay, and upon what points the decision was ultimately to depend; and he was remarkable for the faculty of stating the merits of an obscure and complicated question very shortly, and with great simplicity and precision. The calmness and temper, as well as the singular perspicuity, which he displayed on such occasions, were alike admirable; and seldom failed to convince the unprejudiced, and to disconcert or silence his opponents. He had a peculiar cast of humour, which was heightened by a perfect gravity of countenance, a quiet familiar manner, and a characteristic simplicity of language. In consequence, principally, of the declining state of his health, his talent for conversation was perhaps less uniformly conspicuous during his latter years, but his mind had lost none of its vigour, and he never failed, when he exerted himself, to display his peculiar powers.

The 'Philosophical Transactions' contain eight papers by Mr. Tennant:—1, 'On the Decomposition of Fixed Air,'

1791; 2, 'On the Nature of the Diamond,' 1797; 3, On the Action of Nitre upon Gold and Platina;' 4, 'On the Different Sorts of Lime used in Agriculture,' 1799; 5, 'On the Composition of Emery,' 1802; 6, 'On two Metals found in the Black Powder of the solution of Platina,' 1804; 7, 'On an easier Mode of procuring Potassium than that which is now adopted;' 8, 'On the Mode of producing a Double Distillation by the same Heat.'

In the first volume of the 'Transactions' of the Geological Society, 1811, he published the analysis of 'A Volcanic Substance containing the Boracic Acid.'

In his experiments on the diamond, he proved it to be pure carbon, by heating it in a gold tube with nitre; the diamond was converted into carbonic acid by combining with the oxygen of the decomposed nitric acid, and this united with the potash of the nitre; by the evolution of the carbonic acid, the quantity of carbon, in a given weight of diamond, was estimated. In his paper on 'Limestones,' he showed that the presence of carbonate of magnesia in them rendered them prejudicial when calcined and applied as a manure.

In the paper on 'Emery,' he proved that this substance is merely a variety of corundum, or sapphire. The two metals which he found in native platina were osmium and iridium.

With respect to these memoirs it may be observed that they all bear the impress of originality, and that the operations which they include and describe are of the greatest possible simplicity, and stated in the plainest language.

TENNANTITE, a variety of grey copper-ore, so named in honour of Smithson Tennant, a distinguished chemist. It occurs in attached crystals, which are usually small. Primary form a cube. Cleavage parallel to the planes of the regular octohedron. Fracture uneven and imperfectly lamellar. Hardness: scratches carbonate of lime, but is scratched by the phosphate. It is brittle. Colour varying from tin-white to blackish iron-grey, frequently tarnished on the surface. Streak reddish-grey. Lustre metallic, sometimes splendent. Specific gravity 4·375.

When heated by the blowpipe, it decrepitates, and burns with a blue flame, emitting arsenical vapours, and then fuses into a black scoria, which is attracted by the magnet.

It occurs only in Cornwall, and has there been found in several copper-mines.

TENNESSEE is one of the inland states of the North American Union, and lies between 35° and 36° 40′ N. lat. and between 81° 30′ and 90° W. long. The southern boundary, which runs along 35° N. lat., is contiguous to the northern limits of the states of Georgia, Alabama, and Mississippi, and is 356 miles long, of which the boundary with Georgia amounts to 100, that with Alabama 140, and that with Mississippi 116 miles. On the west of it are Arkansas and Missouri, from which it is separated by the Mississippi, whose course along this border amounts to about 150 miles, measured along the numerous bends. North of Tennessee are Kentucky and Virginia. The boundary-line towards Kentucky between the rivers Mississippi and Tennessee runs along 36° 30′ N. lat. for about 64 miles, but east of the last-mentioned river it follows its course for about 12 miles until it reaches 36° 40′ N. lat. and 36° 33′ W. long., and then extends a little south of east until it meets the south-western angle of Virginia near 83° 30′ W. long. The distance between the Tennessee river and the last-mentioned point is about 250 miles. The line which divides Tennessee from Kentucky is continued eastward between Tenessee and Virginia for 105 miles, when it arrives at the most eastern point of the state. East of Tennessee is North Carolina; the boundary-line between them, which is 150 miles long, is formed by one of the ranges of the Appalachian Mountains, called the Iron Mountains. The length of Tennessee from east to west is about 445 miles, and its breadth from north to south 104 miles. The area is about 40,200 square miles, or 26,728,000 acres. It is about 10,000 square miles less in extent than England without Wales.

Surface and Soil.—This state is naturally divided into three regions, which may be called the Eastern or Mountain region, the Middle or Hilly region, and the Western or Level region; and this division coincides tolerably well with that made for the administration of justice, according to which the country is divided into the Eastern, the Middle, and the Western District. The first and the last are nearly equal in extent, each comprehending about 10,000 square miles, but the Middle District is about double that size.

The *Eastern* or *Mountain Region* lies within the ranges of the Appalachian Mountains. This extensive mountain-system may be said to commence along and near the southern boundary-line of Tennessee. Near 35° N. lat. and 82° W. long., on the boundary-line between South and North Carolina, the country forms a ridge of hills, a continuous high ground which extends westward to 85° W. long., a distance of more than 160 miles. In the Carolinas it is known by the name of the Blue Ridge. It does not terminate at 85° W. long., but west of that meridian it forms a kind of mountain-knot, consisting of several ridges, which extend south-west and north-east, in the direction of the whole mountain-system. These ridges lie between 34° and 35° 20′ N. lat., and the Tennessee river traverses this tract in a south-west direction. The highest of these ridges is on the east of the river valley, and is called the Look-out Mountains. The elevated ground just mentioned constitutes the southern extremity of the Appalachian Mountains; for from its eastern extremity, west of 82° W. long., a ridge runs in a general north-east direction, which is also called the Blue Ridge, being considered as the continuation of the before-mentioned ridge so called, and from its western termination (near 86° W. long.) there runs another ridge under the name of the Cumberland Mountains, first north-north-east, and afterwards east-north-east and north-east. The space included between these two ranges extends from east to west about 200 miles. It is traversed by several minor ridges, among which the most elevated and least interrupted is called the Iron Mountains. It extends south-west and north-east, is much nearer the eastern Blue Ridge than the Cumberland Mountains, which are west of it, and constitutes the boundary-line on the east between North Carolina and Tennessee.

The mountain-region of Tennessee occupies the tract enclosed by the Iron Mountains and the Cumberland Mountains, whose most elevated parts are about 70 miles distant from one another. The northern half of this tract is traversed by three minor ridges, which in general run parallel to the larger ranges, and thus with the two outer ranges form four valleys, which are traversed by four of the upper branches of the Tennessee River, namely, Powell's, Clinch, Holston, and Frenchbroad River. The valleys are rather wide, but as there is little alluvial land along the watercourses, their surface is uneven and broken, and the soil, which consists mostly of siliceous gravel, is of indifferent quality, except in the valleys of the Holston and Frenchbroad rivers, where it contains a mixture of clay. Only a comparatively small portion of it is strong enough for the growth of wheat; the greater part produces rye and oats; but the mountains afford good pasture-grounds, and large herds of cattle and sheep are kept. The most elevated part of the mountains is overgrown with forests of pitch-pine, which yield timber, and from which tar, pitch, and turpentine are extracted. The minor ridges terminate near 35° 50′ N. lat., where the upper branches of the Tennessee river form their union. The country south of 35° 50′ can only be called mountainous near the southern portion of the Blue Ridge and the Cumberland Mountains, the interior being covered by a succession of hills rising hardly more than 300 feet above their base. The soil of this tract is of indifferent quality, and mostly used as pasture-ground, but the forests contain many large trees, as pitch-pine, red cedar, and black walnut. Along the watercourses there are some tracts of moderate extent fit for the growth of rye and oats.

The *Hilly* or *Middle Region* extends from the Cumberland Mountains westward to the Tennessee River, where it traverses the state by running from south to north. The general level of this region is several hundred feet above the sea-level, and it is covered with numerous hills, which form several continuous ridges, such as that which, under the name of Elk Ridge, runs from east to west near 35° 20′ N. lat. between the Elk River and Duck River. The watercourses are usually much depressed below the general level,

and most of them run in narrow channels. This tract varies greatly in fertility. Near the Cumberland Mountains, and to the distance of 20 miles from them, the soil consists chiefly of gravel mixed with limestone, and is of moderate fertility, but in general it is better than in the mountain-region, and larger tracts are fit for the growth of wheat. The country west of this tract is the most fertile portion of Tennessee: it extends over the whole of the state from north to south, and reaches westwards to 87° W. long. The soil is not inferior to the best part of Kentucky, and consists of a large portion of clay and loam mixed with sand and gravel. A large quantity of wheat is produced, but the staple articles are tobacco and maize. In the better lands, especially along the Cumberland River, the common produce of maize is from 60 to 70 bushels for one, and in other places 40 or 50. The forests, which still cover a great part of the surface, consist chiefly of ash, elm, black and honey locust, mulberry, sugar-maple, and the wild plum; and wild grapes are abundant. The western districts, or those which lie near the Tennessee River, and extend about 30 miles east of it, are less hilly, but they are also less fertile: they produce the same articles, but the crops are less plentiful. In some places cotton is cultivated.

The *Western* or *Level Region* lies between the Tennessee and Mississippi rivers. The surface is traversed by some swells of high ground: the most extensive is that which runs across the state from north to south, about 12 miles from the western bank of the Tennessee River, and is several miles wide. Other swells traverse the southern districts, running from south-east to north-west, and terminating on the banks of the Mississippi with the Chickasaw Bluffs. The north-west districts are nearly a dead level, which descends imperceptibly to the banks of the Mississippi, where it terminates in a large wooded swamp, called the Wood Swamp. This region was very thinly inhabited twenty years ago, but it cannot be of indifferent quality, if we judge by the rapidity with which the population has increased. It appears however that the more elevated portions of the country are much more thickly settled than the level tract, which may be attributed to the circumstance that the last-mentioned tract contains many swampy places, and is less favourable to health. In these regions every kind of grain is grown, and cotton and tobacco are extensively cultivated.

Rivers.—Numerous rivers drain this state, and some of them have a long course. The larger rivers are navigable for keel-boats and for steam-boats, but only during the boating-season, which generally commences on the 20th of February, and terminates early in June. Occasional freshets contribute to render them navigable during a short portion of the other months, but no reliance can be placed on periodical returns of freshets, except those of the spring season.

The Tennessee River rises with numerous branches in the Appalachian Mountains: the most remote of them originate in Virginia near 81° 20′ W. long. and and 37° N. lat., and run south-west. The largest branches are the Clinch and Holston rivers: they unite with other branches, which rise in North Carolina, in the country enclosed by the Blue Ridge and the Iron Mountains, and which break through the last-mentioned chain. The largest of them are the Frenchbroad River, the Tennessee, and the Hiwassee. After these numerous branches have united, the Tennessee traverses the mountain-knot between 34° and 35° 20′ N. lat. It passes through the ridge, which on the south is called Look-out Mountains, and on the north Walden's Range. It rushes through this gap with great impetuosity over a rocky bed: this place is called the Suck: its course within the mountain-tract is very rapid, and it escapes from it by another gap near Fort Deposit, in Alabama. At this place it changes the south-west course into a western course, and after draining Alabama for about 200 miles, it returns to Tennessee. In Alabama the river widens from two to three miles, and in this part there are extensive rocky shoals, which are known under the name of the Mussel Shoals, and occupy for seven or eight miles the whole of the bed. In low-water these rocks entirely obstruct the navigation, but in the time of the freshets boats of moderate size may ascend and descend without danger. The lower course of the Tennessee River, as far as it lies within Tennessee, is from south to north. After having entered Kentucky it gradually declines to the west, and falls into the Ohio. The whole course of the Tennessee probably does not exceed 800 miles, reckoned from the source of the Holston or Clinch. In the boating season it may be ascended by large river-boats to the Mussel Shoals, and even to the gap by which it escapes from the mountains by small boats. Some of its upper branches are navigable for small boats above the Suck. It appears that within the Appalachian Mountains it may be descended by boats, but the ascent is very laborious and even dangerous.

The Cumberland River rises in Kentucky, in the valley formed by the Cumberland Mountains and the Laurel Mountains, and traverses the south-eastern district of that state by a general western course: after a run of about 150 miles it turns to the south-west and enters Tennessee, where it soon resumes its western course. It drains the northern districts of Tennessee by a course of about 200 miles; and turning gradually more to the north, re-enters Kentucky, where its general course is to the north. It falls into the Ohio a few miles above the mouth of the Tennessee. This river runs about 450 miles, and as the current is very gentle, the navigation is easy for sloops as far as Nashville, more than 150 miles from its mouth. It is stated to be navigable for river-boats 150 miles farther up, but in Kentucky the upper course is obstructed by extensive shoals in several places.

Climate.—No meteorological observations made in Tennessee having been published, we are unable to form a precise idea of the climate. It is very probable, as it is assumed by Darby, that the general level of the Mountain Region is about 800 feet more elevated than the level tract on the Mississippi, which is about 300 feet above the sea. This of course must produce a considerable difference in the climate of the two regions. Cornelius found the vegetation in Virginia, east of the Blue Ridge, two weeks earlier than in the valley west of it. It is probable that the winter in the Mountain Region lasts for several weeks, and that the frost is rather severe. In the countries west of the range the rivers are generally covered with ice for a few days in the winter. Snow falls to the depth of ten inches, but seldom lies more than twelve or fifteen days on the ground. In winter and spring a considerable quantity of rain falls; but in the other seasons rain is not frequent, nor does it continue for any length of time. The air in some parts of Tennessee is remarkable for its dryness.

Productions.—The state of agriculture in Tennessee will best be inferred from the statement of the returns of 1840, according to which the quantity of maize grown amounted to 42,467,349 bushels, a quantity much larger than that produced in any other of the United States. As this grain is best adapted for the feeding of hogs, the number of hogs was also larger than in other states, amounting to 2,795,630. Oats were raised to the amount of 6,770,116 bushels; wheat, 4,547,273 bushels; potatoes, 2,373,034 bushels; rye, 297,033 bushels; buckwheat, 6187 bushels; and barley, only 4758 bushels. The quantity of cotton amounted to 128,250,308 lbs., which was not half as much as that produced in Mississippi (289,838,818 lbs.), and little more than half the quantity that was raised in Alabama (240,379,669 lbs.), but nearly as much as was grown in Georgia (148,907,880 lbs.), and Ohio (134,322,755 lbs.). Tobacco was produced to the amount of 26,542,448 lbs., more than one-third of the quantity grown in Virginia (74,157,841 lbs.). Flax and hemp yielded 45,053 tons, and the meadows only 38,512 tons of hay. Rice is little cultivated, as the produce was only 7729 lbs.: the hop plantations yielded only 8401 lbs. The cultivation of the silkworm seems not to have made much progress, as only 11631 lbs. of cocoons were gathered. The value of the produce of the orchards was estimated at 336,767 dollars, which proves that horticulture has made considerable progress. A small quantity of wine was made, amounting to 653 gallons. The sugar made from the sugar-maple amounted to 251,745 lbs. Though the produce of the articles drawn from the forests has decreased, it was still considerable: the lumber was estimated at 2,000,266 dollars, besides 3119 barrels of pitch, tar, turpentine and rosin, and 212 tons of pot and pearl ashes. The number of horses and mules amounted to 327,526, that of neat cattle to 773,390, and that of sheep to 748,459. The value of the poultry was estimated at 581,531 dollars. The produce of the dairy was to the value of 930,603 dollars; the quantity of wool was 1,029,526 lbs.; and the wax 50,715 lbs.

Buffaloes were once numerous, but they have entirely disappeared; the elk and moose-deer are only found

in the Mountain Region, and the deer is still abundant there. There are bears, pumas, wild-cats, and wolves; also beavers, otters, and musk-rats. Racoons, foxes, squirrels, opossums, rabbits, polecats, and minxes are very numerous: pheasants, partridges, pigeons, swans, wild turkeys, ducks, and geese are abundant. There is fish in all the rivers, but not very abundant. The wild trees and plants which yield fruits are the wild plum, the crab-apple, the wild vine, and the strawberry.

There is gold in the mountains bordering on North Carolina, but up to 1834 only 12,000 dollars' worth had been collected. Lead exists in the same mountains, but is not much worked. Iron-ore is found in great abundance on the south side of the Cumberland River, and also at a few other places. Limestone and marble are got in the Cumberland Mountains, and nitre in abundance in some extensive caves near the Mountain Region. Salt-springs are very numerous, and some of them are strong. Some salt is made, but not to a great amount, as salt is easily obtained from the western districts of Pennsylvania and from Ohio.

Population.—In 1838 the Cherokees, who up to that time were in possession of the southern districts of the Mountain Region, left Tennessee, and went to the west of the Mississippi. [North American Indians.] At present the population consists of the descendants of Europeans and of slaves.

By the census of 1820 the population consisted of 422,813 individuals. At the census of 1830 it had increased to 681,904, which gives an increase of 61·3 per cent. in ten years. According to the last census (1840) the population amounted to 829,210, so that in the ten years preceding the census it had increased 21·6 per cent., which is still about double the rate of increase in most countries of Europe. The increase however has not been equal in all parts of the state. In the Eastern District it had risen from 196,301 to 224,259, or about 14·7 per cent.; in the Middle District, from 374,749 to 411,710, or only 9·9 per cent.; and in the Western District, from 110,854 to 193,241, or 74·3 per cent.

In 1830 the population consisted of 535,746 whites, 4555 free coloured people, and 141,603 slaves; and in 1840, of 640,627 whites, 5524 free coloured people, and 183,059 slaves; whence it is evident that the slave population has increased more rapidly than the white, as the increase of the number of slaves amounts to 29·2 per cent. The proportion of the white inhabitants to the slaves is greatest in the Eastern District, which contains only 18,714 slaves and 203,371 whites, so that the slaves constitute only 9·2 per cent. of the number of the whites. In the Middle District there were 301,157 whites and 107,735 slaves, which raises the slave population to 32·4 per cent. of the number of the whites. In the Western District the number of whites amounted to 136,099, and that of the slaves to 56,610, so that the slaves constituted 41·6 per cent. of the white population.

If the population were equally distributed over the state, there would be 20·6 individuals to each square mile. In Scotland there are 90, and in southern Sweden about 42 individuals to each square mile. It is remarkable that the most sterile part of Tennessee, the mountain-region, is the most populous. If we allow it 10,000 square miles, which is probably somewhat too much, it contains 22·4 individuals, whilst the Middle District has only 21·2, and the Western District only 19·3 individuals to each square mile.

Political Divisions and Towns.—For the administration of justice the state is divided into three districts; and for political purposes into seventy-two counties. As Tennessee is eminently an agricultural country, none of the towns have risen to any importance. The capital is Nashville, built on the left bank of the Cumberland River, where the navigation for large boats begins. It is a well-built and thriving place, which in 1830 contained 5565 inhabitants; and in 1840, 6929. Knoxville, on the river Holston, nearly in the centre of the mountain-region, has a population of about 3000. The other towns are small. Murfreesborough, south-east of Nashville, in one of the most populous districts of the state, has about 1500 inhabitants; and Memphis, on the Mississippi, near the boundary-line of the State of Mississippi, is a very thriving town, being a place of resort for the steam-boats which navigate the river.

Manufactures.—Manufacturing industry has not made much progress in Tennessee. In 1840 the number of persons employed in manufactures and trades was only 17,805: of whom 10,409 were in the Middle District; 4679 in the Eastern; and 2727 in the Western. The number of distilleries was 1381, but all on a small scale, as may be inferred from the produce, which amounted only to 1,080,693 gallons: in New York 38 distilleries produced more than 4 millions of gallons, and in Massachusetts 37 distilleries more than 5 millions. Cotton and linen stuffs for clothing are made at home. There is a small number of families who make coarse cotton, linen, and hempen fabrics for sale; and there are also a few paper-mills and manufactures of cordage and ropes. Some bar-iron is made, and nails are manufactured. There are also several small tanneries.

Commerce.—Tennessee is not favourably situated for commerce, as the only river which is navigable for large boats all the year round washes its western extremity. The mountain-region labours under the greatest disadvantages, as the mountains which separate it from the Atlantic regions are difficult to pass. Its commercial wealth consists of live stock: they send their neat cattle to Virginia, and their horses, mules, and hogs to the Carolinas. The Middle and Western Districts are commercially connected with New Orleans, to which place they send, by the Mississippi, cotton, tobacco, maize, pork, potatoes, flour, hemp and flax, deer-skins, lumber, ginseng, and bar-iron. The foreign articles consumed in the country, which consist mostly of grocery and some other articles of manufacture, are imported from Pittsburg and Philadelphia, or from New Orleans.

Education is not neglected. The number of white persons above twenty years of age unable to read and write amounted, in 1840, to 58,532; the number of elementary and common schools was 983, and the number of children attending them 25,090, of which number 6005 were taught at the public expense. The number of academies and grammar-schools was 152, and they were attended by 5548 boys. There are five universities or colleges. The best is the university of Nashville, which has six instructors and a library of about 8500 volumes. Jackson College is near Columbia. The colleges of Greenville, Washington, and Knoxville are smaller. There is a theological seminary at Maryville in East Tennessee for Presbyterian clergymen.

History and Constitution.—The first settlements in Tennessee were made about the middle of the last century, but in 1760 they were destroyed by the Cherokees, then the possessors of this country, from the northern and central part of which they were expelled in 1780. Since that time the number of settlements has continually and rapidly increased. Up to 1790 Tennessee formed a part of North Carolina, but in that year it was ceded by that state to the United States, who converted it into a territory. In 1796 it was admitted into the Union. The legislative power is vested in a general assembly consisting of a senate and a house of representatives, elected by the freeholders for two years. The senate is at present composed of 25 members, and the house of representatives of 75 members. The executive power is vested in a governor, who is chosen by the electors for the term of two years, and is not capable of holding office more than six years out of eight.

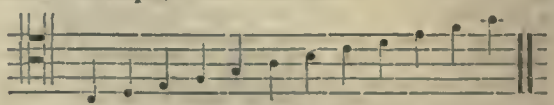
(Cornelius, *Tour in Virginia, Tennessee*, &c.; Long's *Expedition to the Rocky Mountains*, by James; Darby's *Geographical View of the United States;* Pitkin's *Statistical View of the Commerce of the United States; the American Almanack and Repository of Useful Knowledge* for 1842.)

TENNIS, a game in which a ball is driven to and fro by several persons striking it alternately, either with the palm of the hand, naked or covered with a thick glove, or with a small bat called a racket, held in the hand; the aim being to keep the ball in motion as long as possible without allowing it to fall to the ground. Strutt, on the authority of St. Foix, a French author, states that the French game of ball called palm-play, or 'jeu de paume,' was formerly played with the naked hand, then with a glove, which in some instances was lined, and that afterwards the players bound cords and tendons round their hands to make the ball rebound more forcibly; and hence, it is added, the racket derived its origin. He states that palm-play, or hand-tennis, was exceedingly fashionable in

France during the reign of Charles V., it being often played by the nobility for large sums of money. Perhaps the first historical notice of the game in England is that which Shakspere has introduced, almost in the words of the old chroniclers, in his 'Henry V.' (act i., sc. 2), where the dauphin sends a present of tennis-balls in answer to Henry's demand for the sovereignty of France. Henry VII. was a tennis-player; and, as an entry in a MS. register of his expenditure in the thirteenth year of his reign mentions an item of twelve-pence for his loss at tennis and three-pence for the loss of balls, it may be inferred that the game was played abroad, as the loss of balls is not likely to have happened in a tennis-court. Be this as it may, in the sixteenth century tennis-courts were common in England, and the game was very popular with the nobility, which it continued to be down to the reign of Charles II., who frequently diverted himself by playing at tennis with his courtiers. Tennis-courts were divided by a line stretched in the middle, and the players, standing on each side with their rackets in their hands, were required to strike the ball *over* this line. A similar game was sometimes played with a hollow leather ball, inflated with air, and called a *balloon*, which was driven from one player to another by striking with the hand, or with a wooden bracer fixed upon the hand and lower arm. Further particulars respecting these and other games played with a ball may be found in Strutt's 'Sports and Pastimes,' and 'Horda-Angel-Cynnan.'

TENON, JACQUES-RE'NE', an eminent French surgeon, whose father also belonged to the medical profession, was born in 1724. He went to Paris in 1741, where his zeal and talents soon gained him the notice of Winslow, and also of Antoine and Bernard de Jussieu. The first of these celebrated men initiated him in the study of anatomy; the two others developed in him a taste for botany and natural history. In spite of the prejudices and example of his contemporaries, Tenon understood that surgery, far from being separated from the other branches of medical science, and restricted to the mere performance of operations, is on the contrary most strictly united to them. Accordingly from this time he had a wider field opened to him for his professional labours; and he united to the study and treatment of surgical affections minute anatomical investigations and ingenious physiological experiments. In a short time he acquired a well-merited reputation; and though inferior to some other modern French surgeons in skill and genius for that particular department of science, yet few have surpassed him in the extent of his studies and the variety of his information. In 1744 Tenon was appointed an army surgeon of the first class (*chirurgien de première classe aux armées*), and served in the following year throughout the campaign in Flanders. On his return to Paris he obtained by competition (*au concours*) the situation of chief surgeon to the hospital of La Salpetrière, and founded near it a celebrated establishment for inoculation, a practice which his labours contributed much to propagate. He afterwards became a member of the College and of the Royal Academy of Surgery, and succeeded Andouillé as professor of pathology. In 1757 he was received into the Academy of Sciences. Tenon belonged to the first Legislative Assembly, and there displayed the same zealous philanthropy which seemed to belong to all his actions. Upon the re-organization of the learned societies, he became a member of the Institute of the first class, and read in that assembly many interesting papers. He was also a member of the Legion of Honour and of several learned and scientific societies, and preserved to the end of his life the same love of labour and the same zeal for the advancement of science which had marked the early years of his career. He died at Paris, on the 15th of January, 1816, at the advanced age of ninety-two. Few persons have written so many memoirs and monographs as Tenon; many of these have only been published in the annual analysis of the proceedings of the Institute: he is also said to have left behind him a great number of manuscripts. More than thirty of his works are mentioned in the *Biographie Médicale*, of which the following are the most important:—'De Cataracta,' Paris, 1757, 4to. 'Mémoires sur l'Exfoliation des Os,' read before the Academy of Sciences in 1758, 1759, and 1760, and afterwards printed, together with some others, with the title 'Mémoires sur l'Anatomie, la Pathologie, et la Chirurgie,' Paris, 1806, 8vo. 'Mémoire sur les Hopitaux de Paris,' Paris, 1788, 4to.; a very able memoir, which has served as a model for many that have been since written on the same subject, in which are pointed out almost all the improvements that have been introduced into the French hospitals. His last work, which was published when he was ninety years old, is entitled 'Offrande aux Vieillards de quelques Moyens pour prolonger la Vie.'

TENOR, the name of the most common of adult male voices, that which is between the extremes of highest and lowest, or Contratenor [ALTO] and Base. [BASE-VOICE.] The compass of the Tenor is from c, the second space in the base, to G, the second line in the treble. Example, in the tenor clef:—



Hence it will be seen that the tenor and treble are reciprocally at the distance of an octave; consequently, what is calculated for the one voice, as relates to compass, will, at a distance of eight notes, invariably suit the other.

The word is derived from *Teneo, to hold;* for in antient part-compositions, the plain-song, or air, if it may be so denominated, was given to, or *held* by, the Tenor. [CLEF.]

TENOR-CLEF is the C, or mean clef, placed on the fourth line for the use of the tenor-voice. Example:—

It is also occasionally used for the violoncello; and the part of the tenor trombone is written in this clef.

TENOR is also the English name for a larger instrument of the violin kind. See VIOLA.

TENOS (Τῆνος), now Tino, a small island in the Greek Archipelago lying to the south-east of Andros, and between that island and Myconus, and forming one of the group called the Cyclades. S. Nicolo, on its north coast, is in 37° 30′ N. lat. and 25° 15′ E. long. It is about 15 miles long, and its greatest length is from north-west to south-east. It was anciently called Hydrussa, because it was well watered (*καταῤῥυτον*) (Steph. Byzant., v. *τῆνος*; Pliny, *Hist. Nat.*, iv. 12); and Ophiusa (Strabo, p. 487, ed. Casaub.), because it abounded in snakes. In the time of the Persian invasion of Greece a Tenian trireme rendered good service to the Greeks by deserting from the enemy, and giving intelligence of their movements immediately before the battle of Salamis (B.C. 480). The name of the Tenians was in consequence inserted upon the tripod at Delphi in the list of states to whom Greece was indebted for the repulse of the invader. (Herod., viii. 82.) According to Pausanias (v. 23) the Tenians were among those whose names were inscribed on the statue of Jupiter at Olympia, dedicated by the Greeks who fought at Platæa. The island paid tribute to Athens during the Peloponnesian war. (Thucyd., vii. 57.) It was taken, and the inhabitants enslaved by Alexander, tyrant of Pheræ, B.C. 362. (Demosthen. *in Polycl.*, 1207, Reiske; Clinton, *Fasti Hellen.*, a. 362.) In the reign of Tiberius, when the Roman senate instituted an inquiry into the rights and privileges attached to temples in the provinces of the empire, the Tenians quoted an oracle of Apollo, by which they had been commanded to consecrate a statue and temple to Neptune. (Tacitus, *Annal.*, iii. 63.) This temple was of considerable size, as appears from Strabo (p. 487), and on the coins of Tenos the trident of Neptune is a common type; on the reverse there is usually a bunch of grapes. The island is still celebrated for its wine, of which about twenty sorts are grown.

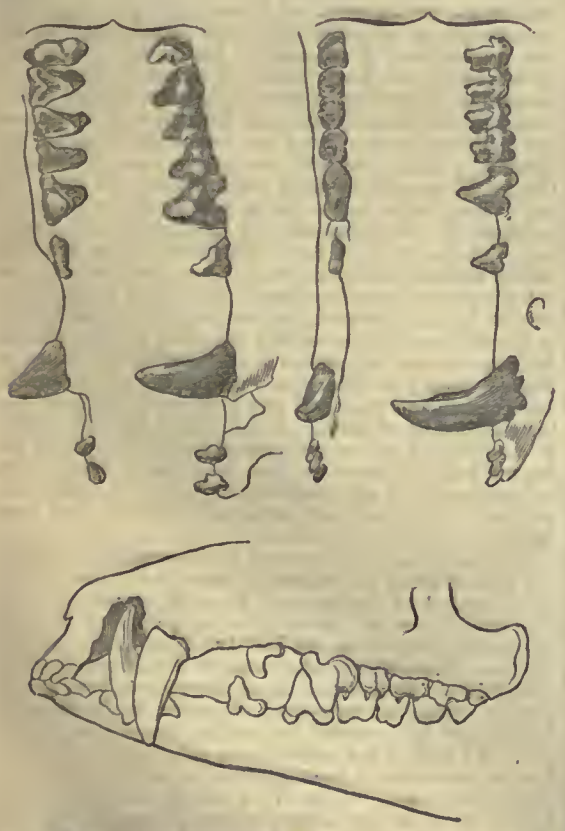
TENREC. *Centetes*, Ill.; *Centenes*, Desm.; *Setiger*, Geoff. The Tenrecs may be considered—indeed they have been considered by most zoologists—as Hedgehogs without the power of rolling themselves up into a ball. They were not included in the genus *Erinaceus* of Linnæus, as he left it, in his last edition of the *Systema Naturæ* (the 12th), but in the 13th (Gmelin's) all the known species were included under that genus. They have no tail, are nocturnal for the most part in their habits, feed on insects, lie dormant during a considerable portion of the year, and that during the hot season, and have the skin beset with spines or spine-like bristles.

It is in this genus that we first find the jugal bone wanting among the Insectivora.

Geographical Distribution and Habits of the Genus.—Cuvier remarks that three species are found in Madagascar, the first of which, the *Tenrec*, properly so called, *Centetes ecaudatus* (*Erinaceus ecaudatus*, Gmel.) is, he observes, naturalized at the Isle of France.

Mr. Swainson (*Classification of Quadrupeds*) states that the second division of the family SORECIDÆ is composed of mole-like animals, apparently connected to the Shrews by the American *Scalops* and the African *Chrysochloris*, and that it includes but three genera. [SORECIDÆ, vol. xxii., p. 261.] Of the Tenrecs (or Tendrics as he writes the word) he treats as animals peculiar to Madagascar, apparently as capable of domestication as their European congeners. 'Although inhabiting a warm region,' proceeds Mr. Swainson, 'they are said to pass the three warmest months of the year in a state of torpidity: this, it must be owned, is a singular circumstance, and is the only one upon record of an animal hybernating, so to speak, in the height of summer. In other respects they feed like the European Hedgehog, and are nocturnal animals.' The singularity of the circumstance vanishes when we find that the period in which the Tenrec becomes dormant is not only the warm season, but the dry season, and the apparent anomaly becomes another instance of the harmony of adaptation which prevails throughout nature. A suspension of the active powers of life becomes absolutely necessary to insectivorous quadrupeds, because there must be certain seasons when they would find no food. Our usual term for the act of retiring, in order to give way to this suspension, is hybernation; because, in our latitudes, this abstraction of worms and insects takes place in winter, when our Bats, Hedgehogs, and Shrews lay themselves up till spring returns to call forth their prey. But in Madagascar the dry season is that in which the absence of worms and insects occurs; and then it is that the Tenrec sinks into its half living and half dead state.

Dental Formula:—Incisors $\frac{6}{6}$; canines $\frac{1-1}{1-1}$; molars $\frac{6-6}{6-6}$: =40.



Teeth of Tenrec, one-third larger than the natural size. (*F. Cuv.*)

The situation assigned by Cuvier to the Tenrecs is between the Hedgehogs (*Erinaceus*, Linn.) and *Cladobates*. [TUPAIA.]

Cuvier remarks that the muzzle of the Tenrecs is very pointed, and that their teeth are very different from those of the Hedgehogs.

Generic Character.—Body spiny; not capable of being rolled up into a ball, as in the Hedgehogs; muzzle elongated; five toes on each foot, separated and armed with crooked claws.

Examples.—The species are called Tenrec and Tendrac; but the latter name is confusedly applied to at least two species.

Of the first, the *Centetes ecaudatus*, Ill., is the largest, exceeding our Hedgehog in size. It is covered above with long flexible spines, except on the vertex and occiput, and has no coloured bands: the under part of the body is clothed with hairs or bristles only, which are yellowish, mixed with some longer black ones. Baron Cuvier, who is followed by Lesson, states, in his last edition of the *Règne Animal*, that this species has only four incisors in the lower jaw; but M. F. Cuvier, who makes the number six in each jaw, says that his illustration is taken from *Cent. ecaudatus* and *Cent. setosus;* and Fischer gives the same number.

Centetes ecaudatus.

Centetes setosus, Ill.—The *Tendrac* of Buffon and Zimmerman—is less than the former, and the spines are short and rigid.

Tendrac.

The *Centetes semispinosus* is still less, and hardly so large as a common mole. Its body is clothed with a mixture of spines and bristles, and is banded longitudinally with yellow and black.

Striped Tenrec.

TENSION (Mechanics), the name given to the force by which a bar or string is pulled, when forming part of any system in equilibrium or in motion. Thus when a weight is supported by a string, the tension of the string is the weight which is suspended to it. Every point of the string may be considered as a point of application of two equal and opposite forces, downwards and upwards, each equal to the weight applied.

TENTERDEN. [Kent.]

TENTERDEN, CHARLES ABBOTT, LORD, born at Canterbury, on the 7th of October, 1762, was the son of a barber, who has been described as 'a tall, erect, primitive-looking man, with a large club pigtail, going about with the instruments of his business, and attended frequently by his son Charles, a youth as decent, grave, and primitive-looking as himself.' He was entered in 1769 on the foundation of the king's school of the cathedral, under Dr. Osmund Beauvoir, who is stated by Sir Egerton Brydges to have been an admirable classical scholar, of fine taste, and some genius. Sir Egerton, who for some years held the place next to Abbott in the class, speaks of him as remarkable even in his school-boy days for accuracy, steadiness, and equality of labour; as well acquainted with the rules of grammar, sure in any examination or task, and a tolerably correct writer of Latin verses and prose themes.

In the beginning of 1781 Abbott was elected scholar of Corpus Christi College, Oxford, with an allowance, including his exhibition, of 50*l.* a year. His mathematical acquirements are said by his friends to have been considerable. In 1784 he obtained the chancellor's medal for the best Latin verses on Lunardi's balloon, 'Globus Aerostaticus;' in 1786 his essay 'On the Use and Abuse of Satire,' obtained the chancellor's medal for the English essay. This essay displays the turn for neat, lucid, and exhaustive arrangement, which was the most marked feature of his matured intellect, and also a good deal of that want of passion and imagination which, perhaps as much as any of his positive qualities, contributed to his judicial eminence. He was elected a fellow of his college, and appointed junior tutor to Mr. (afterwards bishop) Burgess.

By the advice of Mr. Justice Buller, whose son was one of his private pupils, Abbott entered himself of the Inner Temple in 1788. He also, in compliance with the suggestion of the same experienced lawyer, attended some months the office of the London solicitors Messrs. Sandys and Co. He afterwards became a pupil of Mr. (subsequently Baron) Wood; and, aided by his recommendation, began to practise as a special pleader with marked success. He was called to the bar in Trinity term, 1795.

He married, on the 13th of July, 1795, Mary, eldest daughter of John Logier Lamotte, Esq., a gentleman of fortune in Kent. It is said that when the father hinted at the expediency of a marriage-settlement, Abbott said he had nothing but an excellent law-library, which the lawyers might tie up as tightly as they pleased.

Having selected the Oxford circuit, he speedily rose into great business. The jealousy of his young rivals gave rise to rumours of his being too courteous to attorneys; but by whatever means he may have obtained his position, he kept it by the preference the leaders evinced for a junior who could often suggest a case in point, and was master of all the technicalities of pleading. To this he owed his appointment, by Sir Vicary Gibbs, when solicitor-general, to the office known among the members of the bar by the name of treasury-devil, the junior counsel to whose care the business of government is intrusted. In this character he took part in most of the numerous state-trials which occurred about the close of last century. As his character became established, he was appointed standing counsel to the Bank and other great mercantile communities. When the returns of the income-tax were called for, Mr. Abbott's account was looked upon as a curiosity, both for its minute accuracy and for the largeness of the sum-total of his fees during the past year —8026*l.* 5*s.*

In a sketch of Lord Tenterden, which appeared in the sixty-ninth volume of the 'Edinburgh Review,' Lord Brougham says of his career at the bar:—'As a leader he very rarely, and by some extraordinary accident only, appeared; and this in a manner so little satisfactory to himself, that he peremptorily declined it whenever refusal was possible; and he seemed to have no notion of a leader's duty beyond exposing the pleadings and the law of the case to the jury, who could not comprehend them with all his explanation. His legal arguments, of which for many years the books are full, were extremely good, without reaching any very high pitch of excellence; they were quite clear, abundantly full of case law; betokening some dread of grappling with principle, and displaying none of the felicitous commentary that marked Mr. Holroyd's.'

In 1802 Mr. Abbott published his 'Treatise of the Law relative to Merchant-Ships and Seamen.' This work has gone through many editions: it exhausts the subject, is well arranged, and well written: its merits have been repeatedly acknowledged: it is one of the best English law treatises.

In 1808 Mr. Abbott was offered a seat on the bench, but declined from prudential motives, his professional income far exceeding the salary of a judge. As years grew upon him however, and his fortune increased, he began to long for the comparative repose of the bench. In February, 1816, he was offered a seat as puisne judge in the Court of Common Pleas, and accepted it. In May of the same year, on the death of Mr. Justice Le Blanc, he yielded to the importunity of Lord Ellenborough, and was chosen to supply the vacancy in the Court of King's Bench, and was knighted about the same time. On the 4th of November, 1818, Sir Charles Abbott succeeded Lord Ellenborough as chief-justice of that court.

It has been alleged that at the outset of his judicial career chief-justice Abbott was apt to lose himself among the minute details of the cases which were brought before him. It is allowed at the same time that during the last seven or eight years of his time he took broader and more comprehensive views of questions, and displayed great judicial capacity. He had learned to deal with facts, and his law was, as it always had been, safe, accurate, and ready. His statements and decisions were clothed in correct, succinct, and appropriate language. He was averse to over-curious subtleties; loved to overrule technical objections both in civil and criminal pleadings; and showed great anxiety to make his decisions accord with common sense and substantial justice. Perhaps he shone most in the management of arguments which required a combination of scientific with legal knowledge: 'to see him preside over a complicated patent case was a very great treat, whether to a lawyer or a man of science.' A reasonable distinction, a reasonable interpretation of the law, were his favourite phrases. He was, as every learned and judicious lawyer must be, rather impatient of the cheek of a jury; and was not always able to keep his temper in command when arguing with the bar. His impartiality, as far as the parties were concerned, was unquestioned. 'It was an edifying sight,' says Lord Brougham, 'to observe Lord Tenterden, whose temper had been visibly affected during the trial (for on the bench he had not always that entire command of it which we have described him as possessing at the bar), addressing himself to the points in the cause with the same perfect calmness and indifference with which a mathematician pursues an abstract truth; as if there were neither the parties nor the advocates in existence, and only bent on the discovery and the elucidation of truth.' Chief-Justice Abbott's anxiety to support the executive authority on all occasions was beyond a doubt excessive; but this appears to have been the consequence of temperament and very early associations: it shows itself even in his prize essay upon Satire.

Sir Charles Abbott was raised to the peerage in 1827, by the title of Baron Tenterden. He made a successful début as a speaker in the House of Lords in support of Miss Turner's divorce bill; he pertinaciously opposed the passing of the Corporation and Test Act Repeal Bill; and was the most impressive speaker against the Roman Catholic Relief Bill. His judicial labours rendered him for the next two years an unfrequent attendant in the House of Lords; but he recorded his protest against the Reform Bill. He took at the same time an active part in the business of legislation. Among his well-studied and carefully prepared acts are—9 Geo. IV., c. 14, for the alteration of the law as to the limitation of actions of account and upon the case; 9 Geo. IV., c. 15, to prevent a failure of justice by reason of variances between records and writings pro-

duced in evidence; 1 Will. IV., c. 21, Mandamus and Prohibition Acts; 1 Will. IV., c. 22, Interrogatories Act; 1 & 2 Will. IV., c. 58, Interpleader Act; 2 & 3 Will. IV., c. 39, Uniformity of Process Act; 2 & 3 Will. IV., c. 71, Prescription Acts; and (prepared under his sanction) 3 & 4 Will. IV., c. 27, for the limitation of actions and suits relating to real property, and for simplifying the remedies for trying the rights thereto.

As his political opinions were of the kind generally understood to predominate at Oxford, so his literary tastes retained the impress of his University education. When Sir James Scarlett, on the trial of Mr. Hunt for the publication of 'The Vision of Judgment,' alluded to the poetry of Lord Byron as familiar to the jury, Lord Tenterden could not repress the observation that, for himself, 'he was bred in too severe a school of taste to admire the modern poets.' His favourite recreations during the long vacation were the perusal of the classics, the study of botany, and the composition of Latin verses on flowers and plants. He founded and endowed, in the grammar-school of his native city, two annual prizes; the one for the best English essay, the other for the best Latin verse. In his relaxations, as in the discharge of his public duties, he displayed a mind narrow, it may be, and unimpassioned, but active, dexterous, and elegant.

His later years were overclouded with ill-health, and alarm occasioned by the aspect of public affairs. He continued however to discharge assiduously the duties of his high office. He presided for the two first days at the trial of the mayor of Bristol for misconduct during the riots in that city at the time of the Reform Bill, but on the third he was confined to bed by a violent attack of inflammation. The disease baffled the skill of his physicians, and he expired on the morning of Sunday, November 4, 1832. Lady Tenterden died on the 19th of December following. He had two sons, one of whom succeeded him in the title, and two daughters.

(The materials for this article have been found in a notice of Lord Tenterden in the Obituary of *The Gentleman's Magazine* for December, 1832; in a 'Life of Lord Tenterden' which appeared in the 26th volume of *The Law Magazine*, pp. 51-87; in a sketch of the 'Judicial Character of Lord Tenterden' by Mr. Sergeant Talfourd, in the 9th volume of the same work, pp. 234-6; and in a sketch of his career and character by Lord Brougham in the 76th volume of the *Edinburgh Review*, pp. 14-23. There is a portrait of Lord Tenterden taken by Owen in 1819, and engraved in mezzotinto in a quarto form by S. W. Reynolds, and another by C. Penny engraved by H. Meyer. A cast for a bust was taken from his countenance after death.)

TENTHREDO, a genus of Hymenopterous insects of the section *Terebrantia*. The genus *Tenthredo* of Linnæus is in modern systems regarded as constituting a family, to which the name *Securifera* has been applied by Latreille, and *Tenthredinidæ* by Leach.

Latreille restricts the generic term *Tenthredo* to those species which have nine joints to the antennæ, and in which these organs are not distinctly thickened at the apex. Their larvæ have from eighteen to twenty-two feet. The genus *Tenthredo* is however still further restricted by many other authors, and it is especially to Dr. Leach (*Zoological Miscellany*, vol. iii.) that we are indebted for pointing out distinguishing characters for the subdivisions of the very extensive Linnean genus. By this author the *Tenthredinidæ* are divided chiefly according to the structure of the antennæ, and the cells enclosed by the nervures of the wings. The first section, according to Dr. Leach, contains those species which have the antennæ short and clubbed at the extremity and the third joint long; the superior wings with two marginal and three submarginal cells. It includes the genera *Cimbex*, *Trichiosoma*, *Clavellaria*, *Zarea*, *Abia*, &c.

The species of the second section have the antennæ of moderate length, filiform, and composed of three joints; the last joint long, slightly thickened at the extremity, and in the males ciliated, and sometimes forked. It contains the genera *Hylotoma* and *Schizocerus*. The characters of the third section are—antennæ short, with nine or ten joints, increasing in thickness in the middle, but ending in a point; the third joint longer than the fourth; body short and increasing in thickness towards the apex. Genera: *Messa*, *Selandria*, and *Fenusa*.

Section 4.—Antennæ composed of nine joints, moderately long; body moderately long; upper wings with two marginal cells. To this section belongs the genus *Tenthredo* as at present restricted; it is distinguished by the upper wings having four submarginal cells, and the antennæ with the third and fourth joints of equal length. The genus *Allantus* differs only from *Tenthredo* in having the third joint of the antennæ longer than the fourth. The *Allantus scrophulariæ* is a very common species in this country, and is found on the scrophulariæ, on the leaves of which its larvæ feed. The perfect insect somewhat resembles a wasp, but is of a rather more slender form; it is black, and has the body adorned with yellow rings; the legs (with the exception of the thighs) and antennæ are also yellow. The larva, which is provided with twenty-two feet, is white and has black dots, and the head is black. When touched it rolls itself up in a spiral manner, as indeed do the larvæ of other *Tenthredinidæ*.

Section 5.—Superior wings with but one marginal cell; body short, narrower at the extremity in the males; antennæ simple, nine-jointed, slightly ciliated, increasing in thickness in the middle, and decreasing at the extremity. This section contains the genera *Crœsus*, *Nematus*, and *Cladius*, examples of each of which are found in this country.

Section 6.—Antennæ with numerous joints; body rather depressed; wings with two marginal and four submarginal cells. British genera *Tarpa*, *Lyda*, and *Lophyrus*. The larvæ of the species of *Lophyrus* live in society, more particularly on the pines, and are said to be very injurious to the young plants. The species of this genus are very rare in England. The antennæ are serrated in females, and in the males they are provided with a double series of denticulations.

TENTHS are the tenth part of the yearly value of all ecclesiastical livings. They were formerly claimed by the pope as due to himself by divine right, after the example of the Jewish high-priest who had of the Levites a tenth-part of the tithes; and his claim was sanctioned, in this country, by an ordinance in the 20th year of Edward I., when a valuation of all livings was made, in order that the pope might know the amount of his revenue from this source. The possessions afterwards acquired by the church were not liable to the payment of tenths to the pope, as all livings continued to be charged according to that valuation. (Coke, 2 *Inst.*, 627.) When the authority of the pope was extinguished at the Reformation, Henry VIII. transferred the revenue arising from tenths to the crown, and had a new valuation of all the livings, so as to obtain the tenth of their true yearly value at that time. (26 Hen. VIII., c. 3, s. 9-11.) By royal grants under 1 Eliz., c. 19, s. 2, the Archbishop of Canterbury and the Bishop of London were exempted from tenths and were also authorized to receive the tenths of several benefices as a compensation for certain estates which were alienated from their sees. By the 6 Anne, c. 24, all benefices were discharged from the payment of tenths which, at that time, were under the annual value of 50*l.*, except those of which the tenths had previously been granted by the crown to other parties. There are also some other special exemptions. At the present time, out of 10,498 benefices, with and without cure of souls, there are 4898 which remain liable to tenths. (*Parl. Rep. First-Fruits and Tenths*, 1837, No. 384.) Queen Anne gave up the revenue arising from tenths, as well as from first-fruits, which had been enjoyed by her predecessors since the Reformation, and by act 2 and 3 of her reign, c. 11, assigned it to the augmentation of poor livings; for which purpose she erected a corporation by letters patent in 1704 to administer the funds, called the Governors of Queen Anne's Bounty. This act declared that Episcopal sees and livings not exempted should continue to pay in such rates and proportions only as heretofore, or according to the valuation of Henry VIII., commonly known as the 'King's Books.' Tenths under the act 1 Vict., c. 20, are collected by the Treasurer of the Governors of Queen Anne's Bounty. Payment is enforced by Exchequer process, when not duly made, and the treasurer is required to give notice of arrears within one month after the proper time of payment. In case of a living being vacated, the Exchequer is empowered by act 26 Hen. VIII., c. 3, s. 18, to recover arrears of tenths, not only from the executors and administrators, but also from the successor of the last incumbent. (2 Burn's *Ecclesiastical Law*, 9th ed., pp. 273-295.) [First-Fruits; Taxatio Ecclesiastica; Tithes.]

TENTZEL, or TENZEL, WILHELM ERNEST, a German historian and antiquarian, was born in 1659, at Greussen in Thuringia, where his father was pastor. After the completion of his school education he went, at the age of eighteen, to the university of Wittenberg, where he chiefly devoted himself to the study of the antient and Oriental languages in connection with history. In 1683 he was appointed teacher at the gymnasium of Gotha, and was at the same time intrusted with the care of the collection of antiquities and coins belonging to the Duke of Saxe-Gotha. Several learned dissertations which he published shortly after this time attracted the attention of his learned countrymen, in consequence of which he became a very active contributor to the 'Acta Eruditorum,' and to the 'Observationes Hallenses.' Tentzel was the first German who conceived the idea of establishing a German journal for reviewing new books and for publishing interesting essays. This periodical was set on foot in 1689, under the title 'Monatliche Unterredungen einiger guten Freunde von allerhand Büchern und andern annehmlichen Geschichten.' The undertaking had great success, and was carried on till 1698. The whole was published in monthly parts, and consists of ten volumes. The extensive knowledge of history, especially of the history and antiquities of Germany, procured Tentzel, in 1696, the honourable post of historiographer to the house of Saxony of the Ernestine line. Before he commenced writing on the history of Saxony he travelled through the greater part of Germany, visiting several courts and examining various libraries to find materials. In 1702 the elector of Saxony (also king of Poland) conferred upon Tentzel the title of councillor, and made him historiographer of the electorate. In this capacity Tentzel took up his residence at Dresden, and was frequently obliged to appear at court. But the simple honesty and straightforwardness of the man made him a subject for ridicule among the ignorant and idle courtiers, and as soon as Tentzel became aware of it he resigned his office and retired to private life, devoting himself entirely to his historical and antiquarian studies. He died on the 24th of November, 1707, in great poverty.

Besides the numerous essays in the periodical publications mentioned above, the following separate works of Tentzel deserve to be mentioned: 'De Ritu Lectionum Sacrarum,' Wittenberg, 1685, 4to.; 'Exercitationes Selectæ, in duas partes distributæ,' Leipzig, 1692, 4to.; 'Epistola de Sceleto Elephantino Tonnæ nuper effosso,' Gotha and Jena, 1699, 12mo.: 'Von dem Alter der Buchdruckerkunst,' Gotha, 1700, 12mo.; this interesting work is translated into Latin and incorporated in Wolf's 'Monumenta Typographica,' ii. 644, &c. The principal work of Tentzel is his 'Saxonia Numismatica, sive Nummophylacium Numismatum Mnemonicorum et Iconicorum à Ducibus Saxoniæ eudi jussorum,' Frankfort, 1705, 2 parts in 4to. He also continued the history of Gotha which had been commenced by Caspar Sagittarius, in two supplementary volumes. His history of the Reformation, 'Historischer Bericht vom Anfang und Fortgang der Reformation,' which was edited by E. S. Cyprian, in 2 vols. 4to., Leipzig, 1718, is a valuable work, which should still be consulted by the student of that important period.

(Jöcher, *Allgem. Gelehrten-Lexicon*, iv., p. 1057, &c.; *Conversations-Lexicon*, s. v. 'Tenzel.')

TENUIPE'DES, Lamarck's second division of the *Conchifera Dimyaria*, consisting of the *Maetracea*, *Corbulacea*, the *Lithophaga* (*Saxicola*, *Petricola*, and *Venerupis*), the *Nymphacea*, the *Cardiacea*, the *Trigonacea*, the *Naiades*, and the *Chamacea*.

In the first division, *Crassipèdes*, are comprised the *Tubicolèes*, the *Solenacea*, and the *Myaria*.

M. Deshayes, in the last edition of Lamarck, objects, and we think with reason, to these divisions as being defective; nor does he consider the arrangement capable of amelioration, because the principal character is too exclusive. He observes that to follow it rigorously it would be necessary to break very natural links which bind certain genera together.

TENUIROSTRES. Cuvier made the *Tenuirostres* the fourth family of his *Passereaux*, placing it between the *Conirostres* and the *Syndactyles*, and comprising under it the genera *Sitta*, Linn. (with the subgenera *Xenops*, Ill.; *Anabates*, Temm.; and *Synallaxis*, Vieill.); *Certhia*, Linn. (with the subgenera *Certhia*, Cuv.; *Dendrocolaptes*, Herm.; *Tichodroma*, Ill.; *Nectarinia*, Ill.; *Dicæum*, Cuv.; *Melithreptus*, Vieill.; *Cinnyris*, Cuv.; and *Arachnathera*, Temm.); *Trochilus*, Linn. (dividing the genus into the Humming-birds properly so called, or *Colibris*, *Trochilus*, Lacép.; and the *Oiseaux Mouches*, or Fly-birds, *Orthorhynchus*, Lacép.); *Upupa*, Linn. (with the subgenera *Fregilus*, Cuv.; the Hoopoes properly so called *Upupa*; *Promerops*; and *Epimachus*).

Mr. Vigors, after pointing out the place of one group of the Linnæan *Certhiæ* which climb and feed on animal food among the Scansores, and that of the other group which live only on the nectar of flowers, and have feet formed for perching only [Creeper, vol. viii., p. 146], thus enters the family now before us, and designates the *Suctorial Birds* as the most interesting group perhaps of the animal world. [Sunbirds, vol. xxiii., p. 284.] He remarks that the aberrant families of the order are so numerous in their forms, and hitherto have been so unsatisfactorily characterized, that it is impossible to speak of them with that certainty which may attend observations on better defined groups. The genus *Promerops* appears to him to be that form of the present tribe which approaches nearest to the adjoining tribe of Fissirostres. Retaining, Mr. Vigors observes, the slender bill of the *Tenuirostres*, *Promerops* exhibits somewhat of the broad base of the bill of the *Fissirostres*, and, at the same time, the gressorial feet. By means of *Merops*, he remarks, the curved bill of which approaches the structure of its own, it appears to be immediately connected with that group. 'Of the limits of this family, which may receive its appellation from M. Brisson's above-mentioned genus,' continues Mr. Vigors, 'I can say nothing at present; nor do I wish to enter into more than a general reference to the succeeding family of *Meliphagidæ*.' (See the article for this.)

The families admitted by Mr. Vigors into this tribe of Insessores will be found in the article Sunbirds, *loc. cit.*

Mr. Swainson (to whose publication on this order, in the 1st vol. of the 'Zoological Journal,' which appeared after the paper *On the Natural Affinities that connect the Orders and Families of Birds* was sent to press, Mr. Vigors refers), in his tenth chapter of the second volume of the 'Classification of Birds,' remarks, that the most aberrant division of the insessorial order is that of the *Tenuirostres*, or honeysuckers, so called from the great majority deriving their subsistence both from insects and the nectar of plants, which they suck up by means of a long or filamentous tongue adapted for the purpose. 'As these birds,' says Mr. Swainson in continuation, 'are furthest removed from the types of their order, they consequently show a greater affinity to the *Scansores* on one hand, and to the *Fissirostres* on the other, than to the more perfect groups of the perchers, as seen in the *Dentirostres* and *Conirostres*: like the scansorial creepers, the bill is slender, and the feet very short; but there the comparison ceases. The scansorial birds derive their food entirely from insects; and, in general, have a simple and pointed tongue; but those we are now to consider are chiefly supported by vegetable juices, extracted by means of a very long tongue, always retractile, and either simply forked, or divided into so many slender filaments as to resemble a painter's brush; the bill moreover is so soft or delicate, that it is often incapable of grasping food, and appears, in the typical groups, principally intended to protect the tongue, as the chief member by which life is supported.'

Mr. Swainson includes the following families under this tribe:—Meliphagidæ; *Cinnyridæ* [Sunbirds]; Trochilidæ (Humming-Birds); Promeropidæ (Hoopoes); and *Paradisiadæ* [Birds of Paradise].

The *Tenuirostres* are placed by this author between the Scansores and the Fissirostres.

M. Lesson makes the tribe *Tenuirostres* (which he arranges between the *Latirostres* and the *Syndactyles*) consist of the following families and genera:—

1. Promeropidæ.

Genera.—*Upupa*; *Promerops*.

2. Certhindæ.

Genera.—*Certhia*; *Tichodroma*; *Dendrocolaptes*; *Climacteris*; *Furnarius*; *Cæreba*; *Dicæum*.

3. Philedonidæ.

Genera.—*Drepanis*; *Cinnyris*; *Pomatorhinus*; *Prinia*; *Orthotomus*; *Myzomela*; *Myzantha*; *Anthochæra*, *Tropidorhynchus*; *Meliisuga*.

4. Trochilidæ.

Genera.—*Polytmus*, Briss.; *Ornismya*, Less.

In Mr. G. R. Gray's 'List of the Genera of Birds' (2nd edit., 1841), a work remarkable for its accuracy and the quantity of condensed labour which it contains, the *Tenuirostres* stand as the second tribe of Insessores, between the *Fissirostres* and the *Dentirostres*, and comprise the following families, subfamilies, and genera:—

1. Upupidæ. (See the article.)
2. Nectarinidæ. [Sunbirds.]
3. Trochilidæ. (See the article.)
4. Meliphagidæ.

Subfamily 1. *Myzomelinæ*.

Genera.—*Myzomela*, Vig. and Horsf. (*Phylidonyris*, Less.; *Certhia*, Gm.; *Meliphaga*, Vig. and Horsf.): *Acanthorhynchus*, Gould (*Leptoglossus*, Sw.; *Melithreptus*, Vieill.; *Certhia*, Lath.; *Meliphaga*, Vig. and Horsf.): *Glyciphila*, Sw. (*Meliphaga*, Lew.).

Subfamily 2. *Meliphaginæ*.

Genera.—*Meliornis*, G. R. Gray (*Certhia*, Lath.; *Meliphaga*, Lew.; *Philedon*, Cuv.; *Strigiceps?* Less.): *Prosthemadera*, G. R. Gray (*Merops*, Lath.; *Authochæra*, Vig. and Horsf.; *Philemon*, Vieill.; *Sturnus*, Daud.; *Meliphaga*, Temm.; *Philedon*, Cuv.): *Ptilotis*, Sw. (*Meliphaga*, Lew.; *Philemon*, Vieill.; *Certhia*, Lath.): *Authornis*, G. R. Gray (*Anthomyza*, Sw.; *Melithreptus*, Vieill.; *Furnarius*, Steph.; *Certhia*, Sparr.; *Philedon*, Less.): *Philemon*, Vieill. (*Anthochæra*, Vig. and Horsf.; *Merops*, Gm.; *Meliphaga*, Temm.; *Philedon*, Cuv.): *Phyllornis*, Boie (*Turdus*, Gm.; *Chloropsis*, Jard. and Selby; *Meliphaga*, Horsf.): *Meliphuga*, Lew. (*Zunthomyzu*, Sw.; *Merops*, Lath.; *Philemon*, Vieill.; *Anthochæra*, Vig. and Horsf.; *Xanthomyzu*, Strickl.; *Philedon*, Cuv.): *Anthochæra*, Vig. and Horsf. (*Creadion*, Vieill.; *Philedon*, Cuv.; *Merops*, Lath.): *Acanthogenys*, Gould (*Anthochæra*, Fras.): *Entomyza*, Sw. (*Gracula*, Lath.; *Philemon*, Vieill.; *Gymnops*, Cuv.; *Entomyzon*, Sw.; *Tropidorhynchus*, Vig. and Horsf.; *Meliphuga* (Lew.), Temm.): *Tropidorhynchus*, Vig. and Horsf. (*Philedon*, Cuv.; *Merops*, Lath.; *Meliphuga*, Temm.; *Gymnops*, Cuv.).

Subfamily 3. Melithreptinæ.

Genera:—*Plectorhamphus*, G. R. Gray (*Plectorhyncha*, Gould): *Manorhina*, Vieill. (*Myzantha*, V. and H.; *Philanthus*, Less.; *Gracula*, Lath.): *Psophodes*, V. and H. (*Muscicapa*, Lath.; *Timaliu*, ? Sw.): *Eidopsarus*, Sw. (*Sturnus*, Wagl.): *Melithreptus*, Vieill. (Hæmatops, Gould; *Gymnophrys*, Sw.; *Meliphaga*, Temm.; *Philedon*, Cuv.; *Meliphuga*, V. and H.; *Certhia*, Shaw): *Entomophila*, Gould.

5 Certhidæ.

Subfamily 1.

Genera:—*Cinclodes*, G. R. Gray (*Furnarius*, Less.; *Opetiorhynchus* (Temm.), Gould and G. R. Gray; *Upucerthia*, D'Orb.; *Motacilla*, Gm.): *Upucerthia*, J. Geoffr.: *Furnarius*, Vieill. (*Opetiorhynchus*, Temm.; *Figulus*, Spix; *Merops*, Gm.; *Turdus*, Licht.): *Geositta*, Sw. (*Certhilauda*, D'Orb.; *Furnarius*, G. R. Gray; *Alauda*, Kittl.): *Lochmias*, Sw. (*Picerthia*, J. Geoffr.): *Enicornis*, G. R. Gray (*Eremobius*, Gould): *Ochetorhynchus*, Meyen (*Upucerthia?* D'Orb. et Lafr.): *Limnornis*, Gould: *Sclerurus*, Sw.: *Cinclocerthia*, G. R. Gray (*Stenorhynchus*, Gould).

Subfamily 2. Anabitanæ.

Genera:—*Synallaxis*, Vieill. (*Sphenuru*, Licht.; *Purulus*, Spix; *Synallaxis*, D'Orb. et Lafr.): *Diglossa*, Wagl. (*Serrirostrum*, D'Orb. et Lafr.; *Dendroma*, Sw.; *Agrilorhynchus*, Bonap.; *Uncirostrum*, D'Orb. et Lafr.): *Anumbius*, D'Orb. et Lafr. (*Annumbi*, Azara; *Furnarius*, Vieill.; *Sphenura*, Licht.; *Mulurus*, Sw.; *Anabutes*, Spix; *Anthus*, Less.; *Synallaxis*, Gould): *Anabates*, Temm. (*Philydor*, Spix; *Sphenura*, Licht.; *Motacillu*, Gm.; *Xenops*, Lafr.): *Oxyrhamphus*, Strickl. (*Oxyrhynchus*, Temm.; *Oxyruncus* (olim), Temm.).

Subfamily 3. Dendrocolaptinæ.

Genera:—*Dendroplex*, Sw. (*Nasica*, Less.; *Oriolus*, Gm.; *Dendrocoluptes*, Cuv. and Temm.): *Glyphorhynchus*, Pr. Max. (*Sphenorhynchus* (olim), Pr. Max.; *Dendrocolaptes*, Licht.; *Sittucillu*, Less.; *Zenophasia*, Sw.; *Xenophasia*, Strickl.): *Dendrocops*, Sw. (*Dendrocolaptes*, Spix): *Dendrocincla*, G. R. Gray (*Dryocopus*, Pr. Max.; *Dendrocolaptes*, Licht.): *Dendrocolaptes*, Herm. (*Dendrocopus*, Vieill.; *Gruculu*, Gm.): *Xiphorhynchus*, Sw. (*Dendrocolaptes*, Temm., Cuv.; *Picoluptes*, Less.; *Dendrocopus*, Vieill.): *Proluptes*, Less. (*Ziphorhynchus*, Sw.; *Dendrocolaptes*, Spix; *Oxyurus*, Less.; *Dendroplex*, Sw.): *Sittasomus*, Sw. (*Neops*, Vieill.; *Synallaxis*, Cuv.; *Dendrocolaptes*, Temm.).

Subfamily 4. Certhinæ.

Genera:—*Certhia*, Linn.: *Oxyurus*, Sw. (*Synallaxis*, Less.; *Sylvia*, Lath.; *Motacilla*, Gm.): *Climacteris*, Temm. (*Petrodroma*, Vieill.; *Meliphaga*, Temm.): *Tichodroma*, Ill. (*Petrodroma*, Vieill.; *Certhia*, Linn.): *Geobates*, Sw.: *Tatare*, Less. (*Sitta*, Less.; *Turdus*, Gm.; *Thryothorus*, Quoy et Gaim.; *Oriolus*, Forst.).

Subfamily 5. Sittinæ.

Genera:—*Sittella*, Sw. (*Neops*, Vieill.; *Sitta*, Lath.): *Sitta*, Linn.: *Dendrophila*, Sw. (*Orthorhynchus*, Horsf.; *Sitta*, Horsf.): *Dendrodromus*, Gould: *Xenops*, Hoffm. (*Neops*, Vieill.).

Subfamily 6. Orthonycinæ.

Genera:—*Orthonyx*, Temm.: *Mohoua*, Less. (*Certhia*, Quoy et Gaim.; *Muscicapa*, Gm.; *Orthonyx*, Less.).

Subfamily 7. Troglodytinæ.

Genera:—*Rhinocrypta*, G. R. Gray (*Rhinomya*, D'Orb. et Lafr.): *Menura*, Dav. (*Parkinsonius*, Beehst.; *Megapodius*, Wagl.): *Pteroptochos*, Kittl. (*Hylactes*, King; *Megalonyx*, Less.; *Leptonyx*, Sw.): *Scytulopus*, Gould (*Myiothera*, Pr. Max.; *Platyurus*, Sw.; *Motacilla*, Gm.; *Malucorhynchus*, Menetr.; *Sylvia*, Lath.; *Troglodytes*, Kittl.; *Sylviaxis*, Less.; *Leptonyx*, D'Orb et Lafr.): *Micrura*, Gould (*Micrura*, Strickl.): *Merulaxis*, Less. (*Platyurus*, Sw.; *Malacorhynchus*, Menetr.; *Merularis*, D'Orb. et Lafr.): *Thriothorus*, Vieill. (*Sylvia*, Lath.): *Campylorhynchus*, Spix (*Turdus*, Gm. et Licht.; *Cichla*, Wagl.; *Sphenura*, Licht.; *Opetiorhynchus*, Pr. Max.; *Picolaptes*, Lafr.; *Anumbius*, D'Orb. et Lafr.): *Rhamphocænus*, Vieill. (*Troglodytes*, Sw.; *Acontistes*, Sundev.; *Scolopacinus*, Bonap.): *Troglodytes*, Vieill. (*Motacillu*, Linn.; *Anorthura*, Renn.; *Regulus*, Briss.; *Luscinia*, Linn.).

Of these genera, Mr. G. R. Gray remarks that *Anthomyza* had been previously used in botany; *Plectorhyncha* and *Oxyrhynchus* in ichthyology; *Rhinomyza* in entomology; and that *Eremobius* is very like a word employed in that science; that *Dryocopus* had been previously used in *Picidæ* and *Stenorhynchus* for a crustaceous animal. *Stenorhynchus* has also been employed to designate a genus of Seals. [Vol. xxi., p. 163.]

TENURE. The general nature of tenure and its origin and history in England are explained in the article Feudal Law. A few remarks may be made here on tenure as at present existing by the law of England, for which purpose a short recapitulation is necessary.

All land was and is held of the king either mediately or immediately. All tenures were distributable under two general heads, according as the services were free or base; and consequently there was the general division of tenures into Franktenement or free-holding, and Villeinage. The act of Charles II. (12 Car. II., c. 24) abolished military tenures, which were one kind of free services, and changed them into the other species of free services, namely free and common socage. Thus one tenure in socage was established for all lands held by a free tenure, which comprehended all lands held of the king or others, and all tenures except tenures in frankalmoyne, copyhold, and the honorary services of grand-serjeanty; and it was enacted by the same act that all tenures which should be created by the king in future, should be in free and common socage. It is particularly provided in the act which abolishes military tenures, that it shall not alter or change any tenure by copy of court-roll, or any services incident thereto, nor take away the honorary services of grand-serjeanty, other than charges incident to tenure by knights' service.

Thus it appears that tenure is still a fundamental principle of the law relating to land in England.

All the land in England in the hands of any layman is held of some lord, to whom the holder or tenant owes some service. It is by doing this service that the tenant is entitled to hold the land: his duty is a service, and the right of the lord is a seignory. The word tenure comprehends the notion of this duty and of this right, and also land in respect of which the duty is due: the land is a tenement. As already observed, all land is held either mediately or immediately of the king; and ultimately all land is held of the king. The ownership of land in England is therefore never unlimited as to extent, for he who is the owner of land in fee, which is the largest estate that a man can have in land, is not absolute owner: he owes services in respect of his fee (or fief), and the seignory

of the lord always subsists. This seignory is now of less value than it was, but still it subsists. The nature of the old feud was this: the tenant had the use of the land, but the ownership remained in the lord; and this is still the case. The owner of n fee has in fact a more profitable estate than he once had; but he still owes services, fealty at least, nnd the ownership of the land is really in the lord and ultimately in the king. For all practical purposes the owner's power of enjoyment is as complete as if his land were allodial, but the circumstance of its not being allodial has several important practical consequences.

No land in England can be without an owner. If the last owner of the fee has died without heirs, nnd without disposing of his fee by will, the lord takes the land by virtue of his seignory. If land is aliened to a person who has a cnpacity to acquire but not to hold land in England, the king takes the land; this happens in the case of lands being sold to an alien. The forfeiture of lands to the king for high treason and to the lord in cases of petty treason and murder are also consequences of tenure.

The case of church lands seems something peculiar. They are held by tenure, though no temporal services are due. This tenure was originally the tenure in frankalmoigne. By the tenure in frankalmoigne the tenant was bound 'to make orisons, prayers, masses, nnd other divine services for the soul of his grantor or feoffor,' &c. (Litt., s. 135); but he did no fealty. If land was given for 'certain divine service in certain to be done,' &c. (Litt., s. 137), the lord might distrain, and in this case it seemed the lord might have fealty; this tenure by certain service was not called tenure in frankalmoigne, but tenure by divine service. Coke, in his 'Commentary on Littleton' (96, *b*) observes, 'for this divine service certain the lord hath his remedy, as it here appears by our author, in *foro seculari*; for here it appears that if the lord distrain for not doing of divine service, which is certain, he shall upon his avowry recover damages at the common law, that is, in the king's temporal court, for the not doing of it.'

The Act which abolished military tenures could not from its terms affect tenure in frankalmoigne; but for greater caution it was declared that this act should not subject tenures in frankalmoigne to nny greater or other services. Tenure in frankalmoigne therefore is now exactly what it was before the 12th of Charles II. was passed. Church lands then, which are held in frankalmoigne, still owe no services; but the lord of whom they are held must be considered the owner. And this conclusion is consistent with and part of the lnw of tenure, by which no lnnd in England is ever without an owner. Church land differs from land held by laymen in this, that the beneficial ownership can never revert to the lord, for all spiritual persons are of the nature of corporations, and when a parson dies, the corporation sole (as he is termed by an odd contradiction in terms) is not extinct, and it is the duty and right of some definite person to name a successor. It is stated by Blackstone (i. 470) that 'the law has wisely ordained that the parson, *quatenus* parson, shall never die any more than the king, by making him and his successors a corporation; by which means all the original rights of the parsonage are preserved entire to the successor: for the present incumbent nnd his predecessors who lived seven centuries ago, are in law one and the same person.' But notwithstanding this ingenious attempt to make a man, together with others not ascertained, a corporation, the difficulty really is, that when a parson dies, there is no person who has a legal ownership of the land until a successor is appointed, if Blackstone's theory is true. The comparison of the case of a parson with that of the king is unapt, for the successor to a deceased king is ascertained by the death of his predecessor; but the successor of a parson is generally ascertained by the will of some other person being exercised, and till the person entitled to appoint a parson has named one, and he has been duly instituted, the lands of the church have no legal owner, unless the lord is the owner. This seignory may be worth nothing, but it still exists. The difficulty may indeed be solved without the supposition of a seignory still existing, and in the following manner. There is succession in the case of one parson succeeding another, for which the notion of a corporation is not necessary. The notion of succession is this: the right which is the object of the succession, continues the same; the subject, that is, the person, changes. In order to constitute strict succession, the new ownership or right must begin at the moment when the former ceases, and the new ownership or right is derived from and founded on a former ownership or right. This is the case of succession to the crown. In the case of a parson, when a new one is appointed, his right by n fiction of law commences at the time when his predecessor's right ceased, though an interval has elapsed between the time of his predecessor's death and his own appointment; and this was the doctrine which the Romnns applied to the case of a heres who did not take possession of the hereditas till some time nfter the death of the testator or intestnte. This subject is discussed by Savigny, *System des Römischen Rechts*, &c., vol. iii. When then the parson dies, the freehold may be considered to be in abeyance till the appointment of his successor, one of the few instances in the English law in which it is said that n freehold estate can be in abeyance.

No seignory, in the sense above explained, can now be created except by the king. It was enacted by the statute Quia Emptores (18 Edw. I.), that all feoffments of land in fee simple must be so made that the feoffee must hold of the chief, that is, the immediate lord of the aliening tenant, by the same services by which the tenant held. Therefore all seignories exist now which existed nt the time when the statute of Quia Emptores was passed. A lord may release the services to a tenant; but it would be consistent that the king could not release the services due to him, for if that were the case land might become allodial, and on the death of a person without heirs there might be land without an owner, which is inconsistent with the fundamental principles of law relating to English land. Still it is said that the king can release to his tenant all services, and yet that the tenant holds of him: by this assumption of a still subsisting tenure the consequence above mentioned is nvoided.

Tenure of an imperfect kind may be created at present. Wherever a particular estate is created, it is held of the reversioner by an imperfect tenure: this is the common case of landlord and tenant. If no rent or other services are reserved from the tenant of the particular estate for life or years, the tenure is by fealty only, and he may be required to take the oath of fealty. But the right of the reversioner to whom services are due is solely incident to the reversion, and is created at the same time with it. The perfect tenure originated in the pure feudal system, in which the seignory of the lord was the legal ownership of the land, and the tennnt owed his services for the enjoyment of it. The only perfect tenure now existing is Socage tenure, the services of which are certain, and consist, besides fealty, of some certain annual rent. [Socage.]

The right of wardship was one of the incidents to military tenures. The lord had a right to the wardship of his infant tenant until he was twenty-one years of age; nnd this right was in many respects prejudicial to the interests of the heir. This right was abolished with the abolition of military tenures. The right of guardianship to an infant tenant in socage only continues to the age of fourteen; but the act of Charles II. (12, c. 24) gave a farther power by deed or will, executed as the statute prescribes, to appoint a guardinn to nny of his children till their full age of twenty-one, or for any less time. The guardian in socage was the next of kin to the heir, and he was chosen from that line, whether paternal or maternal, from which the lands had not descended to the heir, and consequently such guardian could never be the heir of the infant. This wardship then had no relation to tenure.

If the services due in respect of n perfect tenure are not rendered by the tenant to the lord, he may distrain, that is, take any chattels that are on the land in respect of which the services are due; and nn imperfect tenure so far resembles a perfect one, that a reversioner can distrain for the services due from the tenant of the particular estate.

A right still incident to a seignory such as a subject may have is that of escheat, which happens when the tenant in fee-simple dies without leaving any heir to the land, and without having incurred any forfeiture to the crown, as for high treason. It has been observed that the acquisition by escheat is not a purchase, because the escheated land descends as the seignory would have descended. When lands are forfeited to the king for treason, or to the lord for petty treason or murder, the tenure is extinguished; and generally, in whatever way lands come to the king or lord, the tenure is of necessity extinguished.

The nature of tenure as it exists at present will be bet-

ter understood by consulting the following articles: [Copyhold; Distress; Feudal System; Manor; Rent; Tenant.]

TEOS (Τέως), now called Búdrúm, a town of Ionia, situated on the south-side of the peninsula between the gulf of Smyrna and the gulf of Clazomenæ, very near Cape Courco, in 38° 15′ N. lat., 26° 30′ E. long. It was originally colonized by Minyæ from Orchomenus, under Athamas, and afterwards strengthened by a colony from Athens, at the time of the Ionian migration, under Nauclus the son of Codrus, Apœcus and Damasus, and by one from Bœotia led by Geres. (Pausan., vii. 3.) Teos was one of the twelve cities which formed the confederacy of the Panionium (Herod., i. 142), and was recommended by Thales from its central position as the place of congress for all the Ionian states. It was also one of the four cities of Ionia which participated in the Hellenium at Naucratis in Egypt in the time of Amasis. (Herod., ii. 178.) On the conquest of Ionia by Cyrus the Teians retired to Abdera in Thrace, where they founded a colony which eclipsed the parent state. (Herod., i. 168.) At the battle of Lade seventeen Teian ships are mentioned among the forces of the Greeks. Teos still existed as an Ionian city during the Peloponnesian war. The Teians revolted after the failure of the Sicilian expedition from the Athenians, and destroyed the wall which they had built towards the continent (Thucyd., viii. 16, 19); but Teos submitted shortly afterwards to Diomedon, the Athenian general.

Teos was the birth-place of Apellicon, the preserver of the works of Aristotle, and of Anacreon, to whom a statue was erected there (Pausan., i. 25), and who is represented on the coins of the place playing on his lyre. It appears from Livy (xxxvii. 28) that it had two ports, one in front of the city, and the other, Geræ, not quite four miles to the north-west, the entrance to which was so narrow as hardly to admit two ships at a time; it is now the site of the castle of Sigah-jik, whence a Sanják receives its name.

Chandler says of Teos, 'We found it almost as desolate as Erythræ and Clazomenæ. The walls, of which traces are extant, were, as we guessed, about 5 miles in circuit; the masonry handsome. It was with difficulty we discovered the temple of Bacchus; but a theatre in the side of the hill is more conspicuous. The vault only, on which the seats are ranged, remains, with two broken pedestals, in the area. The city port is partly dry, and sand-banks rise above the surface of the water. On the edge are vestiges of a wall, and before it are two small islets. On the left hand, or toward the continent, is a channel, which seemed artificial, the water not deep. The heap of the Temple of Bacchus, which was visible from the theatre beneath, on the right hand, lay in the middle of a corn-field, and is overrun with bushes and olive-trees. It was one of the most celebrated structures in Ionia. The remains of it have been engraved at the expense of the Society of Dilettanti, and published, with its history, in the "Ionian Antiquities" (i., ch. i.).' (*Travels in Asia Minor*, pp. 111-2; see also Choiseul Gouffier, *Voyage Pittoresque*, pl. 124.) This temple is an example of the eustylus of Vitruvius, who tells us that it was a monopterus hexastylus. It was the work of Hermogenes, the inventor of the eustylus, and is probably of the time of Alexander the Great. (Müller, *Archäologie der Kunst*, 109.) Leake (*Asia Minor*, p. 350) states the diameter of the columns to be 3 feet 8 inches at the base; he considers the whole length of the front to be about 64 feet on the upper step, with about 11 columns at the sides, as at Priene. According to Diodorus (iii. 63), the Teians believed that Bacchus was born there, and, on his account, their territory was asylus (ἄσυλος), that is, sacred or protected against violation. On the autonomous coins of Teos there are griffins, as on those of Abdera: perhaps this type is connected with the worship of Apollo. The imperial series extends from Augustus to Gallienus. (Mionnet, *Recueil des Médailles Antiques.*)

TEPHRODORNIS, Mr. Swainson's name for a genus of *Drongo Shrikes, Dicrurinæ*. [Shrikes, vol. xxi., p. 416.]

Generic Character.—Bill resembling *Prionops;* the base and the nostrils being partially covered with procumbent setaceous feathers and bristles. Wings moderate, rounded. Tail rather short, perfectly even. Tarsi and toes short; the lateral toes unequal; hinder toe longer than the tarsus. (Sw.)

Examples, *Tephrodornis superciliosus*, Sw., and *Tephrodornis Indica* (J. E. Gray). G. R. Gray (*Ind. Zool.*).

Locality.—Warm latitudes of the Old World.

Bill of Tephrodornis, Sw.

TEPHRO'SIA (from τεφρός, ash-coloured), the name of a genus of plants belonging to the papilionaceous division of the order Leguminosæ. The genus consists of shrubs or herbs, with usually unequally pinnated leaves, and lanceolate or subulate stipules distinct from the petiole. The flowers are white or purplish, arranged in racemes which are mostly axillary. The calyx is without bracts, 5-toothed, nearly equal; vexillum of corolla large, silky outside, and reflexed in a spreading manner; wings adherent to the keel; stamens separate or united in one or two parcels: legume mostly sessile, linear, compressed, many-seeded, with the valves flat; seeds compressed. This genus at present includes 84 species, but it is probable that a more accurate investigation will result in making several genera of the present one. The American and Asiatic species are in some measure distinguished by their properties. In the former a narcotic poison is more frequently secreted; in the latter a colouring-matter.

T. toxicaria, the poison Tephrosia, is a half-shrubby erect plant, with 18 to 20 pairs of oblong-lanceolate, obtuse leaflets, pubescent on the upper surface, silky beneath; legumes linear, velvety, mucronate. This plant is a native of the West Indies and of Cayenne, and is said by Tussac to have been first brought from Africa. The whole plant affords a narcotic poison, and if the leaves are taken and pounded, and then thrown into water where there are fish, they become intoxicated, and losing all power over their muscles, they float about as if dead, and may be easily caught. If placed in fresh water, or the fresh water be allowed to come in contact with them as in a stream, the fish soon recover. It is, however, generally fatal to the smaller fish.

T. Virginiana, the Virginian Tephrosia, is an erect herbaceous plant, with leaves containing from 8 to 11 pairs of oval-oblong acute leaflets, villous beneath; the calyx is also villous. It is a handsome plant with reddish flowers, and is covered with villi. It is found in woods on dry and sandy soils in North America from Canada to Florida. It is considered in America a powerful vermifuge. Several other species of Tephrosia are found in North America, and are abundant on dry and sandy soils, in Georgia, Florida, and the Carolinas.

T. emarginata is an arborescent plant, with tomentose branches, leaves with 14 pairs of linear-oblong deeply emarginated leaflets, and silky straightish legumes. It is a native of South America, and has been found about the mission-stations of the Orinoco. The root possesses the same properties as the T. toxicaria, and is also used for the purpose of poisoning fish.

T. tinctoria, the Ceylon Indigo, is a shrubby glabrous plant with five pairs of leaflets, silky and villous beneath; flowers purple or flesh-coloured, seated on axillary peduncles; straight, pendulous legumes. This plant is a native of Ceylon, where it is called *Anil*. Its tissue yields a blue colouring-matter, which has the same properties as the indigo, and is used in Ceylon for the same purposes. There are other plants used in Ceylon for dyeing, also called *Anil*.

T. piscatoria, the Fisher's Tephrosia, is a shrubby plant with five or six pairs of leaflets, which are pilose beneath, the peduncles are 2-edged, the legume straight, ascending, and rather villous. This plant is found in the East Indies, and also in the islands of the Pacific. It contains the narcotic principle of the genus, and is used in the East Indies for the same purpose as *T. toxicaria* is in the West Indies.

T. Apollinea is shrubby, and covered with a close pubescence; the leaflets are silky beneath, and in two or

three pairs; the legume is 6- or 7-seeded, and rather pubescent. It is a native of Egypt, and yields a blue colouring-matter, which is used in dyeing.

T. Senna, Buga Senna, is a glabrous shrub, with leaves having six pairs of leaflets, and the legumes and calyxes covered with pubescence. It grows on the banks of the river Cauca, near Buga, in Popayan. Its leaves have a purgative quality like senna, and are used by the natives for the same purposes as that plant is used.

In the cultivation of these plants a mixture of loam and peat should be used. They may be easily propagated by seeds, or by young cuttings planted in sand, and covered with a bell-glass. Some of the species require the heat of a stove.

TEPIC. [Mexican States.]

TEPLITZ, TOEPLITZ, or TEPLICE, a town in the circle of Leitmeritz in the kingdom of Bohemia, celebrated for its warm sulphureous springs, is situated in 50° 38′ N. lat. and 13° 50′ E. long. The name is Slavonian, and given by the Bohemians and Croatians to warm springs in general. The tradition respecting the discovery of these springs is, that a servant of a Chevalier Kolastug, a vassal of Duke Przemysl, who resided in the neighbourhood, was one day driving the swine,when several of the animals perished in the hot springs. This is said to have happened in the year 792. This discovery induced the chevalier to build a castle, and many settlers were soon attracted by the salubrious properties of the water, so that a street (in Slavonian, *Alice*) was formed, which was called Tepla Alice, 'the warm street,' and by contraction Teplice, or Teplitz.

This small town, which has not above 2500 inhabitants, is situated on a stream called the Saubach, in a beautiful plain or valley four leagues in length and one in breadth, formed by the Erzgebirge and the Mittelgebirge. The town forms an irregular quadrangle, is about half a league in circuit, and has three gates. The principal buildings are —1, the palace of Prince Clary, to whom the town belongs, with an extensive garden and park open to the public, in which there is a ball-room and a pretty theatre; 2, the church of St. John the Baptist; 3, the townhall, built in 1806; 4, the chapel of the Cross, outside of one of the gates. The town is connected by a row of handsome houses with the village of Schönau. There are several springs both in the town and in Schönau, each of which supplies several public and private baths distributed in different establishments. 'The quantity of water which the principal spring yields,' says Dr. Granville, 'is truly marvellous, being not less than a thousand large pailfuls, or one million one hundred and eighty-nine thousand six hundred and seventy cubic inches in an hour.' The temperature of these springs is said to have increased within the last forty years from 117° to 122° Fahrenheit, which is the present temperature of the chief spring. The medicinal effects of the hot springs of Teplitz are allowed by all physicians acquainted with them to be very beneficial in cases of suppressed gout, chronic rheumatism, diseases of the joints, contracted limbs, old wounds, obstinate cutaneous eruptions, paralytic affections, to which Dr. Granville adds, 'that the specific virtue of these baths lies in the power they possess of restoring a cripple, it matters little from what cause, to perfect motion and elasticity.' The waters have been used almost exclusively for bathing; of late they have been recommended and used internally. Prince Clary has spared neither pains nor expense to render the place worthy of the patronage of the kings and princes who habitually visit it, some of whom have built palaces for themselves and public hospitals for their invalid soldiers. The number of visitors every year is from 4500 to 5000. Besides the attraction of its waters, it may be added that the expense of living at Teplitz is far less than in any other watering-place in Germany, that the private baths are fitted up in a manner unquestionably superior to those of any other Spa in that country, and that there are ample sources of recreation and amusement without gaming, which is wholly prohibited.

(Jenny, *Handbuch für Reisende in dem Oesterreichischen Kaiserstaate; Die Oesterreichische National Encyclopädie; Conversations Lexicon;* Dr. Granville, *The Spas of Germany.*)

TEPTIARES. [Russian Empire.]

TEQUENDAMA. [Granada, New.]

TE'RAMO, PROVINCIA DI, called also Abruzzo Ultra I., is an administrative division of the Abruzzi in the kingdom of Naples, stretching east of the great Apennine ridge, and sloping down to the Adriatic sea. It is bounded on the east by the Adriatic, north by the Papal province of Fermo and Ascoli, west by the Neapolitan province of Aquila, and south by that of Chieti. The principal rivers are the Tronto, which marks the boundary between it and the Papal State, the Tordino, which flows by the town of Teramo, and the Vomano, whose several sources flow from the eastern slope of Monte Corno, called also the 'Gran Sasso d'Italia,' the highest group of the Apennines (9500 feet above the sea), which rises on the borders of the provinces of Teramo and Aquila, occupying great part of the area of both. The river Pescara, in its lower course, marks the boundary between the province of Teramo and that of Chieti.

The province of Teramo is divided into two administrative districts, Teramo and Penne, containing seventy-two communes: the whole population amounted in 1837 to 200,719 inhabitants. (Serristori, *Statistica d'Italia.*) The area is estimated at about 1000 square miles. Most of the population are employed in agriculture. There are some manufactories of silk, delft ware, liquorice, paper, cream of tartar, and leather; copper-ore is dug, and smelted and worked at Chiarino. The principal towns are, 1, Teramo, a bishop's see, the chief town of the province, and the residence of the intendente or king's lieutenant; it has a tribunale civile, or court of first instance, and a 'Gran Corte Criminale;' a royal college, a clerical seminary, several churches and convents, and about 8000 inhabitants. The surrounding country is productive in corn, fruit, and pulse. 2, Penne, or Città di Penne, is a town with about 6000 inhabitants. 3, Civitella del Tronto, a small fortified town on the frontier of the Papal State. 4, Atri, a small town which gives the title of duke to the antient family of Acquaviva. (Petroni, *Censimento dei Reali dominj di quà del Faro;* Neigebaur, *Gemälde Italiens.*)

TE'RAPHIM (תְּרָפִים; Sept., εἴδωλα). This is a word of somewhat uncertain etymology and signification. That the teraphim were of human form seems evident from 1 *Sam.*, xix. 13. They appear to have been superstitiously, if not idolatrously, reverenced as penates, or household gods (*Gen.*, xxxi. 19, 34, 35; I *Sam.*, xix. 13-17; 2 *Kings*, xxiii. 24). In some shape or other they were used as domestic oracles (comp. *Zech.*, x. 2; *Judg.*, xvii. 5; xviii. 5, 6, 14-20; *Hos.*, iii. 4). This is confirmed by 1 *Sam.*, xv. 23, where teraphim are mentioned in connection with the arts of divination. With this the alleged Syriac etymology of the word coincides; for, according to Bar Bahlul, תְּרָף means in that language, *an inquirer, one who asks.*

TERBURGH, GERARD, a very eminent painter of scenes of domestic life of the lugher classes of society, was born at Zwoll, near Overyssel, in the year 1608, and was instructed in the rudiments of his art by his father, who is not much known as a painter, but appears to have passed some years at Rome. Some think that he perfected himself under another master at Haarlem; however this may be, he had acquired considerable reputation in the Netherlands as a painter of portraits of a small size, before he resolved to travel for his improvement. He first visited Italy; but whatever advantage he may have derived from the works of the great Italian masters, he never changed his style, and proceeding from Italy to France, practised with great success at Paris. From France he returned to Holland, where he was highly esteemed and fully employed. He visited Münster during the sitting of the celebrated congress at which the treaty that terminated the Thirty Years' War was concluded. Here he painted his most celebrated picture, containing the portraits of the sixty-nine plenipotentiaries assembled on that important occasion. Count Pigoranda, the Spanish ambassador at Münster, induced him to visit Spain, where he painted the portraits of king Philip IV. and all the royal family, and of many of the most distinguished nobility. His performances gave such satisfaction to the Spanish king, that he conferred on him the honour of knighthood, and presented him with a gold chain and medal, a sword, and silver spurs. After finally returning to his own country he married, and was made burgomaster of the town of Deventer, where he lived in affluence, and died in 1681, at the age of seventy-three years.

The subjects which Terburgh generally painted were

portraits, conversations, persons engaged at different games, performers on musical instruments, ladies at their toilets. He finished his pictures highly, with a light and delicate touch, and is remarkable for introducing white satin in the dress of some figure in all his compositions: he always took care to throw the principal light upon it, and seems never to have painted a picture without satin drapery. Dr. Waagen says of him, 'Terburgh is the real founder of the art of painting conversation pieces, and at the same time the most eminent master in this style. In delicacy of execution he is inferior to none, and in a certain tender fusing of the colours he excels all others; but none can be compared with him in the enchanting harmony and silvery tone, and the observance of the aërial perspective. His figures, which are well drawn, have an uncommon ease of refinement, and are frequently very graceful.' Many of his capital works are in England, in the collections of Sir Robert Peel, the duke of Sutherland, Lord Ashburton, Mr. Hope, the marquess of Bute, and Her Majesty. (Pilkington; Fuseli; Dr. Waagen.)

TERCEIRA is considered the principal island of the Azores or Western Islands, though it is neither the largest nor the most fertile. It is situated nearly in the centre of the group, and it is the seat of government. It extends between 38° 36′ and 38° 50′ N. lat., and between 26° 58′ and 27° 22′ W. long., and is about 20 miles long from east to west, with an average width of about 13 miles. This gives an area of 260 square miles, or about 60 square miles more than the smallest of the English counties, Rutlandshire.

Terceira, and all the other Azores, with the exception of Santa Maria, has probably been produced by volcanic action, but its surface does not exhibit that extreme irregularity which occurs in the other islands, and in general in countries which owe their existence to that agency. The coasts indeed are rocky and precipitous, but the higher parts of the island are chiefly composed of beautiful and fertile plains, and entirely destitute of the numerous cones, craters, and peaks which distinguish the island of St. Michael. There is however, about 6 or 7 miles north-west of the town of Angra, a wide depression, from the crevices of which sulphuric vapours issue in abundance, and which is surrounded by hills composed of pumice-stone. It is called Furnas de Euxofre. It is stated that these crevices were formed by the earthquake of 1614, which was the last experienced in the island, up to 1841, when the town of Praya was completely destroyed by an earthquake, and the whole island suffered much. The interior of the island does not contain many steep or inaccessible rocks, which is mainly to be attributed to the earth-slips which have been very frequent, and still happen from time to time. The most elevated part of the island is in the middle, and extends from east to west, where it terminates with Punta Seretta. Near this cape, and north-east of it, the ground seems to attain its greatest elevation, which however probably does not exceed 3000 feet above the sea-level. The elevated rocky coast along the western and northern shores cannot be approached without great danger by large vessels, and the whole island has only three harbours, Praya on the east, Angra on the south, and Biscoitos on the north-west, but the anchorage is bad, and with certain winds vessels are obliged to seek the open sea. The soil is composed of volcanic ashes, pumice-stone, slags, decomposed lava, a quantity of ferruginous matter, a small portion of clay or sand, and a little limestone. But a large quantity of vegetable matter is mixed with these materials, which imparts to the soil a considerable degree of fertility. Grain is only cultivated on the more level and low tracts along the sea-coast. The interior is overgrown with trees.

No meteorological observations have been published, but the climate is known to be very moderate, as it is stated that the average range of the thermometer is only from 50° to 75°, and rarely exceeds these two extremes. But the weather is nevertheless subject to great changes, and is only settled between the summer solstice and the autumnal equinox. Showers of rain are frequent throughout the year, and in winter so violent as to cause constant changes in the face of the country, washing away enormous masses of pumice-stone from the mountains, throwing down projecting portions of the rocks composed of soft volcanic materials, and leaving the surface of the rocks and heights in many places quite destitute of soil. The number of fine days is estimated at about 200, and the wet ones at sixty. The sea which surrounds the Azores is remarkable for the incessant gusts and gales to which it is subject, on which account it is rather dreaded by seamen. This phenomenon is probably connected with the Gulf-stream, which reaches the most western islands (Flores and Corvo), and frequently extends over the whole group. All navigators have observed the frequency of these gusts and sudden squalls, especially along the northern edge of the Gulf-stream. The prevailing winds during the winter range between north-west and south-west; the south-west wind generally blows in strong gales, and is attended by heavy rains. During the summer the most frequent are northerly, north-easterly, and easterly winds; but at all seasons the changes of the winds are frequent and sudden, and render the navigation between the islands very tedious.

The soil being more suitable to agriculture and pasturage than to the cultivation of fruit, grain and cattle are the staple articles. The principal objects of cultivation are wheat, Indian corn, flax, French and broad beans, and a little barley. The yearly produce of the grain is stated to be 720,000 bushels, and some is exported to Lisbon, Oporto, and Madeira. The most common vegetables are yams, potatoes, sweet potatoes, onions, and capsicums. All the fruit-trees of southern Europe succeed, but their cultivation has been neglected until lately, when the inhabitants have begun to apply themselves to that of the orange-tree, and the oranges of Terceira are now hardly inferior to those of St. Michael, and are largely exported to England and Hamburg. The vineyards are extensive, and their annual produce exceeds 4000 pipes, but the wine is converted into brandy, and the wine consumed in the island is imported from Fayal. The apples, pears, figs, chestnuts, and wallnuts are tolerably good. On the declivities there are some pine-woods and beech, but the higher parts are covered with underwood and impenetrable bushes of briars, among which are many evergreens, such as myrtle, juniper, and box, with stunted cedars. Quantities of orchilla are collected from the rocks. Cattle are numerous, and of good size in the cultivated parts, and those parts which are not cultivated serve as pasture-grounds for sheep and goats. Goats are rather numerous. Only a few small horses are reared; the oxen and asses, which are numerous are used as beasts of burden. Hogs are very numerous, and are fed on Indian corn and chestnuts. There are no wild animals, except rabbits, and no poisonous reptiles. Fowls and turkeys abound. There are thousands of blackbirds, woodcocks, and partridges, but no pheasants nor peacocks. Fish is said to be abundant. Sometimes whales are seen near the island.

In 1820 the population amounted to 40,717, and in 1832 it was estimated at 50,000 individuals, which gives more than 192 persons to each square mile, rather a large proportion when it is considered that much more than half the island is not cultivated and does not produce food for man. Lincolnshire has only 130 to each square mile, according to the census of 1841. This population is settled in three towns and fifteen villages. Angra is the capital. [ANGRA.] Praya, which has about 3000 inhabitants, is situated in the centre of a beautiful sandy, deep, indented bay, well defended by nature and art, and has some commerce with Portugal and Madeira: it exports grain and live-stock.

Very good linen and coarse woollen-cloth is made on the island for home consumption. Coarse earthenware is also manufactured to a considerable extent, the clay for which is imported from Santa Maria. The exports consist of grain and live-stock, which go to Portugal and Madeira, and of brandy, oranges, and orchilla, which go to foreign countries, chiefly England and Hamburg. The imports are principally coarse cotton fabrics, some woollen-cloth, hardware and cutlery, and cod, most of which articles are brought from England.

Terceira was discovered in 1445 by some Portuguese navigators who were returning to Europe from Cape Verde, and it then received its present appellation, being the third of the Azores in the order of discovery. It was then uninhabited, but it was immediately settled by several families from Portugal. In 1580, when Philip II. took possession of Portugal, the inhabitants declared against him, and repulsed his fleet from their shores; but in 1583 they were obliged to submit. In 1828, when Don Miguel

had abolished the constitutional government of Portugal, and proclaimed himself absolute king, Terceira declared for Donna Maria; and, in 1829, a large fleet and army sent by Don Miguel for the conquest of the island were repulsed with great loss from the town of Praya. In 1831 the other islands of the group were recovered for Donna Maria by a small number of troops sent there from Terceira.

(Ashe's *History of the Azores* or *Western Islands*; Von Buch's *Physikalische Beschreibung der Canarischen Inseln*; Fowler's *Journal of a Tour in the State of New York, and Return to England by the Western Islands*; Boid's *Description of the Azores or Western Islands*; and Capt. Bartholomew, in *London Geographical Journal*, vol. iv.)

TEREBELLA. [TUBICOLIDÆ.] (N.B. This comes too near to *Terebellum*.)

TEREBELLA'RIA, a genus of Polypiaria, included by Blainville in the family of Milleporæa.

TEREBELLUM, Lamarck's name for a genus of testaceous mollusks, placed by Cuvier among his Pectinibranchiate Gastropods, between *Ovula* and *Voluta*; by De Blainville among his *Angyostomata*, between *Conus* and *Oliva*; and by Rang between *Mitra* and *Ancillaria*.

The fossil *Terebellum convolutum* is the type of Montfort's genus *Seraphs*.

Generic Character.—Animal?

Shell delicate, polished, subcylindrical, rolled upon itself; the apex pointed; the aperture longitudinal and triangular, very narrow behind and notched before; edge of the right lip simple and trenchant; columellar border smooth, truncated, and slightly prolonged forwards.

There appears to be but one recent species known, *Terebellum subulatum*.

De Blainville divides the genus into two sections:—

A. Species whose spire is visible, and whose aperture is shorter than the shell. (*Terebellum*.)

B. Species whose spire is nearly entirely hid by the rolling up of the whorls of the spire, and whose aperture is nearly as long as the shell. (*Seraphs*, fossil.)

Example, *Terebellum subulatum*.

Description.—Shell subulate-cylindrical, rather thin, smooth, and polished; the spire distinct; the outer lip attached to the columella.

There are at least four varieties:—

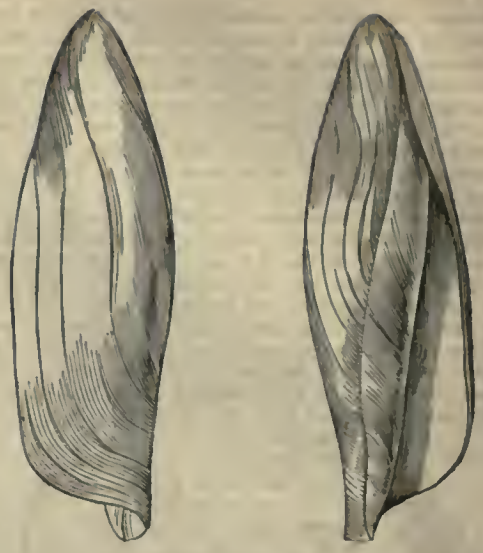
A. Clouded with chestnut, quadrifasciate, or with the colour in patches.
B. Ornamented with flexuous subspiral or transversely oblique chestnut lines.
C. Thickly dotted with rich chestnut.
D. Entirely white.

Locality.—The East Indies.

Terebellum subulatum.

FOSSIL TEREBELLA.

The fossil species appear to belong to the Tertiary formation, Eocene period of Lyell (Grignon, &c.). M. Deshayes, in his Tables, notices but two, *Terebella convolutum* and *fusiforme*, the same that are recorded by Lamarck.



Terebellum convolutum. (Genus *Seraphs* of Montfort.)

TEREBINTA'CEÆ, a natural order of dicotyledonous plants. They are trees or shrubs, abounding in a resinous, gummy, caustic, poisonous, and sometimes milky juice. The leaves are alternate and simple, ternate, or pinnate. The flowers are terminal or axillary, mostly unisexual. The calyx is small. The petals and stamens are equal in number to the divisions of the calyx; sometimes the stamens are twice the number; the disk is fleshy; ovary simple; fruit indehiscent, with a single exalbuminous seed.

This order was constituted by Jussieu, and is adopted by De Candolle, Arnott, Don, and other writers on systematic botany. Brown has however constructed five orders from this, viz., Anacardiaceæ, Burseraceæ, Connaraceæ, Spondiaceæ, and Amyridaceæ. These orders have been recognised by Kunth, Lindley, and others; and their characters and properties are given in this work under their respective names. [ANACARDIACEÆ; BURSERACEÆ; CONNARACEÆ; SPONDIACEÆ; AMYRIDEÆ.]

TE'REBRA. [ENTOMOSTOMATA, vol. ix., p. 453.]

TEREBRA'LIA, Mr. Swainson's name for a genus of testaceous Gastropods, arranged by him under the *Cerithinæ*, the fifth subfamily of his *Strombidæ*, and thus characterized:—

Outer lip much dilated, generally uniting at its base to the inner lip, leaving a round perforation at the base of the pillar; channel truncate, opercule round. (*Malacology*.)

Mr. Swainson places the genus between *Pirena* [MELANOPSIS] and *Rhinoclavis*, Sw.; and, among other species, refers to *Terebralia Telescopium*, *Cerithium Telescopium* of authors. [ENTOMOSTOMATA, vol. ix., p. 451.]

Whatever may be thought of this genus, the name, from its coming so near to *Terebra*, may produce confusion.

The reasons for not admitting *Pirena* as a genus will be found in the article MELANOPSIS.

TEREBRA'TULA. [BRACHIOPODA, vol. v., p. 311.]

TEREDI'NA, a testaceous mollusk of the family *Tubicolæ* of Lamarck, and belonging to the *Adesmacea* of De Blainville.

Generic Character.—Valves equal, but inequilateral; umbones prominent; when closed, orb-like with a wide angular opening in front and a subcircular aperture at the back. Tube testaceous, subcylindrical, with a terminal posterior extremity, without any septum, uniting to the posterior part of the two valves.

This genus is fossil only. Lamarck places it between *Septaria* [TEREDO] and *Teredo*; Cuvier between FISTULANA and CLAVAGELLA.

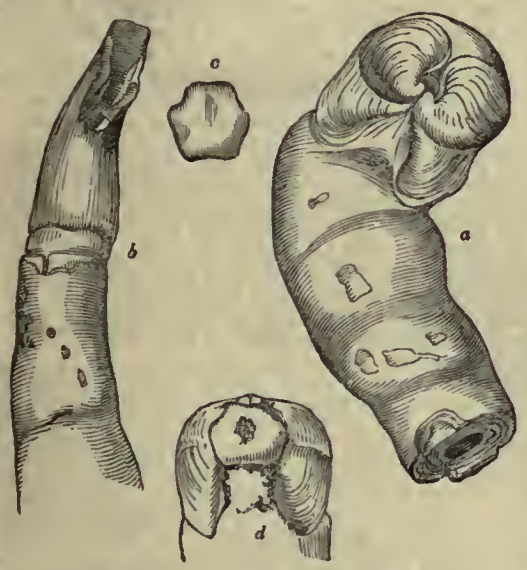
Mr. Swainson arranges it in his family *Pholidæ*, and makes it a subgenus of *Teredo*.

Mr. J. E. Gray places *Teredina* among the *Pholadæ*, between *Jouannetia* and *Teredo*.

M. Deshayes, in the last edition of Lamarck, observes that this curious genus was not well known to that zoologist. The *Teredina*, M. Deshayes remarks, is a true

globular Pholas fixed at the end of a tube, and has in fact the exterior characters of the *Pholades*. It carries an escutcheon on the umbones, and within it is provided with those appendages which so readily distinguish the *Teredines* and the *Pholades* from other genera. The shell is always external, and soldered by the posterior extremity of its valves to the anterior part of the tube, which is very thick and terminated by a blackish part of a horny appearance, whose internal surface is sometimes divided into eight regular earinations.

M. Deshayes, in his Tables, gives two species, *Teredina personata* and a new species, both from the tertiary beds (Eocene of Lyell). In the last edition of Lamarck no notice is taken of the new species, and to the second species, *Teredina bacillum*, recorded by Lamarek, is appended a note stating that this last does not belong to the genus *Teredina;* and that, according to the description and figure of Broechi, it can only be a *Clavagella* or a *Fistulana;* but that it is not *Clavagella tibialis*, as M. de Blainville believed.



Teredina personata. (Coortagnon, &c.)

a, tube with valves; *b*, the other termination of the tube; *c*, accessary valve; *d*, valves with accessary valve in its place. (G. B. Sowerby.)

TERE'DO, the name given by Linnæus to a genus of testaceous mollusks, highly interesting on account of the ravages which one of the species commits upon submerged wood.

Linnæus, in the twelfth edition of the 'Systema Naturæ,' placed the genus among his *Vermes testacea*, between *Serpula* and *Sabella:* nor is this certainly inapt position to be wondered at when we consider the very infant state of malacology in his day.

Cuvier, in his last edition of the 'Règne Animal,' makes *Teredo* one of the genera of his *Enfermés*, the fifth family of his *Acephalous Testaceans*, arranging the genus between *Pholas* and *Fistulana*.

M. de Blainville arranges the genus in the tenth family (*Adesmacea*) of his *Pyloridians*, between *Teredina* and *Fistulana*, immediately after which comes *Septaria*.

Lamarck had placed the genus among his *Tubicolées*, and M. Rang adopts that arrangement, giving it a position however between *Jouannetia* and *Fistulana*, next to which, and immediately before Teredina, *Septaria* appears.

Lamarck ended with this genus his *Tubicolées*, which are immediately followed by the *Pholadaires*. *Teredo* is immediately preceded by *Teredina*, and this again by *Septaria*. In speaking of the last-named genus, M. Deshayes, in the last edition of Lamarck, observes that although the animal and the shell of *Septaria* are not known to him, the great portions of its testaceous tube or sheath, which he had seen, convinced him that the animal is analogous to that of the *Fistulanæ*, which differ from it principally in size only; and because its two anterior siphons are very long, and form for themselves each a particular testaceous sheath. The animal ought therefore to have posteriorily, he remarks, a bivalve shell, which had escaped those who have collected the great tube, or the portions of it which we see in cabinets. M. Deshayes goes on to state that he has only seen a few septa, unequally distant and entirely incomplete. Some *Fistulanæ*, he adds, have also vaulted septa in the posterior part of their sheath; but the diminished or anterior part of this offers only particular tubes projecting outwards (1835).

Again, when Lamarek concludes *his* observations by saying that, for the rest, the *Septaria* is hardly anything but an exaggerated *Fistulana*, and scarcely deserves to be distinguished as a genus, M. Deshayes declares that if we substitute for the word *Fistulana* that of *Teredo*, these remarks would be perfectly just. This genus, he adds (Lamarck's *Septaria*), which had been believed to be peculiar to the seas of India, has been found some years since in the Mediterranean; and he refers to the paper published on that animal in the 'Annales des Sciences et de l'Industrie du Midi de la France,' Marseille, 1832, by M. Mathéron, in which that naturalist proves the animal of *Septaria* to be similar to that of *Teredo;* and this resemblance, says M. Deshayes, in conclusion, confirms his own opinion of the necessity of uniting the *Septariæ* and the *Teredines*.

Mr. Swainson (*Malacology*, 1840) places *Teredo* with the subgenera *Teredo* and *Teredina*, at the end of the '*Pholidæ*.'

Mr. J. E. Gray arranges *Teredo* between *Teredina* and *Bankia*, under his *Pholadæ*, the first family of his second order (*Cladopoda*) of *Conchifera*. *Septaria* is introduced, with a query, into his second family, *Gastrochænidæ*.

Organization.

It is now 36 years since Sir Everard (then Mr.) Home laid before the Royal Society, with the assistance of Mr. Clift in making the drawings, and the aid of Sir Benjamin (then Mr.) Brodie, his *Observations on the Shell of the Sea-Worm found on the Coast of Sumatra, proving it to belong to a Species of Teredo, with an account of the Anatomy of the Teredo Navalis*. Sir Everard remarks that the internal structure and economy of *Teredines* were so little known, and so much of what was said of them by Sellius was so vague, that it became necessary to acquire an accurate knowledge of the common *Teredo navalis*, before any adequate idea could be formed of the new species, which he names *Teredo gigantea*.

On examining the shell of *Teredo navalis* while in the wood, Sir Everard found its external orifice very small, just large enough, in fact, to give a passage to the two small tubes. The greatest thickness observed was $\frac{1}{4}$ of an inch. The canal in the wood at its termination, and for an inch in length, was not lined with shell, but smeared over with a dirty green-coloured mucus, which was also spread upon the last-formed portion of shell. According to Mr. Hatchett's analysis, the shell of *Teredo navalis* was perfectly similar to that of *Teredo gigantea*, being devoid of phosphate of lime, and composed of 97 parts of carbonate of lime and 3 of animal matter.

While the animal was in the shell alive and undisturbed, what is termed the head was in contact with the end of the canal in the wood; but, on laying the head bare, it was drawn in for an inch into the shell. The body of the animal filled the area of the shell completely, but appeared much smaller when taken out, in consequence of the sea-water which it contained having escaped. The largest of the worms examined which were of different lengths measured 8 inches in length. Many of them were alive 24 hours after being removed from their shell, and in these the heart was seen to palpitate. The blood in the vessels going to the head was red, as also the parts near the liver; but this colour disappeared soon after death.

The head of the worm was enclosed between the two concave boring shells, so that what Sir Everard calls the face was the only part exposed. These shells were united together on what is termed the back part of the head by a very strong digastric muscle, having a middle tendon from which the fibres go off in a somewhat radiated direction, partly for insertion into the concave surface of each shell, and partly into a long semicircular process projecting from the posterior part of each shell. The two inclose the œsophagus and other parts surrounding it. The double muscle was inclosed in a smooth shining fascia. When first exposed it was of a bright red.

On the opposite side of the head the shells were united by a ligament from which they were readily separated; at this part were two small tooth-like processes, one from the narrow edge of each shell, where they were joined together.

From the middle of the exposed part of the head projected a kind of proboscis; which in the living animal had a vermicular motion: its extremity was covered by a cuticle not unlike the cornea of the eye. On removing this, the cavity immediately beneath it was found to contain a hard brown-coloured gelatinous substance, like a Florence flask, with the large end uppermost in form. Sir Everard remarks that as this proboscis has no orifice, there is reason to believe that it adheres to the wood, acting as a centre-bit, while the animal is at work with the shell, and thus the canal in the wood is perfectly cylindrical. The mouth was nearly concealed by the projection of the proboscis, but, when exposed, presented a very distinct round orifice between the proboscis and the large digastric muscle.

'The body of the worm,' proceeds Sir Everard, 'is inclosed in one general covering, extending from the base of the boring shell, with which it is firmly connected to the root of the two small tubes, which appear out of the wood. It terminates in a small double fold forming a cup, on the inside of which are fixed the long small stems of two opercula, which become broad and flat towards their other extremity. These, when brought together, shut up the shell, and inclose the two contracted tubes within it: not one operculum corresponding to each tube, but in a transverse direction. In the *Teredo gigantea*, the opercula are similarly situated, each shutting up one-half of the bifurcation. At the base of this cup the general covering is thick and ligamentous, for about one-fourth of an inch in length, where the stems of the opercula are connected with it; and at one spot of this thickened part there is an adhesion to the cylindrical shell, which is the only part of the animal connected with it. There is a depression in the shell pointing out this spot. The double fold of the outer covering, that forms the cup, contains the sphincter muscle, which closes the orifice by bringing the opercula together. The general covering is composed of two membranes, the outer the strongest, and made up of circular fibres, the inner much finer, having no fibrous structure. On the back of the animal, this covering is firmly connected to the parts underneath, and is there strongest. On the belly it forms a cavity, and is thinner. It is everywhere sufficiently transparent to show the different viscera through it.'

Sir Everard Home began his dissection by dividing this covering and exposing its cavity, into which there are two natural openings: one, that of the largest of the above-described tubes, by which it receives the water from the sea; the other, a transverse slit under the union of the boring shells, one-quarter of an inch long, opening into the space before the mouth. The author states that the smaller tube has no communication with this cavity, and that there is none between this cavity and that of the belly, the viscera having a proper covering of their own: the breathing organs however, which are attached on the posterior surface of this cavity, are described as having their fringed edge loose and exposed to the influence of the salt water; so that the larger tube is constantly applying salt water to them, and conveying it to the animal's mouth through the aperture for that purpose.

Digestive System.—The head and abdominal viscera were found to occupy about one-third of the animal's length, the breathing organs another third, and the space between their termination and the ends of the small tubes the remaining third. The œsophagus was very short, lying on the left side of the neck. On the right were two large approximated glands connected with its coat. The œsophagus gradually swelling out became stomach, which externally appeared as a large bag, extending the whole length of the abdomen; the intestine commenced close to the termination of the œsophagus; but when the stomach was laid open, a septum appeared dividing it into two distinct bags, except at the lower end, where they communicate. It may therefore be said, observes Sir Everard, to be doubled on itself. In those worms which were examined alive, the stomachs were quite empty; but in some preserved specimens the contents were a yellow-coloured pulp, of which we shall have to say more presently: the quantity in a specimen from the British Museum was about 10 grains.

The intestine was very small, and became dilated into a cavity, containing a hard, white, globular body, of the size of a large pin's head, and then made a turn upon itself. Here the liver is attached to the stomach, to which it firmly adheres. The gut passed forwards till it reached the central line of the stomach, opposite the septum, and continued its course along that viscus, passing round its lower end and up again on the opposite side. It was then continued on one side of the œsophagus nearly as high as the mouth, where it was reflected over the middle tendon of the digastric muscle of the boring shells, and ran along the back of the animal, till it terminated in the small tube through which its contents are emptied.

Circulating and Respiratory System.—The heart was found in the middle between the mouth and the lower end of the stomach, and was situated on the back of the animal. There were two auricles, composed of a thin dark-coloured membrane, which opened by contracted valvular orifices into two white strong tubes, which united to form the ventricle. This ventricle, Sir Everard observes, may be said to be continued into an artery, which supplies the viscera, and ascends to the muscles of the two boring shells. The heart was very loosely connected to the surrounding parts; its action was distinctly seen through the external covering, and was observed, in some instances, after it had been laid bare. The first contraction was in the two auricles, which shortened themselves in that action. A swelling of the ventricle, followed by a contraction, is thus produced. Sir Everard found that the artery from the ventricle could be traced up to the head, and the vessels from the auricles were seen very distinctly as far as the breathing organs. The auricles were lined with a black pigment, so that their contents could not be seen through them; and the coats of the ventricle were too thick for transparency: but the muscle of the boring-shells was of a red colour, as well as the liver, and most of the surrounding parts between the heart and the head.

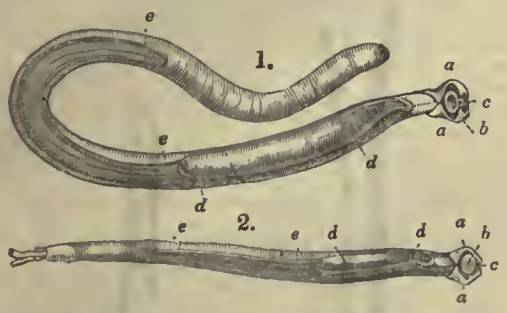
Sir Everard observes, that this structure of the heart admits only of a single circulation, as in other animals which breathe through the medium of water, but that the mode of its being performed is different from that in fishes: in the *Teredines*, he remarks, the blood passes directly from the heart to the different parts of the body, and returns through the vessels of the breathing organs to the heart, while in fishes it goes first to the breathing organs, and then to the different parts of the body. This peculiar circulation, he adds, becomes a link in the gradation of the modes of exposing the blood to the air in different animals: it appears to be less perfect than in fishes, since the exposure to the air is carried on more slowly, but is more perfect than in caterpillars.

Brain and Nervous System.—Sir Everard doubts not the existence of the brain and nerves in animals so perfect in their organs as the *Teredines*, but he failed to detect them during his investigation.

Generative System.—Sir Everard Home describes the testicles as two long glandular substances, one on each side of the stomach, of a whitish colour and granulated structure. From each of them a duct passed to the ovaria, which lay between the two breathing organs. The ducts ran upon their outer edge, and terminated near the base of the small tube. In this way, he remarks, the eggs are impregnated before they pass out at that orifice. In the worms from Sheerness, examined in February, the testicles were small, and no appearance of ovaria could be seen; but in specimens from the Hunterian Museum the testicles were much fuller, and the ovaria formed two distinct longitudinal ridges: these, when examined under the microscope, were seen to contain innumerable small eggs. When the ovaria are empty, Sir Everard states that there is nothing to be found between the two breathing organs but the small seminal vessels. He then adverts to the statement of Sellius, who says that the *Teredo navalis* has its ovaria full of eggs in the spring and summer; that they are met with as late as December; but that those individuals which he examined in February had their ovaria flaccid and empty.

With regard to *Teredo gigantea*, the same author observes that, when arrived at its full growth, it closes up the end of its shell, and so does *Teredo navalis*. Sellius believed that the animal by this act formed its own tomb,

since it could no longer destroy the wood in which it was contained. Sir Everard however remarks that in *Teredo gigantea* death is not a consequence of seclusion from the substance in which it is imbedded. In some of Mr. Griffiths's specimens the shell was just covered in, and the part close to the termination extremely thin, whilst in others it was increased twenty-fold in thickness. In others again the shell had not only become thick, but the animal had receded from its first inclosure, and had formed a second three inches up the tube, and had made the sides thicker and thicker, so as to diminish the canal in proportion to the diminution of its own size.



Animal of Teredo navalis out of the shell.

1. the opercula are wanting, and the tubes retracted. 2. the opercula in their situation, and the tubes protruded. *a, a*, the boring-shells; *b*. the proboscis; *c*, the mouth; *d, d*, the contents of the abdomen seen through the transparent external covering; *e, e*, breathing organs seen in the same way. (*Phil. Trans.*)

Sir Everard considers these facts as proving that *Teredo gigantea*, when arrived at its full growth, or whenever it is prevented from increasing in length, closes up the end of its shell, and lives a long time afterwards, furnished with food from the sea-water. *Teredo navalis*, he observes, closes up its shell in the same manner: it must therefore, after that period, be supplied with food entirely through the medium of sea-water. The *Teredines*, he adds, turn round in the shell, to which they are not attached, and with which their covering only has a slight connection at one particular spot, to prevent the external tubes from being disturbed. This motion, Sir Everard observes, is for the purpose of boring.

Generic Character.—Animal very much elongated, vermiform, with a very delicate mantle, open in front and at its lower part for the passage of a mammiliform foot; tubes separated, very short, especially that for the dejections; mouth small; labial appendages short; anus situated at the extremity of a small tube floating in the cavity of the mantle; branchiæ riband-like, united on the same line throughout their length, and a little prolonged in the siphon; a muscular ring at the point of junction of the mantle and the tubes, in which is implanted a pair of pediculated corneo-calcareous appendages or palmules, playing laterally one against the other.

Shell rather thick, very short, annular, equally open before and behind; equivalve, inequilateral, angular, with triangular valves, trenchant in front, and only touching each other by the two opposite edges; no hinge; an elongated, nearly straight, subfiliform, spoon-shaped process; a single slightly-marked muscular impression.

Tube cylindrical, straight or flexuous, closed with age at the buccal extremity, so as to envelope the animal and its shell, always open at the other, and lining the cavity into which the animal has introduced itself.

Such is M. Rang's definition of *Teredo*, excluding *Teredo gigantea* (*Septaria*), of which he gives the following definition, observing that it closely approximates to the *Teredines* and *Fistulanæ*:—

Animal unknown. (But see the paper of M. Mathéron above referred to.)

Shell unknown. (But see the descriptions of Mr. Griffiths and Sir Everard Home here noticed.)

Tube calcareous, thick, solid, in the shape of a very elongated cone, and irregularly flexuous, furnished internally with small, incomplete, annuliform septa; terminated at one of its extremities by a convexity, and at the other by two slender and separated tubes.

The number of species of *Teredo* (exclusive of *Septaria*) recorded by Lamarck in the 'Animaux sans Vertèbres' (1818) were two, *Teredo navalis* and *Teredo palmulatus*: of the latter Lamarck, who had seen neither its tube nor its shell, says that it probably only differs from *Teredo navalis* in its greater size, its longer palmules having been more easily observed.

M. Deshayes, in his Tables, makes the number five living and five fossil (tertiary), exclusive of *Septaria*; and, in the last edition of Lamarck, adds to the two species above noticed *Teredo corniformis* (*Fistulana corniformis*, Lam.), *Teredo gregatus* (*Fistulana gregata*. Lam.), and *Teredo arenarius* (*Septaria arenaria*, Lam.).

N.B. Lamarck had stated that the *Ropan* of Adanson (*Sénégal*, pl. 19, f. 2) belonged to the *Teredines*, remarking however that he (Lamarck) knew it not. But M. Deshayes points out that M. Rang, on his return from a voyage to Senegal, where he had an opportunity of observing the *Ropan*, found that this curious shell belonged neither to the *Teredines*, as Lamarck believed, nor to the *Pholades*, as Bosc says, and still less to the *Gastrochænæ*, as M. de Blainville supposes; but that it is a *Modiola* already known, *Modiola caudigera*.

Teredo Navalis.—This is sufficiently described above, and we therefore proceed to the consideration of its

Food, Habits, &c.—Some of the *Teredines* examined by Sir Everard Home were sent from Sheerness in the wood alive, and they lived in salt-water for three days after being brought to town. Sir Everard observed that when the surface of the wood was examined in a good light, while only an inch in depth in the water, the animal threw out sometimes one, at others two small tubes. When one only was protruded, the other almost immediately followed it. One of them was about three-quarters of an inch long; the other only half that size. When the largest was exposed to its full extent, there was a fringe on the inside of its external orifice of about twenty small tentacula, scarcely visible to the naked eye: these were never seen except in that state; for when the tube was retracted, the end was first drawn in, and so on, until the whole was completely inverted: and therefore in a half-protruded state it appeared to have a blunt termination with a rounded edge. The smaller tube was not inverted when drawn in. 'These tubes,' says Sir Everard Home, in continuation, 'while playing about in the water appeared at different times to vary in their directions, but usually remained at the greatest convenient distance from each other. The largest was always the most erect, and its orifice the most dilated; the smaller one was sometimes bent on itself with its point touching the wood. In one instance, where a small insect came across the larger one, the point of the smaller turned round and pushed it off, and then went back to its original situation. In several instances the smaller one appeared to be the most sensible; since by touching the larger one gently it did not retract; but on touching the smaller one they both were instantly drawn in. Indeed whenever they were retracted they always were drawn in together. When the worm was confined within the shell the orifice was not to be distinguished in the irregular surface of the wood, which was covered with small fuci. The worm appears commonly to bore in the direction of the grain of the wood, but occasionally it bores across the grain to avoid the track of any of the others; and in some instances there was only a semitransparent membrane as a partition between two of them.'

Sir Everard observes that as the *Teredo gigantea* bores in mud, on which it cannot be supposed to subsist, or even to receive any part of its nutriment from it, it becomes a question whether the *Teredo navalis*, an animal of much smaller size, derives support from the wood which it destroys, or is supplied wholly from the sea. The last opinion seems the most probable to Sir Everard, because the animal, having red blood and very perfect organs, necessarily requires a great deal of nourishment for the purposes of growth, and to supply the waste constantly going on; but if, he observes, the aggregate of shell and animal substance is taken, it will be found equal in bulk, and greater in specific gravity than the wood displaced in making the hole: hence, he remarks, it is obvious that the quantity of wood which the animal has taken into its body is wholly insufficient for its formation and subsistence. When once it is established that the *Teredo* can be supported independently of the wood which is eaten, and can afterwards subsist when the communication between it and the wood is cut off, a doubt, he adds, is created about the wood forming any part of its aliment, and it becomes pro-

bable that the *Teredo navalis*, like the *Teredo gigantea*, forms its habitation in a substance from which it receives no part of its sustenance; and that the sawdust conveyed through the intestines is not digested, particularly as that examined by Mr. Hatchett had not undergone the slightest change.

Mr. Hatchett found the ten grains of pulp from the specimen above referred to to be an impalpable vegetable sawdust. When burnt the smoke had precisely the odour of wood; it formed a charcoal easily consumed, and was converted into white ashes, in every respect like vegetable charcoal. Solution of potash did not act upon it, as it would have done if it had been an animal substance.

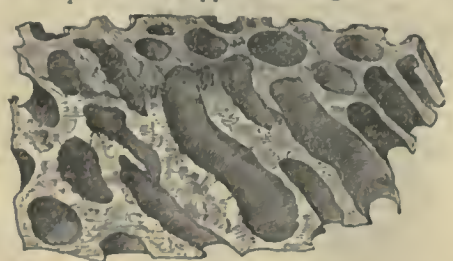
Sir Everard Home suggests that the straight course of the intestine in the *Teredines* makes it probable that the sawdust retards the progress of the food, so as to render convolution unnecessary.

Teredo Navalis has been found at depths ranging from the surface to ten fathoms.

Shell and tube of Teredo navalis.

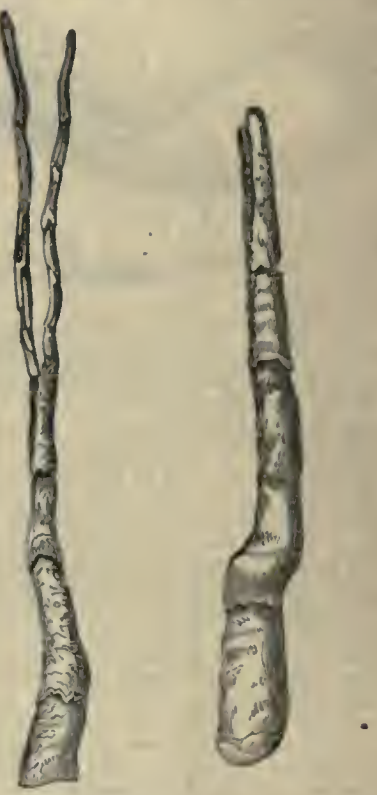
a, tubes with valves in their position at the end; *b*, *c*, two views of the valves; *d*, double operculum; *e*, representation of the protrusion of the two tubes of the animal. (*Phil. Trans.*) G. B. Sowerby.

It is said, probably with truth, that *Teredo navalis* was introduced into Europe from warmer climates. However that may be, it now unfortunately swarms in our seas. The ravages of this apparently insignificant animal are terrible. Ships, piles, all submarine wood-works, are ruinously affected by it: small as it is, it threatened the submersion of Holland by its destruction of the dykes. The living specimens which formed the subject of Sir Everard Home's observations were furnished from one of the royal dockyards. The rapidity of its growth and the destructive celerity with which it works are hardly credible. A piece of deal, after a submersion of forty days, was riddled by them, and some had attained considerable size. Those from the dockyard at Plymouth, examined by Montagu, were in piles which had been recently taken up to be replaced with new; they had not, according to the information given to Montagu, been under water above four or five years, but they were greatly perforated, though they were sound solid oak when they were driven. The only effectual way of preventing the attacks of this animal upon piles appears to be by covering all that part which is continually beneath the surface with short broad-headed nails. The action of the sea-water on the nails produces a strong coating of rust, said to be superior to a copper sheathing.



Wood perforated by Teredines navalis.

Teredo gigantea.—Rumphius, in his 'Amboinsche Rariteitkamer,' gives two figures, here copied, of a species of tubular shell found in shallow water among mangrove-trees. He describes the ground whence they were brought, and the mode in which the large end of the shell is closed, so as to leave little doubt that it was *Teredo gigantea*, though the separation of the two tubes through which the parts of the animal pass out is different from the specimens brought home by Mr. Griffiths. This difference however, as the latter observes, may have been connected with the situation in which the animal was found, namely, shallow water among the mangroves.



Teredo gigantea (Rumph.).

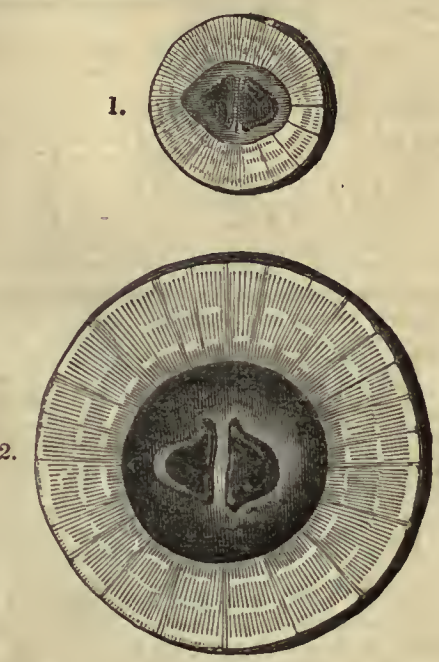
In 1805 Captain Maxwell of the Calcutta East Indiaman gave to Sir Everard (then Mr.) Home, a specimen of this shell, five feet long, but imperfect at both extremities. The captain said it was brought from Sumatra. Several of Mr. Home's friends considered it as a mineral substance, a hollow stalactite, being misled by its radiated structure. Sir Joseph Banks decided that it was a shell, and it was analysed by Mr. Hatchett, who found that it was composed of carbonate of lime and an animal gelatinous substance, which was greater in quantity than in *Chama gigas*, but less than in the common oyster. Mr. Home then applied to Mr. Marsden, who introduced him to Mr. Griffiths, and the paper of the last-mentioned gentleman immediately precedes that of Mr. Home in *Phil. Trans.* for 1806.

Mr. Griffiths relates that a short time after a very violent earthquake that occurred in Sumatra in the year 1797, which produced 'a most tremendous' inundation of the sea, did great damage, and caused the loss of many lives, these shells were procured in a small sheltered bay with a muddy bottom, surrounded by coral reefs, on the island of Battoo. When the sea receded from the bay after the inundation, they were seen protruding from a bank of slightly indurated mud, and two or three specimens were brought to Mr. Griffiths at Padang, by the master of a boat trading between that part and the island, for cocoa-nut oil, sea-slug, &c. Mr. Griffiths then sent one of his servants, a Papooa Coffree, who was very expert at diving, in a small praw. This servant stated that he had found the shells in the before-mentioned bay and in an inlet of the sea, sticking out of rather hard mud, mixed with small stones, sand, &c. from eight to ten inches or more, and from one to three fathoms under water. Both the master and crew assured Mr. Griffiths that the animal throws out tentacula

from the two apertures of the apex of the shell, that resembled the small *actiniæ* adhering to the rocks about Padang, and that the body of the shell was filled with a soft gelatinous flesh, similar to that of the *Teredo navalis*, but this they had washed out on account of its putridity. They said that the shells were in considerable number, and, being gently shaken, easily taken up; but all of them were mutilated more or less, the effect probably of the earthquake, when many large fragments of madrepores, corals, &c. were torn from their seat by the agitation of the sea. More than twenty specimens were brought to Mr. Griffiths, but not one was complete: a portion of the shell with the apex nearly perfect, and another with the opposite closed extremity nearly so, were however procured. The length of the longest of Mr. Griffiths's shells was 5 feet 4 inches, and the circumference of the base 9 inches, tapering upwards to 2½ inches. There were other good ones of smaller size. The large specimen was nearly perfect, having a small part of the lower extremity entire. Most of the shells had adhering to them, about one foot or more from the top, the small cockscomb oyster, small serpulæ, &c.; consequently, Mr. Griffiths observes, they must have been protruded that distance from the hard mud; but the water being thick and discoloured, the people of Battoo had not taken notice of them antecedent to the earthquake. The specimens were milk-white on the outside and within were tinged with yellow. Mr. Griffiths remarks that the large end of the shell is completely closed, and has a rounded appearance; at this part it is very thin. The small end, or apex, is very brittle and divided by a longitudinal septum running down for eight or nine inches, forming it into two distinct tubes, inclosed within the outer one, from whence the animal throws out tentacula. Mr. Griffiths goes on to describe the substance of the shell as composed of layers having a fibrous and radiated appearance, covered externally with a pure white crust, and internally as having a yellow tinge; and the external surface as frequently interrupted in a transverse direction by a sudden increase of thickness, which, he observes, probably indicates different stages in the growth of the shell, although they are at unequal distances, sometimes at six inches, sometimes at four, in the same shell. Many of the shells, he adds, are nearly straight, others crooked and contorted.

Teredo gigantea.

1, the small or upper extremity of the shell, the external covering broken away and showing the termination of the tubes, one of which is broken. 2, a longitudinal section of that part of the shell where the double tubes are formed. 3, the shell complete, or nearly so, the exception being the imperfect state of the upper extremity. (*Phil. Trans.*)



Teredo gigantea.

1, transverse section of shell, giving a front view into the orifices of the double tube, and showing the thickness of the shell at that part. 2, transverse section of shell at the thickest part after it had been polished, showing the structure, and giving a front view of the orifices into the double tube. (*Phil. Trans.*)

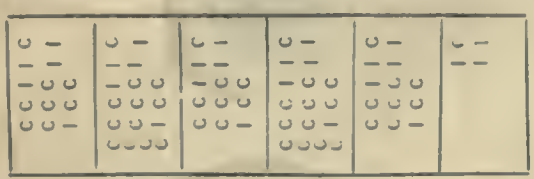
Fossil Teredines.

M. Deshayes in his Tables notes five species of fossil *Teredines* in the tertiary formation, Eocene period of Lyell:—one from the English crag, one from Paris, and four from Belgium. Mr. Lea (*Contributions to Geology*) records a species, *Teredo simplex*, from the Claiborne Beds, Alabama (tertiary). Professor Sedgwick and Mr. Murchison notice the genus in their *Table of Fossils found in the Gosau Deposit and its Equivalents in the Alps;* and also '*Teredo* or *Pholas*,' in their *Table of Fossils of Lower Styria*, as belonging to the 'middle system.' Dr. Fitton, in his *Systematic and Stratigraphical List of Fossils in the Strata below the Chalk*, notes the genus, with a query, from the gault of Kent and Cambridge.

TERE'NTIA. [Cicero.]

TERENTIAN METRES. Few subjects connected with Latin literature have been treated with less success than the principles and laws which govern the metres of Latin comedy. The majority of readers seem to look upon the writings of Plautus and Terence as so much humble prose arbitrarily distributed so as to present to the eye the appearance of verse without its realities. For them it would be better if the whole were printed consecutively, and such an arrangement would in fact be supported by not a few of the existing manuscripts. On the other hand, there have been writers who have laboured to remove the difficulties that obscure the subject, among whom none but Bentley and Hermann appear to have had any success; and what they have done still leaves the subject in a very unsatisfactory position. Even the writer of the Life of Terence, in the 'Biographie Universelle' (published in 1826), has the following extraordinary criticism upon the metres of Terence:—'The sole rule which he observes with tolerable regularity is to end each verse with an iamb; and even this limitation he often disregards, as, for instance, in the terminations *hic consiste; si vis, nunc jam; audio violenter; huc adducam; hanc venturam*, &c. With regard to the other feet, he freely substitutes for the iamb or spondee, a trochee, anapest, dactyl, double pyrrhic, or four short syllables, and a cretic or short between two longs,' &c. This writer thus starts with the false impression that all the verses of Terence are reduced by critics to the single metre, called trimeter iambic; where-

as, in fact, all who have dealt with the subject, except himself, are aware that the poet has at least three forms of verse which end trochaically; and his second exception is disposed of by the more correct orthography *nunc iam*. In England again, so late as the year 1837, we have a scheme of the Terentian meters, which for the commonest of those metres, the trimeter-iambic, gives us the following scale :—



with the additional remarks that *quo quid hunc* may be a dactyl, that *hic quidem est*, *studet par*, and the three first syllables of *voluptati*, may pass for anapests, &c. &c. All this is exceedingly unsatisfactory, and it would be better to abandon the problem as insoluble, than to give currency to extravagancies which would enable us to find in any given chapter of Cæsar a series of trimeter-iambics.

It must be admitted that the metres of the Greek dramatists, and more particularly of the tragedians, gratify the ear with rhythms which, comparatively speaking, are smooth and appreciable. But it should be recollected, in the first place, that the Greek language is distinguished from among other languages by its abundance of words which end in a short syllable, and the advantage to the poet is increased by the large number of instances where these short final syllables have a vowel ending. Compare, for instance, the accusatives singular μουσαν, δουλον, πολιν, ἑαιμονα, with the Latin *musam*, *servom*, *navim*, *leonem*; the nominative and accusative plural ἑαιμονις, ἑαιμονας, with the Latin *leonēs*; the numerals ἑπτα, δεκα, with the Latin *septem*, *decem*; the verbs τυπτετε, τυπτουσι, with the Latin *scribitis*, *scribunt*; the pronouns με, σε, ἑ, with *mē*, *tē*, *sē*. In fact, the Latin language exceeds the Greek in the number of long syllables, as much as the English and German languages exceed the Latin.

A still more important matter is the question whether and how far the written language of the Romans is an exact representative of the spoken language. It seems to be a condition of language in general that its pronunciation should always be passing through a series of changes, and that those changes should consist for the most part in the gradual omission of letters and even syllables. Thus the Roman phrase *mea domina* is in Italian *madonna*; in French *madame*; in English *madam*, *ma'am*, and even *mum* and *mim*. Meanwhile, for the most part, the changes in orthography are slow, and consequently nearly always in arrear of the orthoepy. Thus it will be found that the sounds of English and German words which appear to the eye so weighed down with consonants, are in the mouth of a native tolerably harmonious. Was such the case with the Roman also? We answer with little hesitation in the affirmative, partly because the laws which now govern language can scarcely have been wanting in antient Italy, and partly because we find the point established by several incidental remarks in Latin writers. Thus Suetonius says, in his Life of Augustus (c. 88), 'Orthography—that is, the laws and principles of writing laid down by grammarians—he was not very observant of, but seems rather to follow the opinion of those who hold that we should write as we speak. For as to his habit of changing or omitting not merely single letters, but even whole syllables, that is a common error.' It should be observed too, that Suetonius had himself seen the handwriting of the emperor. (Ibid., c. 87.) Again, Quintilian (*Inst.*, xi. 3, 33) says, 'As, on the one hand, it is essential that every word should be clearly articulated; so, on the other hand, to reckon up, if we may so speak, every separate letter, is painful and wearisome.' In the same chapter he further observes, 'Not only is a coalition of vowels very common, but *some* too of the consonants are disguised (*dissimulantur*), when a vowel follows;' where he must refer to some other letter than *m*, probably the final *s* generally and the final *d* of neuter pronouns. Moreover Priscian, who by the way appears to have written when the Latin language had ceased to be spoken as a living tongue, at times throws out such conjectures as the following:—'I think that *vigil*, *vigilis*, should rather be pronounced *per synecopam*.' We might appeal to Cicero's authority for the fact that a final *s* was frequently omitted in pronunciation. But there are still other arguments in support of the principle for which we are contending. Within the limits of the Latin language itself we find such changes actually in progress—as, *magis*, *uisi*, *ipsus*, *neque*, *atque*, *sive*, *neve*, *viderīs*, *viderunt*, *providens*, *mihi*, *nihil*, *quibus*, *populus*, *tegumen*, *opera*, *potesse*, *mavolo*, *noverit*, *novisti*, *deabus*, becoming severally *mage*, *ni*, *ipse*, *nec*, *ac*, *seu*, *neu*, *vĭdĕre*, *vidĕre*, *prudens*, *mi*, *nil*, *quīs*, *poplus* (compare also *poplicus*), *tegmen*, *opra*, *posse*, *malo*, *norit*, *nosti*, *deis* or *dis*. Principles of etymology would enable us to carry the list out to a vast extent, and this still more if we employed the analogies of the Greek tongue.

Again, the languages which are acknowledged to be derived from the Latin, such as that of the Troubadours, the Italian, French, Spanish, Portuguese, and one portion of the English, by their shortened forms, confirm our views. And this will be found to be specially the case with the French. To those who may express their surprise that the French should thus take precedence in our argument of the Italian, the answer is, that the French is probably derived from the Latin more completely than even the Italian. For the Celtic, Teutonic, and Iberic languages spoken in France before the Roman conquest of that country were of too foreign a character to mix with the language of conquerors or to supply the place of it in the intercourse of the provincials with their masters; whereas in Italy there already existed dialects which were intelligible to those who came from Rome, and for that very reason were not supplanted by that particular form of the Italian language which happened to prevail in the metropolitan city. In the same way the authorised dialect of our own tongue is more likely to become the current language of Calcutta than of Yorkshire. Add to this that the language now called Italian belongs to Tuscany, not to Rome.

Lastly, we find much to strengthen our present argument in the abbreviated forms of writing which were in use among the Romans and are still found in manuscripts. Thus the word *consul* is written *cos*, because the *u* was not pronounced before *s*, as Diomedes expressly tells us. (Putsch., 428.) Again, the word *modo* not unfrequently occupies such a position in the verses of Terence as to seem to require a monosyllabic pronunciation, such indeed as seems also more consistent with its enclitic character. This very word enters into the composition of the Latin *quomodo*, which again in the languages derived from Latin assumes various forms: in the Romance, *com*; in Spanish, *como*; in Italian, *come*; and in French, *comme*. To this we now add the fact that the Romans themselves represented the simple word by the abbreviation *mō*. Again, ·*n*· is the manuscript mode of denoting the conjunction *enim*, a word which must often be pronounced like *en* to fulfil the conditions of Terence's metre. We may observe of this word, as of *modo*, that an enclitic should not attract the attention of the ear. A third example shall be a third enclitic, viz. *quidem*. Bentley himself observed the trouble caused by this word in the verses of Terence (*Andr.*, i. 3, 20), and his remedy is to drop the final *m*, which however still leaves the verse encumbered with a superabundance of syllables. We contend that this also is commonly monosyllable, and on the following grounds. First, the metre of Terence requires it. Secondly, if *ĭtĭdem* has a reduced form *item*, analogy will give us *quem* for *quidem*. Thirdly, the Romans, like the French, did not pronounce the vowel *u* after *q* (otherwise such words, *aqua* for instance, would have had the first syllable long), and they also disguised the final *m*, as Quintilian implies in the passage to which we have already referred. Thus we have arrived at a sound *ke*. Now the Greek language has a word of precisely the same power and character, γε, which we strongly suspect to be the very same word; so that if our suspicions be right, *equidem* and ἑγωγε are of one origin, as well as of one meaning. Lastly, there are reasons still remaining which demand a monosyllabic pronunciation for *quidem*. We have already called it an enclitic, and it appears beyond dispute in that character in the words *equidem*, *siquidem*, *quandoquidem*. Now an enclitic should in its nature sacrifice itself to give tone to the word which precedes it. Yet if we believe the ordinary teachers of Latin prosody, *equidem*, though a corruption from *egoquidem*, or *egquidem*, has the first syllable short. Again, *quando* by itself has the final o common.

to take the most unfavourable view, for in the poets of the Augustan age it would be difficult to find a single example where *o* is short: and in *quandoque*, *quandocunque*, the vowel is always long. But add *quidem*, and they say *quandoquidem* has the same vowel always short. So also *si* in *siquidem*, according to their views, loses its length the moment the enclitic attaches itself to it. If our views be right, the true pronunciation of these three words may be represented by something like *cke*, *quandōke*, *sĭke*; the last corresponding to the Greek ειγε. We will here observe in passing, that our pronunciation of *quidem* suggests a correction of a corrupt passage in Persius, Sat. i. 10:

'Littera. Per me quidem sint omnia protinus alba.'

The current reading is *equidem*; and relying upon one error the editors have allowed the same *equidem* to stand with *dubites* in Sat. v. 45, when the context, as well as grammar, requires *dubitem*.

But to return to the subject before us. It is not uncommon with critics to imagine to themselves that the laws of Greek and of Latin verse are based upon principles essentially different from those of modern languages; the former depending, they say, upon the length of syllables, the latter upon accent. This distinction we believe to be wholly without foundation. We rely little upon the fact that Priscian's treatise headed 'De Accentibus' is only a schoolboy-like scanning of the first lines in the 'Æneid,' because, as has been already said, that writer's authority is not of great weight in what concerns the spoken tongue; and in fact, for the same reason there is little dependence to be placed upon the dogmas of the other so-called grammarians, such as Diomedes. Our views upon this subject are rather derived from the perusal of Terence and Plautus themselves, and are confirmed to a considerable extent by the hexameters of Virgil and the lyrics of Horace. They also seem to be supported by the general principles of language. We will endeavour briefly to state the results at which we think we have fairly arrived.

I. In words of more than two syllables, if, according to the received prosodies, two or more short syllables, exclusive of the final syllable, occur together, the second of those short syllables was slurred over. For instance, in some cases the changing a vowel *i* or *e* into the sound of a *y*, or of a vowel *a*, *o*, or *u* into the sound of a *w*, would be the simplest mode of effecting such a result. Thus *adtrĭbŭĕre*, *pĕrĭīmus*, *consĭlĭum*, would upon our theory be pronounced *adtribŭere*, *peryimus*, *consilyum*, the last of which is confirmed by Horace's use of the same word in his odes, and the Italian *consiglio*, Fr. *conseil*, Sp. *consejo*; and at any rate our pronunciation of the two former is more consistent with the quantity of the vowels than the mode usually adopted, viz. *per-ĭ-imus*, *adtribŭere*. Bentley has himself observed (*Eun.*, ii. 2, 36) that the words *mulier*, *mulieris*, &c. are always so placed in Terence as to have the accent on the first syllable; which, by the way, is consistent with the Italian *moglie*, and the Spanish *muger*. We doubt however whether the dative plural would be found to obey the law laid down by Bentley. In those cases where the second short vowel is followed by a consonant, the abbreviation proposed becomes impracticable, if at least that consonant be really to be sounded. In such cases the right course is probably to drop the syllable altogether. Thus *miseria*, *familia*, and such words, Hermann (*De Re Metrica*) truly says, are to be pronounced with the accent on the first syllable, and this in defiance of the law laid down by all the grammarians, that the accent cannot be carried farther from the end of a word than the antepenult. Hermann has not attempted to reconcile the two assertions, but they fall at once into agreement if we are right in dropping the second syllable, for then the first becomes an antepenultimate; and we are only doing what is common in our own language, as in *évery*, *lóvely*. This principle moreover may be clearly traced in forms acknowledged to be Latin. Thus from *populus* should be formed *populicus*, but that becomes *poplicus* or *publicus*. If *pello* has a perfect *pepuli*, *cado* a perfect *cecidi*; the compounds with *re* should strictly give us *repepuli*, *rececidi*; but we find *reppuli*, *reccidi*. Again, in connection with *opifex* we ought to have *opificium* and *opificina*; but these have been supplanted by *officium*, *officina*. So too the Greek επιπεδον becomes in Latin *oppidum*, as opposed to the *arx*, or citadel; and the adverb επιπεδως takes the form of *oppido*, an equivalent in meaning to *plane*.

II. The accent of a Latin dissyllable or polysyllable will fall upon the penult if long. Where that penult is long by the nature of the vowel, and at the same time the final syllable is short, the accent upon the penult is called a circumflex; in other cases an acute accent. Secondly, if the penult be short, put an acute accent upon the antepenult, always performing the previously mentioned abbreviation, if need be; the necessary effect of which is to give us a long antepenult, if the penult itself be short.

III. The preceding rules dispose of every case except two classes of words, viz. dissyllables with a short penult, and monosyllables. The former are either to be pronounced as monosyllables, or else to be attached to the preceding or following word; and the double word thus formed to be accentuated as a polysyllable. When a word is attached in pronunciation to that which precedes, it has already received in common use the name of enclitic. Hermann, who first observed that there are also words which attach themselves to those which follow, has proposed to give them the name of proclitics. The Greek article, for instance, belongs to this class, as also not unfrequently the Latin hic, haec, &c. The same is true of prepositions, when really prepositions, that is, when they precede their noun; and the Latin *non* or *ne*, like the Greek ου, should perhaps in many cases be pronounced in immediate connection with the following verb, just as we, who are accustomed to place our *not* after a verb, write *cannot* as a single word. Many little conjunctions also may probably require such treatment, as *si*, *ut*, &c. Again, the list of enclitics should be extended so as to include most of the conjunctions which require to be placed second in a sentence, and even conjunctions in general, together with the relative itself when they are forced, if the word may be used, into a second place, as, for instance, in the first line of the 'Æneid,' which acquires additional power by the pronunciation *Troiaé-qui*. In the same way a postponed preposition becomes an enclitic, as in the phrase *altis-de montibus*. In this way many dissyllables and monosyllables will coalesce into polysyllables, and be accentuated accordingly. We even entertain a strong suspicion that a verb in the middle of a sentence must often be treated as an enclitic to give tone to some important word before it. But a statement of our grounds for this belief would require too much room.

IV. The principle of elision will often modify the accent of a word. Thus *cumprímum*, *scribéndum*, *argumênto*, would in ordinary circumstances have the accent as marked. But if elision take place, they sometimes have the accent displaced. In this way the first and eleventh lines of the Prologue to the 'Andria' should be read: 'Poéta cúm-prim ám' adscríbend' ádpulit;' and 'Non yt' dissím'li sunt argúment' ét tamen.' It should also be observed that elision often destroys the initial vowel of the second word, instead of the final syllable of the preceding word, as *nunc tudmst officium*, rather than *nunc tu' ést officium*.

If now the principles we have assumed on the grounds above mentioned be applied to the plays of Terence, we arrive at the result, that the verses, with very few exceptions, acquire the desired rhythm; and that there should be exceptions must be expected where the text of an author is not yet established upon a careful comparison of manuscripts, and where even the transposition of two words will often alter the accent. Moreover it should always be recollected that in the comic drama it may be even desirable to avoid the purer rhythm of verse, and approach somewhat to the prose of natural conversation, as Cicero has himself remarked (*Orator.*, 55). That what we now say may be put to the test, we will give a list of those words requiring abbreviation which most commonly occur, observing at the same time that a word at the end of an iambic trimeter, or after a monosyllable, is often to be pronounced with all its syllables, though elsewhere liable to contraction. Of this an example may be seen in the tenth line of the prologue already referred to, which contains both *noverit* and *norit*.

senex = *sen.* Compare the genitive.
pater = *père.* Compare *parricida.*
soror = *soeur*, as in French.
voluntas = *vountas.* Compare *vīs* = *vŏlĭs* and *invitus.*

lacruma = *larma*. Compare *serment*, from *sacramentum*.
hodie = *oggi*, as in Italian.
dies = *jes*. Compare *jour*, *journée*.
ego = *yo*. Compare Italian.
cave = *cau*. Compare Cicero's story about the word *cauneas*.
tace = *tai*, as in Freneh.
quibus = *quis*. Compare the loss of *b* in the dat. pl. of the first and second deelensions.

tibi = *ti*.
sibi = *si*.
ibi = *i*.
ubi = *ou*.
abi = *ai*.
Compare the Romanee, Ital., Fr., Sp., and *mihi* = *mi*.

jubo = *ju*. Compare the perfect *jussi*.
inde = *in*. Compare the Freneh *en*, and Latin *dein*, *exin*, &c.
redi = *rei*.
magis = *mais*. Compare *mai* It., *mais* Fr., *mas* Sp.
minus = *mins*.
alius = *alyus*. Compare Greek ἄλλος.
facere = *fare*. Compare Fr., Ital., Sp.
vigilare = *vigliare*. Compare Fr., Ital.
vide = *vi*. Compare Fr. *voi-ci*, *voi-la*.
novos = *nous*. Compare Greek νεος, English *new*.
sine = *sin*. Compare Fr., Ital., Sp.
duo = *do*. Compare Greek δω-δεκα, Fr., Eng.
ille, &c. = *il* or *le*, &c. Compare It., Fr., Sp.

bonus = *bon*,
sumus = *sommes*,
as in Freneh.

bene = *ben*.
male = *mal*.
homo = *homme*, as in Freneh.
rei = *re*. Compare the forms of the fifth deelension used by Cæsar, Virgil, &c.
puer = *pur* or *por*. Compare Greek παις, Spartan ποιρ, Latin *Lucipor*.

suus, &c. = *sus* or *sos*.
meus, &c. = *mus*, &c.
tuus = *tus*, &c.
Compare It., Fr., Sp., and also the forms used by Ennius, and in Greek.

fuit = *fut*. Compare It., Fr., and Latin *fore*.
animus = *âmus*. Compare Ital., Fr.
asinus = *ânus*. Compare Fr.
edepol = *epol*. Compare *ecastor*, *ecere*, &c.
legere = *lere*. Compare Fr.
oculus = *oeilus*. Compare Fr.
generis = *genris*. Compare Fr.
aperire = *aprire*. Compare It., Fr., Sp.
opera = *opra*. Compare the form in Ennius, and Fr., Sp.
similis = *sim'lis*. Compare Fr. *semble*, Eng. *resemble*.
tamen = *ta'n*. Compare *tametsi* for *tamenetsi*, and *tandem* for *tamendem*.
aliquis = *alquis*. Compare It. *alcuno*, Fr. *aucun*, from *aliquis-unus*.
hujus = *his*. Compare the abbreviation of *nullius* into *nullius* and *nulli*.
ejus = *is*.

For a more detailed exhibition of these words see *Journal of Education*, vol. ii., p. 344; and on the subject of Latin prosody generally, the same work, vol. iv., p. 336.

It should be added that of modern editors Hermann, Bothe, and Lindemann alone seem to have a distinct idea of the nature of the metres of Terence and Plautus, for all that has been said applies to Plautus as well as Terence. Among older writers, Bentley certainly possessed a clearer insight into the subject than some of his notes would lead one to suppose. That this is the case is proved by an anecdote in Bishop Monk's Life of that scholar. The reverend doctor, dining at a friend's house in London, kept the gentlemen longer over their wine than was thought proper by the ladies in the drawing-room, and added to the scandal when his voice was heard, even above stairs, in what was supposed to be a song to the tune of 'Unfortunate Miss Bailey.' The doctor was only reading to them some specimen of Terence's Comic Septenarius, or, to use a harder phrase, the Iambic Tetrameter Catalectic.

TERENTIA'NUS MAURUS. [MAURUS TERENTIANUS.]

TERENTIUS, or more fully P. TERENTIUS AFER, was one of the two comic poets of Rome whose works have come down to us. The facts of his life were matter of dispute even among the Romans themselves. If we may rely upon the biography attributed by some to Donatus, by others to Suetonius, he was born at Carthage, and became the slave of a Roman senator named Terentius Lucanus, who, pleased with his abilities and handsome person, first gave him a liberal education and afterwards his freedom at an early age. Some, on the other hand, stated that he originally fell into slavery as a prisoner of war. At Rome he lived on terms of intimacy with many men of family, more particularly the second Scipio Africanus and his friend Laelius, who were even said to have assisted in the composition of the six comedies which bear the name of Terence. There were even some who asserted that these two nobles merely borrowed the name of Terence for what was wholly their own. Before he had completed his thirty-fifth year he left Rome, either to avoid the odium which grew out of the suspicion that he had published the writings of others as his own, or to study the institutions and manners of the Greek nation, and thus qualify himself for fresh exertions in the field he had chosen. He never returned, but the accounts of his death were various. Some said that he embarked for Asia, and was never seen from the hour of his embarkation; others that he died on his way back from Greece, where he had translated one hundred and eight plays of Menander; while others again contended that having sent his translated plays in a separate ship, he received the news that this ship with his valued property was lost at sea, and died through grief, in the consulship of Cn. Cornelius Dolabella and M. Fulvius Nobilior, either at Stymphalus in Areadia or at the Leucadian promontory. He was of moderate stature, slender figure, and dark complexion. He left a daughter, who married a Roman of equestrian rank, and a property of six jugers on the Appian road. But another authority reports that he died in the most abject poverty. Eusebius, or rather St. Jerome, places the death of Terence in the reign of Ptolemy Philometor, and this king died in the third year of the 158th Olympiad, or the close of 146 B.C.

The difficulties in the life of Terence are chiefly of a chronological character: the following table of ascertained dates bears upon it:—

218 B.C. Commencement of Second Punic War.
201 B.C. Peace granted to the Carthaginians.
185 B.C. Birth of Scipio Africanus the younger.
184 B.C. Death of Plautus.
169 B.C. Death of Ennius.
168 B.C. Death of Cæcilius (partly on the authority of St. Jerome).
166 B.C. The 'Andria' acted at the Megalensian games.
165 B.C. The 'Hecyra' acted at the same games.
163 B.C. The 'Hautontimorumenos' acted at the same games.
161 B.C. The 'Eunuchos' acted at the same games, and the 'Phormio' at the Roman games.
160 B.C. Death of Æmilius Paulus. The 'Adelphoe' acted at his funeral games, at the expence of his sons Fabius and Scipio.
159 B.C. Consulship of Cn. Cornelius Dolabella and M. Fulvius Nobilior.
149 B.C. Commencement of the Third Punic War.

Thus it appears that the whole period of Terence's life must have been included in the peace between the Second and the Third Punic wars; so that if taken prisoner in war, that war could not have been one between Rome and Carthage. Again, there is a chronological difficulty in the story that the poet, when he offered his 'Andria' to the ædiles, was directed to obtain the approval of Cæcilius; that he accordingly went to the house of the latter, and was coldly bidden to seat himself on a stool and commence reading while the other dined; but that after a few verses Cæcilius was so charmed that he invited Terence to take his seat at the table and dine with him, after which he read through the remainder of the play and filled Cæcilius with admiration. Now the death of Cæcilius, though the date, as we have observed, is in some measure founded upon the testimony of St. Jerome, occurred two years before the 'Andria' was acted. The assertion that Scipio and Lælius assisted the poet is not altogether rendered impossible by the youth of the parties, although Scipio was but nineteen when the 'Andria' was acted, and Lælius was of about the same age with his friend; but the difficulty becomes greater when we find in the prologue of the 'Adelphoe,' that the nobles who were said to give him their aid are spoken of in terms scarcely applicable to men so young.

Be the parties charged to have lent their aid to the poet who they may, it is clear that the poet gives no denial to the accusation, either in the words just alluded to, or in the prologue to the 'Hautontimorumenos.' Even Cicero (*Ad Atticum*, vii. 3) mentions the report that Lælius was the real author; and Cornelius Nepos, who by the way makes the three parties, Scipio, Lælius, and Terence, of the same age (aequales), tells us an anecdote which confirms the report. C. Lælius, says he, happening to pass the Matronalia (a festival on the first of March, when the husband for once in the year was bound to obey the lady) in his villa near Puteoli, was told that dinner was waiting, but still neglected the summons. At last, when he made his appearance, he excused himself by saying that he had been in a peculiar vein of composition, and quoted certain verses which occur in the 'Hautontimorumeros,' viz. those beginning *Satis pol proterve me Syri promissa huc induxerunt.*

The fact of the poet being called Terentius is perfectly in harmony with the circumstance of his alleged master having that name, as it was the ordinary practice of the manumitted slave to take the nomen and prænomen of his late master. On the other hand, it is altogether an error on the part of Orosius to confound the poet with the Q. Terentius Culleo, who, in the garb of a manumitted slave, accompanied the triumphal procession of Scipio after his destruction of Carthage in the year 146 B.C. The name of Afer seems to confirm his Carthaginian birth, unless indeed that assertion be only an inference from the name itself.

Terence acknowledges in the titles to his plays his obligations to the Greek comedians Menander and Apollodorus; but he was not a mere translator, for one of the charges brought against him was that he drew the materials of a single play from two or more of the Greek plays. He was much and deservedly admired by his countrymen, even by Cæsar himself, notwithstanding the phrase in which he speaks of him, as a 'dwarfed Menander' (dimidiate Menander). From Plautus, with whom alone we can now make any satisfactory comparison, he differs most widely. Though Plautus excelled in powerful but ludicrous expressions, he was altogether deficient in the formation and development of a plot. Terence, on the other hand, though even he occasionally introduces the buffoonery of the 'miles gloriosus,' the 'parasitus,' and the 'currens servus,' to gratify the prejudices of his more unpolished hearers, who were better able to appreciate the merits of a boxer or a rope-dancer, still deserves our admiration for his efforts to place before his countrymen the comedy of manners. If he was not always successful, the failure was due to the rude minds of his spectators and the magnitude of a Roman theatre, and perhaps also to the use of masks, which, if always used, must have been a serious obstacle to the best efforts of the comic actor. The best edition of Terence is that of Bentley, Amsterdam, 1727. The modern imitations of Terence may be seen in Dunlop's 'Roman Literature.' George Colman has translated the comedies of Terence into English. There are French translations by Madame Dacier and Le Monnier.

TEREZ. [MEXICAN STATES.]

TE'RGIPES. [NUDIBRANCHIATA, vol. xvi., p. 361.]

TERM (Algebra). A simple term in an algebraical expression means all that involves multiplication, division, and extraction of roots without addition or subtraction. Thus in the expression

$$a^2b^3x^2 - 2abx^3 + \sqrt{ab}\,.\,x^4,$$

the terms are $a^2b^3x^2$, $2abx^3$, and $\sqrt{ab}\,.\,x^4$. But compound quantities are also called terms when they are put in such a form that additions and subtractions are subordinate to subsequent multiplication, division, or extraction. Thus,

$$(a+b)\cdot x^{c+d} + \sqrt{(a^2-b^2)}\,.\,xy$$

has two terms, $(a+b)\,x^{c+d}$ and $\sqrt{(a^2-b^2)}\,.\,xy$. If the form be altered into

$$ax^{c+d} + bx^{c+d} + \sqrt{(a^2-b^2)}\,.\,xy,$$

the expression then has three terms. Most frequently however there is one letter in powers of which the whole expression is arranged, and then all that involves any one power of this principal letter is a term. Thus $a+bx+cx+ex^2$ has three terms, namely, a, $(b+c)x$, and ex^2.

When one quantity is said to be expressed in terms of another, it generally means merely that the first is to be an explicit FUNCTION of the second. Thus, in $x+y=a$, we have expressed $x+y$ in terms of a: deduce $y=a-x$, and we have y expressed in terms of a and x. This is the distinction between y being expressed in terms of x, and y being a function of x: if for instance $y=a-z$, $z=x^2+x$, y is a function of x, but it is not expressed in terms of x, but of z; substitute for z its value, and y is then expressed in terms of x. It is to be remembered that by saying that a quantity is expressed in terms of x, it is not meant that x is the only letter which enters, but that no other letter, if there be any, is a function of x. Thus, in the preceding, where we obtain $y=a-x-x^2$, y is expressed in terms of x if a be no function of x. But if a be a function of x, say x^3+x, then y is not expressed in terms of x, until the value of a has been substituted, giving $y=x^3-x^2$.

TERM. The law Terms are those portions of the year during which the courts of common law sit for the dispatch of business. They are four in number, and are called Hilary Term, Easter Term, Trinity Term, and Michaelmas Term: they take their names from those festivals of the Church which immediately preceded the commencement of each. After the institution of Christianity, all days in the year, Sundays included, were among Christians for some time open for the purposes of litigation. This practice continued even after Christianity became the religion of the Roman empire. Eventually however the courts of law were closed during Sundays, and also during the times of the solemn fasts and festivals of the Church. This regulation was made by a canon of the Church, in the year A.D. 517, and also by a constitution of the younger Theodosius which appears in the Theodosian Code. By these means one vacation was created in the winter during the time of Advent and Christmas, another in the spring during Lent and Easter, and a third during Pentecost. The long vacation in the summer and autumn was also found necessary, and therefore appointed during the time required for collecting the harvest and vintage. The same arrangements were introduced with Christianity into this island. The laws of Edward the Confessor contain the same provisions as to the observance of a vacation from legal business during the fasts and festivals before mentioned. The necessities of a people at that time so universally agricultural seem to have compelled the observance of the long vacation. The Terms therefore consist of what remains of the whole year after the ecclesiastical and agricultural vacations had been taken out of it. It was the commencement of the Terms which was ascertained by the dates of the festivals from which they take their names. Various acts of parliament have been passed relative to the regulation of the Terms. The statute which now determines them is the 11 Geo. IV. and 1 Wm. IV., c. 70, amended by 1 Wm. IV., c. 3, which enacts that Hilary Term shall begin on the 11th and end on the 31st of January; Easter begin on the 15th of April and end on the 8th of May; Trinity begin on the 22nd of May and end on the 12th of June; Michaelmas begin on the 2nd and end on the 25th of November. The Monday being in all cases substituted for the Sunday when the first day of Term falls on the latter day. During Term four judges sit in each court, and are occupied in deciding pure matters of law only, without the intervention of a jury. The fifth judge in each court sometimes sits alone to determine matters of smaller importance or to try causes at Nisi Prius. By the statute 1 and 2 Vic., c. 32, the courts of common law are empowered, upon giving notice, to hold sittings out of Term for the purpose of disposing of the business then pending and undecided before them. These sittings are conducted in the same manner as those during the Term, except that no new business is introduced. The period during which they have the power to do this is restricted to 'such times as are now by law appointed for holding sittings at Nisi Prius in London and Westminster.' These times are appointed by 1 Wm. IV., c. 70, s. 7, and consist of 'not more than twenty-four days, exclusive of Sundays, after any Hilary, Trinity, and Michaelmas Term, nor more than six days, exclusive of Sundays, after any Easter Term, to be reckoned consecutively after such Terms.' The judges are also empowered by the same section to appoint such day or days as they shall think fit for any trial at bar (that is, a trial before four judges of the court) and the time so appointed, if in vacation, is for the purposes of the trial to be deemed a part of the preceding Term.

There is also a provision which enables the judges, with the consent of the parties, to appoint any time not within

the twenty-four days for the trial of any cause at Nisi Prius. The sittings during these twenty-four and six days are called the sitting after Term, and are held for the trials for causes at Nisi Prius for London and Westminster, which places do not form part of any of the circuits. Sittings at Nisi Prius are also held for the same purpose before single judges during Term time, but no special jury cases are taken within the Term. (Spelman, *Of the Terms*; 3 Blackstone's *Com.*, 275.)

TERM (of years), in legal language, signifies the estate and interest which pass to the person to whom an estate for years is granted by the owner of the fee.

A term of years may be created by a conveyance at common law, but no estate is vested in the grantee, nor anything beyond a mere *interesse termini*, until an actual entry is made by him upon the land. The tenant for a term of years is not said to be seised of the land, and the possession is not given to him by livery of seisin. The delivery of a lease for years gives to the grantee a right of entry on the land; when he actually enters, he becomes possessed of the term; the seisin of the freehold still remains in the lessor, and the possession of the lessee for years is then considered as the possession of the person entitled to the freehold or reversion expectant on the determination of the term. (Co. Litt., 200 b.)

By the operation of the Statute of Uses an estate for a term of years may be created without an entry by the termor; as where a freehold estate is conveyed to A and his heirs to the use of B for 99 years, with remainder to the grantor in fee: there the use is immediately executed in B, and the statute instantly annexes to it the legal estate, without any actual entry by B.

A term of years may also be created by devise in a will.

A term of years may be limited to commence *in futuro*, which a freehold cannot; for the freehold is not put in abeyance by the creation of such a term, as it would be by the creation of a freehold estate to commence *in futuro*, but it continues in the grantor. (Co. Litt., 46 a.)

A term of years may be limited so as to cease by a proviso in the conveyance itself, upon the happening of any event, or the performance of any particular act (Co. Litt., 46 a.); and it is usual, when terms of years are created for the purposes of certain trusts, to insert a proviso for the cesser of the term upon the performance and satisfaction of the trusts of the term.

Long terms, as of 500 or 1000 years, are frequently created by way of mortgage, with a proviso for determining them upon payment of the money by a certain day. These are more advantageous than mortgages in fee in one respect, that there does not arise, as in the case of the latter, a separation of the legal estate and the interest in the debt upon the death of the mortgagee. Similar terms are also frequently granted to the trustees of marriage settlements for the purpose of enabling them by sale or mortgage of the terms to raise portions for children and for other purposes. It sometimes happens therefore that, though courts of equity interfere, as in case of mortgages in fee, to enlarge the period of redemption, long terms of years of the kind above mentioned become absolute property. Again, it frequently happens that when a redemption does take place after the time fixed in the original contract, when, according to the theory of mortgages, the estate has become absolute at law, the term may, instead of being surrendered to the owner of the inheritance, be assigned to a trustee for him and his heirs, and retained as an appendage to that inheritance under the name of an attendant term. The advantage of this practice is that it gives the power of defeating the claims of strangers upon the inheritance, by setting up the term as prior in creation, and therefore in right. The right to take advantage of such terms is limited by courts of equity to such incumbrances as the owner of the inheritance had no notice of at the time when he acquired it; otherwise it is obvious that great injustice might be occasioned by the use of them. A term of years attendant on the inheritance is governed by the same rules as the inheritance itself is subject to. The right to it does not go to executors, but follows the devolution of the inheritance. It will not be forfeited as a chattel by the felony of the owner of the inheritance; but if the inheritance escheat, the term will follow it. (3 *Cha. Rep.*, 19.) As to the assignment of attendant and outstanding terms to attend the inheritance, see VENDOR AND PURCHASER.

Terms of years are considered in law not as real estate, but as chattel interests in real property, and they therefore do not descend to the heir of the person who dies possessed of them, but vest in his executor or administrator, like any other chattel; and the principle is the same whatever be the length of the term. (Co. Litt., 9 a.)

Marriage entitles the husband to the terms of years belonging to his wife, as well as to the rest of her personal estate. He may administer to the estate of his deceased wife, and is entitled for his own benefit to her chattels real, whether reduced into possession, or reversionary or contingent; and in case of the husband's death after the wife, his next of kin, and not hers, are entitled to the administration. (Co. Litt., 351 a.) The husband may, during the wife's life, dispose of her chattels real by assignment, but not by will; and if he dies without having assigned them, they will belong to the surviving wife. But if the husband be an alien, he cannot acquire by marriage any right to a term of years belonging to his wife. (*Anon.* 9; *Mod.* 43; *Id.* 104.)

The tenant for years is entitled to the same estovers as the tenant for life (Co. Litt., 41 b.); and, like the tenant for life, he is not entitled to commit waste by cutting down timber, building houses, opening mines, &c. (Co. Litt., 53 a.) He is also punishable for permissive waste, and therefore bound to keep all houses and other buildings on the land in good and tenantable repair. (Co. Litt., 57 a.) If a woman tenant for years commits waste and marries, the husband, having acquired the term by marriage, becomes answerable for the waste. (Co. Litt., 54 a.) A term of years may however, like an estate for life, be granted without impeachment of waste, and such a clause in the grant is construed in the same manner with respect to both estates. When the determination of a term is certain, as when lands are let for 21 years, the tenant is not entitled to emblements, for it was his own folly to sow where he knew that he could not reap. But when an estate for years depends upon an uncertain event, as when it is made determinable on the death of a particular person, the tenant will be entitled to emblements in the same manner as a tenant for life. (Co. Litt., 55 b.; 16 East, 71.)

Terms of years, being chattel interests, are subject to crown debts while they continue in the possession of the debtor, but not in the hands of a *bonâ fide* purchaser for valuable consideration without notice, who has bought before any execution awarded by the crown. (8 *Rep.*, 171.) They are in like manner assets in the hands of the executor or administrator for the payment of specialty and simple contract debts, but not after assignment by him to a purchaser for valuable consideration.

Terms of years, not being estates of inheritance, cannot be entailed, but they may be limited to any number of persons *in esse* successively for life, with limitations over, so as to be inalienable for a life or lives in being, and 21 years after. [SETTLEMENT.]

Terms of years, like life estates, may be merged either by becoming vested in the owner of the freehold, or by surrender to the person in remainder or reversion. [MERGER; SURRENDER.] But a mere *interesse termini*, not being an actual estate, cannot be merged by surrender, though it may be extinguished by release. (Cro. Jac., 619.) It was formerly doubted whether one term could merge in another, but it is now settled that when two terms, granted out of the same estate, vest in the same person, there being no intervening estate, the first merges in the term in reversion. (6 Madd., 66.) Where a term has been created to answer trusts, a court of equity will sometimes relieve against a merger of it, so far as to make it answer the purposes of its creation. (3 Swanst., 603, 608.)

TERMES. [TERMITINA.]

TERMINAL. We cannot say that this term *is* used in mathematics to the extent to which we shall carry it; but the very great convenience which would arise from an extension of its use is sufficient justification for coining a few new meanings. Term is a word of geometry very little used, and signifying boundary or extremity; the words terminal value and terminal form are sometimes used to signify the last and most complete value or form. When a finite expression, added to a certain number of terms of a series, makes up the equivalent of the expression from which the series is deduced, or stands for all the subsequent terms of the series, this finite expression might be

called the terminal expression. Thus in TAYLOR'S THEOREM we have one terminal expression in D'Alembert's form, another in that of Lagrange.

There is also another use of the word, which would convey a distinction much wanting words to express it: we allude to what might be called *terminal language*. All the use of the words infinitely small and infinitely great [INFINITE; LIMIT] is entitled to this name; as follows: When we say, for example, that a circle *is* a regular polygon with an infinitely great number of infinitely small sides, the language used is that of an end arrived at, a transformation actually made: the circle is described as actually consisting of straight lines; and the language is *terminal* (expressive of a boundary actually attained). But the meaning of this language is, or is generally held to be, false: no polygon is a circle, how great soever the number, or how small soever the magnitude, of the sides. The proposition which is really true, that is, over which all shake hands, whatever their notion of infinity may be, is that the terminal proposition, true or false, is one to which an interminable and unlimited degree of approximation may be made. An inscribed regular polygon may, with sides enough, be made to coincide with the circle within any degree of nearness we please to assign: or the following proposition—'the area of the inscribed polygon may be made to differ from that of the circle by less than the *n*th part of the latter'—may be made true for every value of *n* that can be named, however great. Terminal language, properly employed, may be made the means of abbreviation of all those truths whose announcement contains interminable approximation: the development of this sentence is the object of the article INFINITE.

TERMINA'LIA, the festival of Terminus [TERMINUS], celebrated at Rome every year on the 23rd of February. It was said to have been instituted by Numa with the worship of the god himself. The festival was of a twofold character, either public or private, according as it was held at the boundaries between the fields of private persons, or at the boundary of the Ager Romanus. In the former case persons possessing adjoining lands met with their families and servants at the stone which divided the properties, adorned it with garlands and offered sacrifices, and a feast in which the neighbours partook was intended to renew the friendly relations existing between them. (Ovid., *Fast.*, ii. 643, &c.) Dionysius states that down to his time the Romans did not offer any bloody sacrifices on this occasion, but only cakes and fruit. But we have the most authentic statements which show that the assertion of Dionysius can only apply to the early period of the republic, and that subsequently a lamb or a sucking pig was sacrificed. (Dionysius, ii. 74; Plutarch, *Numa*, 16; *Quaest. Rom.*, 15; Horatius, *Epod.*, ii. 59.) The public Terminalia were solemnised in a similar manner by the whole people on the boundary of the Ager Romanus. (Ovid., *Fast.*, ii. 679, &c.)

(Hartung, *Die Religion der Römer*, ii., p. 52; *Dictionary of Greek and Roman Antiquities*, v. 'Terminalia.')

TERMINA'LIA (from *terminus*) is the name of a genus of plants belonging to the natural order Combretaceæ. The species of this genus consist of trees and shrubs, with alternate leaves, which are usually crowded together at the ends of the branches. The flowers are destitute of petals, and are disposed in spikes, which are racemose and panicled: in the lower part of the spikes they contain both stamens and pistils, but in the upper part they contain only stamens. The limb of the calyx is campanulate, 5-cleft, with acute lobes. The stamens are ten in number, arranged in two series, and are longer than the calyx. The ovary contains two ovules, the style is acute, and the fruit is drupaceous, containing only one seed. All the species are inhabitants of the tropical parts of Asia and America: they are numerous, and many of them are used in medicine and the arts.

T. angustifolia, Narrow-leaved Terminalia: the leaves are linear-lanceolate, very thin at both ends, pubescent beneath; the petioles are also pubescent, and have two glands at their apex. This tree is a native of the East Indies, and was formerly called Terminalia Benzoin, as it yields on tapping a gum-resin very similar to benzoin, and possessing the same properties. This gum exudes from the tree in the form of a milky juice, which, on being dried, forms a light whitish substance, exceedingly friable. When gently dried it assumes the form of a white powder, which was in great repute as a cosmetic. It has an agreeable fragrance, resembling gum-benjamin, which in a great measure depends on the benzoic acid it contains.

T. vernix, Varnish Terminalia, has linear-lanceolate leaves, narrowed at each end, and glabrous beneath; the petioles are also glabrous. This plant is a native of the Moluccas, and abounds in a resinous juice, which is collected by the inhabitants, and used in the natural state as a varnish. It is also used for the same purpose in China.

T. Catappa has obovate leaves, tapering to the base, pubescent beneath, and glands on the under sides of the midrib. It is originally a native of the East Indies, but has now become naturalised in the West India Islands. Some botanists have described the West India species as distinct from the Asiatic, but there is no good distinctive character. The drupaceous fruit of this tree is about three inches long, and contains a large seed, which is used for eating and obtaining an oil, in the same manner as the almond. This tree, on account of its thick foliage, is much planted in the tropics for the purpose of forming avenues near houses. The bark and leaves yield a black pigment. Indian ink is manufactured from the juice of this tree. It yields a light durable timber, which is much used.

T. glabrata, smooth Terminalia, very much resembles the last, but the leaves are glabrous beneath and small. The fruit is also of a much less size, oval, and less furrowed. It is a native of the Society and Friendly Islands, and is cultivated by the inhabitants near their huts and in their burial-places. The wood is used in these islands for building boats, making benches, &c., and the seeds are eaten.

T. Bellerica, Belleric Terminalia, has glabrous, elliptic, entire, acute, alternate leaves, and bi-glandular petioles. It is a native of mountainous districts of the East Indies. Its flowers are very fetid. The fruit is reputed to possess tonic, astringent, and attenuant properties. When the bark is wounded a gum flows out, which is insipid, resembling gum-arabic.

T. Chebula is also an East Indian species, it is distinguished from the last by possessing opposite leaves which are pubescent beneath. The fruit of this species is more astringent than the last and is used for the purposes of dyeing. A durable ink is made by mixing the salts of iron with an infusion of the outer rind of the fruit. Both this species and the last are subject to the attacks of insects producing gall-nuts. These galls possess the astringent principle in abundance, and are also used for dyeing. They are called *Cadacay* by the Tamuls.

The genus *Bucida* is very nearly allied to *Terminalia*, and belongs to the same natural order. It is distinguished from the latter genus by its urceolately-campanulate calyx, its didymous anthers, baccate fruit, and angulated putamen. The most remarkable species is the *Bucida buceras*, the ox-horn olive-tree, known in Jamaica as the black olive, in Antigua as the French oak, and in the French Islands as *Grignon*. It has obtuse glabrous ovato-cuneiform leaves, and small yellowish flowers disposed in cylindrical spikes covered with a silky pubescence. It is a native of the West India Islands on clayey soils near the coast. It has obtained its name from the tendency of its branches to shoot out into monstrous spongy excrescences resembling in form the horns of an ox. These excrescences resemble galls in their nature, and are probably produced by insects puncturing the terminal bud of the branch. This tree is remarkable in appearance for its slender crooked branches and tufted leaves, but it attains a considerable size, and its timber is valuable. The bark of this tree contains an astringent principle which is extensively used in tanning.

In the cultivation of species of Terminalia and Bucida a soil composed of loam and peat should be preferred. Cuttings strike freely when placed in a pot of sand and covered with a hand-glass.

(Don's Miller's *Dictionary*; Burnett's *Outlines of Botany*; Bischoff, *Lehrbuch der Botanik*; Lindley, *Natural System*.)

TE'RMINUS, a Roman deity whose worship was said to have been introduced by king Numa Pompilius, when he ordered the fields of the citizens to be separated from one another, and the boundaries to be marked by stones which were to be considered as sacred to Terminus, or as Dionysius calls him, Ζεὺς ὅριος. (Festus, s. v. *Terminus*,

Dionysius, ii. 74.) A careful examination of the worship of this god shows that Terminus was only a surname of Jupiter, who was worshipped under this name as the guardian of boundaries. The stone pillars themselves were regarded as symbolical representations of the god himself, and hence perhaps the severe law mentioned by Festus, that whoever displaced such a pillar should, together with his oxen, be devoted to the god. In the same manner in which the boundaries between the lands of private individuals were marked, the original territory of Rome (Ager Romanus) was separated by pillars from the territory of neighbouring tribes. In the direction of Laurentum there was such a pillar (terminus) between the fifth and sixth milestones from Rome on the Laurentine road. This was the public Terminus. The god had a temple on the Capitol, and the part of the roof just above the symbolical pillar was left open. (Festus; Servius, *Ad Aen.*, ix. 448.) A story to account for this peculiarity is related by Ovid (*Fasti*, ii. 671, &c.) and others.

TERMINUS, or TERM, signifies, in sculpture and architecture, a pillar statue, that is, either a half statue or bust, not placed upon, but incorporated with, and as it were immediately springing out of the square pillar which serves as its pedestal. If they be mere busts, figures of this kind are usually distinguished by the name of Hermæ (Ἑρμαῖ); and busts which, instead of having a circular moulded base, resemble the upper part of a terminus, are called terminal busts. There are many such busts and also some termini in the Townley Collection at the British Museum; among others a double terminal bust of Bacchus and Libera; and a terminal statue of Pan, nearly a whole figure, with a deeply moulded base. The terminus or pillar part is frequently made to taper *downwards*, or made narrower at its base than above, which mode of diminution, the reverse of that employed for columns, was no doubt intended by way of similarity to the general outline of the human figure, whose greatest breadth is at the shoulders. It has been supposed that the earliest statues were merely terminal figures,—upright stones, erected as land-marks and boundaries, the upper end of which was rudely carved into the shape of a head, which form was afterwards retained for occasional purposes after sculpture had arrived at perfection. By modern artists the pedestal part is usually made tapering downwards or narrowest just above its base; when it is called the *gaine*, from its resemblance to the scabbard of a sword.

In architectural design *Terms* are employed in lieu of Caryatides, not however as insulated pillars, but as pilasters forming a small order or attic, or a decoration to gateways, doors, &c. They frequently occur in what is called the *cinquecento* and our own Elizabethan style.

TERMINUS is also now used to signify the buildings for offices, &c., at the extremity of a railroad, whereas those erected at intervals along its course are called *stations*. The establishment of railroads has therefore given rise to a new class of structures, which from their nature and extent admit of being rendered very striking in character and design. One of the most *monumental* architectural works of the kind as yet erected, is the Terminus of the London and Birmingham Railway, in Euston-square,—a Grecian Doric propylæum (distyle in antis, on both fronts) on a large scale, the columns being about 70 feet high. The Terminus at the Birmingham end, though by the same architect (Hardwick), is in the Italian style. (For views, &c. of both structures, see Companion to the 'Almanack' for 1839.) Other termini that may be mentioned for their pretensions to architecture, are—those of the London and Southampton Railway, the one at Nine Elms, Vauxhall, the other at Southampton, both handsome buildings in the Italian style, by Tite; that at Blackwall, by the same architect, and in a similar style; and those at Liverpool, York, and Brighton. The positive necessity for some covered gallery, either colonnade or arcade, and the obvious opportunity afforded for making a spacious portal, either propylæum or gateway, a marked feature in the general design, affords more than ordinary scope to the architect. Now that railroads (*Chemins de Fer*, and *Eisenbahnen*, as the French and Germans term them) have been introduced upon the Continent, they have there also given occasion to many architectural constructions for their termini. Some designs for *Abfahrtsgebäude* (Termini) may be seen in Stüler and Strack's 'Architectonisches Album.'

TERMITI'NÆ, a section of Neuropterous insects, in which Latreille includes the genera *Mantispa*, *Raphidia*, *Termes*, and *Psocus*. These genera however are usually regarded as constituting three distinct families, and will be here treated as such, commencing with the *Raphidiidæ* of Leach, which contains the two first-mentioned genera. The insects of this family have the antennæ slender and composed of more than ten joints; the tarsi have from three to five joints; the wings are nearly equal in size and have numerous nervures inclosing small polygonal cells; the prothorax is long and slender.

The genus *Mantispa* is at once distinguished by the peculiar structure of the anterior pair of legs, which are large, have the tibiæ broad and compressed, and provided beneath with spines; the joints of the tarsi are indistinct, and also furnished beneath with spines: the tarsi of the other four legs are distinctly five-jointed. The antennæ are short, about equal to the head in length, and slender. The prothorax is elongated, slender, and broadest in front. The wings, when at rest, meet over the abdomen.

The *Mantispa pagana* (Fabricius) is rather less than three-quarters of an inch in length, and of a brownish-yellow colour; the wings are transparent, the superior pair have the upper margin yellow. It is found in France and Germany.

In Brazil are species closely allied to *Mantispa*, which differ in having the antennæ as long as the body; the wings are nearly horizontal; the body is depressed and terminated by two little appendices. They form the genus *Hoplophora* of Perty.

In the genus *Raphidia* the body is rather slender, the prothorax is long and almost cylindrical, the head broad and somewhat depressed, and the eyes are prominent; the antennæ are as long as the head and thorax, and composed of about thirty-seven joints. The abdomen is terminated in the female by a long ovipositor. The legs are slender, of moderate length, and the tarsi are four-jointed.

Raphidia ophiopsis is not an uncommon insect in this country: it is rather more than one-third of an inch in length, and the expanded wings measure ⅔ of an inch; the head and body are black, the antennæ and legs are yellow, and the wings are transparent.
